*The Empire Social Hygiene Year-Book*⁹ represents the first annual edition of a record prepared by the British Social Hygiene Council of the work in progress in the British Dominions in combating venereal disease and in advancing the Council's policy of promoting social hygiene. The Right Hon. L. S. Amery, M.P., contributes a preface, in which he calls attention to the value of the educational approach, especially along the two lines of the study of biology and the use of the cinema film. He adds that there are few maladies more susceptible to individual cure or collective prevention, once their existence is frankly acknowledged, and once medical science, social legislation, and personal conduct combine to grapple with them. Sir Basil Blackett discusses imperial citizenship, its responsibilities and privileges, with emphasis on the possibilities arising from closer mutual co-operation. This annual record will in future replace the *Proceedings of the Imperial Social Hygiene Congresses*, which have hitherto appeared biennially. In the present issue Canada has been singled out for special study, and it is proposed that one Dominion or group of colonies shall be the subject of special survey in each succeeding edition. The relation of the Empire to international developments in social hygiene will be dealt with as occasion arises. The bulk of the volume is made up of surveys of the position in various parts of the Empire, which will be found very useful for reference purposes. A series of articles will also attract attention. They deal with such topics as the position of biology in education in Great Britain and the colonies; propaganda methods and results; the future of the film in education; the international aspect of traffic in women and children; the League of Nations inquiry in the East; venereal diseases administration in Great Britain; the International Labour Office and its work for seamen's welfare and coloured labour; and the constitution of a British film institute.

The volume entitled *Clinical Miscellany*¹⁰ comprises a series of twenty-two papers on various interesting cases, by ten members of the staff of the Mary Imogene Bassett Hospital, Cooperstown, New York. Among others mention may be made of a report on two cases of chronic meningococcaemia associated with nephritis; chronic glandular infection of the foci caused by an organism resembling *Flavobacterium pseudomallei* Whitmore; notes on the symptomatology of undulant fever, including one of short duration in a child of 9; and a scarlatiniform eruption followed by desquamation, associated with *Staphylococcus aureus* bacteraemia.

A ninth edition (making 123,000 copies) has been issued of the *Mothercraft Manual*,¹¹ by Miss MABEL LIDDIARD, matron of the Mothercraft Training Society. This society, it will be recalled, was inaugurated by Sir Truby King, and the work is now carried on by Miss Liddiard, with Dr. R. C. Jewesbury as honorary director. The changes in this edition have for the most part been suggested by readers who have been in correspondence with the author at Cromwell House, Highgate, N.6.

Reprints of articles published in various periodicals during 1933-4 by members of the staff of the Middlesex Hospital Medical School have been bound up within one cover. A copy of these collected papers will be added to the Library of the British Medical Association.

British Medical Journal

SATURDAY, OCTOBER 27th, 1934

HEALTH INSURANCE IN CANADA

At the sixty-fifth annual meeting of the Canadian Medical Association, held at Calgary in June last, a report was received from its Committee on Economics, of which Dr. W. Harvey Smith, a past President of the British Medical Association, was the chairman. That report, which contains the Canadian Association's "Plan for Health Insurance in Canada," has now been published in full in a Supplement to the *Canadian Medical Association Journal* for September. It will be found of intense interest and great importance to all those in this country who are concerned with the establishment of a general medical service for the nation based upon an enlargement of the present national health insurance system, as well as to those who in other British Dominions are considering the desirability of setting up some similar system. The report is in three parts. In the first part the meaning and object of health insurance are examined; a description of the development and character of the German, French, and English systems is given; the elaborate report of the American Medical Association is critically analysed; the British Medical Association's proposals for a general medical service are set out; and all the most usual general objections to health insurance are fairly and adequately considered. The second part of the report states fully the present position with regard to medical practice and to organized medical or health services in Canada as a whole and in its several Provinces. The third part contains the Canadian Medical Association's plan for State health insurance, with a reasoned exposition of the principles on which it is based, and of the methods which it is proposed should be used for their practical application. The whole of this third part, and considerable portions of Part I, will be of paramount interest to readers in Great Britain.

It is obvious that conditions in Canada are in many respects similar to those which exist in the United States of America: in others, however, there is a more distinct likeness to those prevalent in this country, particularly in the trend of thought and in administrative practice. This is especially true of the large towns and more populous localities; but even in very sparsely populated areas the needs to be provided for are not dissimilar from those in the Highlands and Islands of Scotland, which have been met by a specially organized medical and health service. The tenor of the whole report makes it evident that its authors have profited by both American and English experience. Negatively, they have seen from the American report on the costs of medical care, with its majority and minority sections and the disharmony to which they have given rise,

how the subject should not be dealt with; and, positively, it is gratifying to note how nearly alike their conclusions and suggestions are to those which have been put forward for development in this country. Indeed, in its general outline the actual scheme proposed is practically identical with that set out in the British Medical Association's "Proposals for a General Medical Service for the Nation"; and the authors quote with approval, and incorporate in their scheme, the principles and conditions which were stated and discussed, as being absolutely essential, by Sir Henry Brackenbury in his address on "The Essentials of a General Medical Service" (reported in the *British Medical Journal* of March 4th, 1933, and since published as a B.M.A. pamphlet) and in his article in the *New England Journal of Medicine* of April last, to which we drew attention in our issue of June 9th (p. 1036). These are, in brief, the right of all registered medical practitioners to be members of the service, the absence of interference between doctor and patient, the appropriate participation of the profession in administration, separation of medical benefit from cash benefits, provision of a full medical service, administration on an area basis and not through approved societies. A further most important agreement with the British Medical Association's "Proposals" is the insistence that the indigent patient must be provided for as an integral part of the scheme, and must be dealt with as nearly as possible on the same lines as those who are able to contribute in the ordinary way.

On the initiation of national health insurance in Great Britain historical reasons and existing facts appeared to justify the establishment of approved societies for the administration of cash benefits, and similar reasons and facts make it extremely difficult, if not impossible, to provide residential institutional treatment as one of the ordinary and universal benefits under a compulsory contributive insurance scheme. Canada is happily free from these particular disadvantages, and, learning from experience in this country and elsewhere, will doubtless be able to establish a more complete and less imperfect scheme. Some less important but not negligible features of the Canadian proposals may be noted. It is recommended that insured persons should pay individually some part of the cost of necessary medicines, and that at least an early, and preferably a periodic, health examination of insured persons should be required. The remuneration of medical practitioners in each area should be according to the method which they collectively select, but the "contract-salary" method should be limited to areas with a population insufficient otherwise to maintain a general practitioner. The importance of the preventive aspects of medicine is emphasized: "It is not enough to render lip-service to the idea of prevention and then leave it all to the public health worker. State health insurance must mean the systematic practice of preventive medicine by the health insurance medical practitioners." Above all—and this is of great significance in view of certain American proposals—the general practitioner and not

the hospital must be the basis and the pivot of the service. "It is *not* intended to make the hospital a medical centre with full-time staffs, but an institution to provide hospital facilities for the use of the general medical profession in the proper care of their patients."

The entire medical profession of the Empire, as represented by the British Medical Association, will desire to congratulate the Canadian Medical Association on this admirable report, and to wish that Association success in pressing its proposals upon the governing and public health authorities of the Dominion and of its Provinces.

INTERACTION OF LABORATORY AND CLINIC

When the first suggestion was made for the allocation of money to a Medical Research Committee, it is easy to imagine that in after-dinner conversations there must have been much shaking of heads among those who knew something about it. Government money spent on research would have to give results which would appeal not only to the university mind but also to the clinicians, and would have to give these results fairly quickly. In all probability the proposal was carried through by the enthusiasm of those who had little more than vision to justify their action. Fortunately Mr. Lloyd George had vision, and so had his immediate advisers, Sir Robert Morant and Sir Walter Fletcher. But the scheme would undoubtedly have met with little success if there had not been men to work it possessed of shrewd and practical minds. One of these, Professor Edward Mellanby, was last year appointed the secretary of the Medical Research Council, and he has now published an account of his work in London and in Sheffield under the title *Nutrition and Disease*.¹ The book has the significant subtitle "The Interaction of Clinical and Experimental Work," and it would be hard to find a more convincing vindication of the value of laboratory research to the clinician when it is carried out under favourable conditions.

Perhaps the most scientifically complete part is the account of Edward Mellanby's contribution to the solution of the problem of rickets, and of May Mellanby's not less important researches on the cause and prevention of dental caries. By now this work is becoming fairly well known, and it need not be discussed again here. The next section deals with simple and toxic goitres, to our knowledge of which the author protests he has made no original contribution. His experiments, however, furnish a very clear picture. When iodine is withheld from a pregnant bitch and from her puppies after birth, the offspring develop large thyroids containing no colloid. The importance of iodine for the pregnant mother is well shown. The hypertrophied thyroid in a dog can be filled with colloid by giving iodine, and, provided the treatment is begun early and the hypertrophy is not excessive,

the gland will become smaller. The giving of cod-liver oil, because of its iodine content, leads to a smaller thyroid gland; similarly, the administration of a large amount of codfish may greatly reduce the size of a goitre and change it to the colloid-containing form. To effect a reduction in the size of a hypertrophied thyroid in an adult dog a good deal of iodine must be given, for smaller amounts merely change the hyperplastic goitre to a colloid goitre. The administration of iodine in exophthalmic goitre produces a similar histological change, causing the thyroid to be filled with colloid and diminishing the symptoms, but there is danger that this newly stored material may be suddenly released. The essential problem of Graves's disease is to discover the mechanism of the release of the active principle from the gland.

In the later part of the book Professor Mellanby deals with the relation of vitamin A to infection and to nervous disorders. Here his argument is directed towards encouraging the investigation of diseases such as retrobulbar neuritis, subacute combined degeneration, and disseminated sclerosis from a new point of view—namely, that of vitamin A deficiency, though he considers that other factors are also involved. His view that the cause of beri-beri and of pellagra is a deficiency of vitamin A and not of vitamin B₁ and vitamin B₂ respectively is of great interest. He argues that the polyneuritis of beri-beri is quite different from avian polyneuritis, since the beri-beri nerve disorders are not rapidly cured by administration of vitamin B₁, and resemble more closely the peripheral nerve changes of vitamin A deficiency.

These lectures carry throughout the stamp of the author's vigorous personality. For example, he protests that "so much ill-judged criticism is levelled against any attempt to open up problems of disease from new angles, both by a certain type of clinician who demands nothing short of a direct cure, and by a certain type of biochemist with no appreciation of the difficulties of biological problems." His main theme, which he seeks to illustrate throughout, is that if the most productive results are wanted from investigators, and if medical treatment is to benefit from money spent on medical research, the investigator must be continually confronted with the problems of disease by having the supervision of patients; specific subjects for laboratory study are suggested in this way, and clinical experience helps in the interpretation of laboratory results. The author's position as secretary of the Medical Research Council gives him a unique opportunity to guide and supervise the application of these views, and the results of the next ten or fifteen years will be awaited with great interest.

In the Lane Medical Lectures, delivered at Stanford University, Professor J. C. Drummond gives an account of the present state of our knowledge of nutrition from a wider aspect.² There were five lectures, and in them is discussed the character of modern problems of nutri-

¹ *Nutrition and Disease. The Interaction of Clinical and Experimental Work.* By Edward Mellanby, M.D., F.R.C.P., F.R.S. Edinburgh and London: Oliver and Boyd, 1934 (ss. ed. net.)

² *Lane Medical Lectures. Biochemical Studies of Nutritional Problems.* By J. C. Drummond. Stanford University Series, vol. III, No. 2. London: H. Milford, Oxford University Press, 1934. (7s. net.)

tion, the part played by protein, the part played by fat, the fat-soluble vitamins, and the water-soluble vitamins. This account, where it covers the same ground as that surveyed in Professor Mellanby's book, is more orthodox—for example, in expressing the usually accepted views of beri-beri and pellagra, though Professor Drummond considers that pellagra is due not only to a deficiency in vitamin B, but also to a deficiency in protein. Many valuable tables are included, such as that showing the results of Corry Mann's experiments on the addition of milk and other supplements to a schoolboy's basic dietary, and the table summarizing M'Gonigle's evidence to explain the increased death rate following slum clearance in Stockton. It will be remembered that families, when moved to better conditions outside the slums, showed a higher death rate because their rents were more and they had less to spend on food. Professor Drummond's lectures will be found a valuable source of information.

BRITISH POST-GRADUATE MEDICAL SCHOOL

On March 17th (p. 487) we published an article on the new British Post-Graduate Medical School, describing the progress so far made with the scheme. It was written by the dean, Dr. M. H. MacKeith. We now have to announce with regret that Dr. MacKeith, within a year of his appointment, has found it necessary to retire from that office on grounds of ill-health. The governing body of the school has accepted this resignation, while expressing sincere appreciation of all the heavy work he has done for the school at its initiation. Public notice of the vacancy is given in our advertisement pages this week. A point to be emphasized is that this announcement is no mere formality: the governing body has decided to throw the post open to the medical profession at large. The dean is the principal executive officer and secretary of the governing body, responsible under its direction for arranging courses of instruction for students at the hospital and school in Ducane Road, Hammersmith, and their attendance at courses elsewhere; for the administrative and financial management of the school; for organizing the supply of information about the school and its work, both in this country and abroad; and generally for advancing the aims and purposes of the school. The inclusive salary of the post is £1,800 a year.

All the professorial chairs and readerships are now filled, and the governing body has been singularly fortunate in the persons appointed to these positions. The new buildings will be completed by the end of this year, and it is hoped that during the first three months of 1935 the professors and their staffs will gradually get the machine into working order. They are due to take over the wards and out-patient department, etc., of the associated hospital from January 1st, so that the school may be open for teaching purposes by about April 1st. Meanwhile the school council has got into its stride, and now holds frequent meetings at which all the details with regard to courses of instruction and so forth are being carefully worked out. It is the earnest wish of all who have at heart the success of the British Post-Graduate Medical School that suitable candidates for the key position of dean may come forward.

INHERITED SMALL-POX

Inherited infection is commoner in small-pox than in any other acute illness, and the study of the effect of the present benign strain of virus upon the offspring of infected mothers, in the current issue of the *Archives of Disease in Childhood*,¹ raises many points of great interest. Drs. J. Pickford Marsden and C. R. M. Greenfield of the London County Council's small-pox hospital service report thirty-four cases of parturient women with small-pox observed by them over the last six years (out of a total of over thirteen thousand patients admitted to hospital during this period). These fell into four large groups as regards the time-incidence of the disease in the baby. Three instances of true congenital small-pox occurred with the rash present at birth, and in each case a period of about ten days had elapsed between the onset of the mother's illness and the estimated time of the appearance of the exanthem on the child. In a second group (eight cases) the child's rash appeared within fourteen days of birth, and in each case the mother at the time of parturition was either in the pre-eruptive stage of small-pox or in the early days of efflorescence, with a time interval of nine to twelve days between the onset of the mother's toxæmia and the appearance of the child's rash. In the third group the child's focal rash appeared on the eleventh or twelfth day of life, and in each case birth had occurred at the time of the outcrop of the mother's focal rash. The fourth group consisted of seventeen infants who escaped congenital infection, although born of infected mothers, seven of them acquiring small-pox subsequent to birth, always with the focal rash on the child fourteen days after the appearance of the mother's rash, and they were all either not vaccinated or vaccinated later in the incubation period. Of the remaining ten cases two were born during convalescence of the mother and found to be immune (unsuccessful vaccination on three occasions); seven babies born late in the mother's illness were all successfully vaccinated and did not develop small-pox; and, finally, twins born during the first week of the mother's illness presented a very interesting phenomenon, for both were successfully vaccinated and one only developed small-pox, on the eleventh day of extrauterine life. This last example of inherited infection gives point to the view, borne out by a study of the whole series, that if not exactly fortuitous, it is more or less of an accident if infection is inherited. All the cases in the first three groups (seventeen) were infected, and all in the fourth group escaped the inherited mode of acquiring the disease. It is also clear that when both mother and foetus are infected they do not pass through the disease simultaneously, and the foetus has its own individual period of incubation. It is nowadays held that the common mode of infection in small-pox is by the respiratory tract, and about fourteen days afterwards the outcrop of the focal rash begins: this time interval was present in those babies acquiring their infection after birth. For those inheriting the disease a shorter period was commonly observed, which corresponds exactly to that found in rare instances of inoculated small-pox, and suggests that the bulk of foetal infections are acquired *in utero* at the time of the mother's "septicaemia" stage—

¹ October, 1934, p. 372.

that is, the stage of generalization of the virus. If the foetus escapes this it may similarly acquire infection at or about the time of separation from its parent, especially if the mother's rash is in its early stage when birth takes place. If the child escapes these two contingencies it escapes congenital infection, but generally, and in the absence of prompt successful vaccination, the disease, acquired by the more usual respiratory route, will show itself after the normal period of incubation. Lastly, there is evidence that if the foetus escapes intra-uterine infection and remains *in utero* until the mother is convalescent from her attack of small-pox it may be born immune. This carefully worked out series of cases will be of great interest to those concerned with the whole mechanism of the inheritance of disease and immunity.

CYSTIC DISEASE OF THE LUNG

Although Fontanus and Nonnus each described a case of bilateral cyst of the lung as far back as 1638, and Wrisberg reported accessory lobes in 1777, congenital abnormalities of the lungs entered the realm of the clinician only with the development of chest radiology. The accessory lobe of the azygos vein has recently attracted much interest, but not sufficient attention has perhaps been drawn to cystic conditions in view of certain diagnostic and pathological facts which Debré and Gilbrin emphasize in a review of the subject.¹ Congenital pulmonary cysts may be unilateral or bilateral, single, multilocular, or multiple; or part or the whole of the lung may assume almost a honeycomb appearance. The condition generally leads to stillbirth or to death shortly after birth, but it may remain latent for any number of years, symptoms, when they arise, taking the form of "major dyspnoeic crises," with cyanosis, violent dyspnoea, and intense inspiratory stridor. In older children and adults, however, dyspnoea is less prominent, and the suffocating attack, associated with pain in the chest, may lead to a diagnosis of spontaneous pneumothorax, which an x-ray photograph, if one is dealing with a single cyst, will appear to confirm. Careful examination of the latter should, however, enable the distinction to be made, for in the congenital condition the collapsed lung will not be seen, or its margin be ill defined; and, further, the air cavity is generally irregular in outline and may show ramifications due to smaller pockets or vessels. It is difficult to explain the sudden onset of symptoms after years of latency and the varying course adopted subsequently. For instance, in one patient the first attack occurred at the age of 66, in another the first attack took place at the age of 6 years, but no other had occurred by the age of 15, only slight dyspnoea being noticed in the interval. The authors point out, however, that a similar course of events is not uncommonly found associated with congenital malformations elsewhere. They also quote an interesting case of an infant whose cyst was seen gradually to increase in size by noting the diminution of the atelectatic area above it by means of serial skiagrams. Cysts may undergo various pathological changes: open into a bronchus; fuse, when multiple; suppurate; and multiple abscesses have been found surrounding a cyst. Malignant disease as a sequel has not been observed

up to the present. Of great interest is the authors' discussion of the condition in relation to bronchiectasis. They point out that the histology of cysts is in the main similar to that found in bronchiectasis, and, basing themselves also on pathological evidence published previously, express the opinion that a congenital abnormality is at the bottom of all cases of bronchiectasis. As in all malformations infection occurs readily in the dilated bronchi (which find it difficult to empty), and this accounts for the onset of symptoms. They consider the rarity with which bronchiectasis follows the very common pneumonic sequels of measles, whooping-cough, and influenza as clinical support of their hypothesis, which incidentally is borne out by a paper by Sayé² describing tubular bronchiectasis (with symptoms) in the left base in each of two univitteline female twins aged 18 years. It would appear that, in spite of its rarity, congenital cystic disease of the lung has to be kept in mind in dealing with spontaneous pneumothorax—especially if it persists unaltered for a considerable time—and with atelectasis, and as a possible cause of abscess.

THE HARVEIAN FESTIVAL

The annual Harveian commemoration was celebrated by the Royal College of Physicians of London on St. Luke's Day (Thursday, October 18th) in the usual manner. In the afternoon the Oration was delivered by Dr. James Collier, and an abridgement of this appeared in the opening pages of our last issue. In the evening the Harveian dinner was held at the College in accordance with Harvey's injunction: "Once every year there shall be a general Feast kept within the said College for all the Fellows that shall please to come." The President, Lord Dawson of Penn, took the chair in his robe of office, and the company included many distinguished guests, some of whom were there in a twofold capacity—as Fellows of the College and as representatives of other bodies. After the memory of William Harvey had been toasted in silence, the health of "The Guests" was proposed by the President. Among those whom Lord Dawson gracefully welcomed by name were Lord Greville and Lord Gorell; the Bishop of Southwark and Chancellor Ponsonby, who had officiated at the service in Marylebone Church that day; Dr. Edwin Bramwell, President of the sister College in Edinburgh; Sir Holburt Waring, President of the Royal College of Surgeons of England; Dr. Robert Hutchison, President of the Royal Society of Medicine; Dr. J. S. Fairbairn, President of the British College of Obstetricians and Gynaecologists; Dr. Ralph Noble, physician to the psychiatric clinic, Royal Prince Alfred Hospital, Sydney; Dr. E. K. Le Fleming, Chairman of Council of the British Medical Association; Professor Edward Mellanby, Secretary of the Medical Research Council; Mr. Hugh Lett, Chairman of the Committee of Management of the Conjoint Examining Board in England; Mr. G. H. Gater, Clerk of the London County Council; Sir Squire Sprigge, Editor of the *Lancet*, and Dr. N. G. Horner, Editor of the *British Medical Journal*. The concern, said Lord Dawson, of those within their fellowship was not only knowledge and its furtherance, but such applications of that knowledge as would adapt it to social needs.

¹ *Presse Méd.*, July 11th, 1934, p. 1113.

² *Anales de Med. Int.*, Madrid, 1932, i, 13.

Medicine must play an increasing part in the constructive statesmanship that had for its aim the health and contentment of mankind. It had to take into account not only the sick man but the man who was up and doing. One by one new services were arising for the promotion of health, and it was here that education had a frontier with medicine. In agreement with Dr. Cyril Norwood he would put physical education in the forefront of the whole educational system, thus bringing the schoolmaster and the doctor into responsible partnership. He coupled with the toast the names of Lord Gorell and Mr. Maurice Healy, K.C., who each replied with entertaining speeches. The health of the Harveian Orator was proposed by the Senior Censor, Professor Langdon Brown, who, speaking as a friend of thirty years' standing, said that Dr. James Collier's Oration that day had given a taste of his quality—that gift of illuminating the dark corners of some problem with a flash of insight. After Dr. Collier's reply the library was visited, where the Harveian librarian, Dr. Arnold Chaplin, had set out a number of valuable books and MSS.

TREATMENT OF MÉNIÈRE'S DISEASE

In a study of forty-two cases subjected to division of the auditory nerve for the relief of vertigo, Dr. Walter E. Dandy¹ shows that the operation can now be performed safely, for there was no fatal case and the attacks of vertigo invariably ceased. The early operations recorded on the eighth nerve were performed for the relief of tinnitus, but the results were discouraging, because the risk was great and the effect on this symptom uncertain. Dandy found that in his series the tinnitus disappeared in twenty cases and diminished in a few others; so it appears that a patient has about an even chance of obtaining relief from this symptom also. The chief technical advance which has contributed to the safety of the operation is the evacuation of cerebro-spinal fluid from the cisterna magna before the cerebellar hemisphere is elevated to expose the internal auditory meatus. After opening the dura mater a spatula is passed over the cerebellum towards the cisterna magna and the arachnoid sheath opened, in order that the cerebro-spinal fluid may be released and aspirated. The cerebellum then can be elevated without using pressure, thus exposing the cerebello-pontine angle. The eighth nerve is exposed by opening the overlying cisterna lateralis. Various methods can be used for the actual division of the nerve, but the essential precautions are to avoid injury of the facial nerve and of the internal auditory artery or any small branches. In three cases Dandy has endeavoured to preserve the residual hearing by dividing only the vestibular portion of the nerve, and he has found that up to the present this has been successful; but in many cases the patient is so deaf in the affected ear that conservation of the hearing is not important and the chance of relief from tinnitus would be of greater value. Transient diplopia followed in four cases, as has been observed by Cairns and Brain, but no satisfactory explanation has been provided for this complication, though it is significant that this symptom is sometimes associated with those of the classical group which com-

prise Ménière's syndrome. There is also a transient vertigo in many cases after the operation; it does not, however, last longer than a week to ten days, usually much less. Dizziness on turning the head may persist for several months,² but the attacks of vertigo always cease. From a careful analysis of the histories of the cases and study of the symptoms before and after operation, Dandy concludes that the lesion responsible for Ménière's syndrome lies in the eighth nerve itself and not in the semicircular canals as has been commonly assumed. He has never observed the same effects after operations in the posterior fossa performed for other conditions, and concludes that the post-operative dizziness is related to the disease, of which the pathology is still unknown. This careful study of a comparatively large series of cases shows the operation to be safe in the hands of a competent neurological surgeon and to be of practical value. In spite of the remarkable success which has been obtained by the perfection of his surgical technique, it may be questioned whether at least two of the conclusions reached by Dandy are valid. In the first place, he says that no other treatment, either curative or palliative, is worthy of mention. A. Hautant² has shown that a proportion of cases of essential vertigo may receive benefit over long periods by relief of intralabyrinthine pressure. The operation is a simple one of opening either the horizontal or the posterior semicircular canal by an exposure through the mastoid process. The good effects of this method of treatment have been confirmed in this country also, and they appear to invalidate the second conclusion of Dandy that the lesion lies in the eighth nerve rather than in the semicircular canals.

A SURGICAL SCHOLARSHIP

A notice by the Association of Surgeons of Great Britain and Ireland appears in our advertisement pages inviting applications for a surgical scholarship to the value of £350, to be held for one year. The object of the scholarship is to enable the holder to pursue a definite line of research or to study surgery in specified clinics at home or abroad. It is designed for the assistance of young surgeons, possibly not yet on the staffs of hospitals, and the wording of the condition applying to it is left vague so that candidates may propose to carry out any kind of surgical work. For example, laboratory or clinical research in some special branch may be proposed alone, or may be combined with travel. The scholarship may also be utilized solely as an assistance in travelling to various surgical centres. A scholar is expected to devote the greater part of his time for a year to the scholarship, but the holding of a part-time appointment does not preclude election to it. Candidates holding such posts as registrarships are not usually considered suitable owing to the amount of time they must give to routine work.

We have received a cable from Professor D. W. Carmalt-Jones, President-Elect of the New Zealand Branch Conference to be held in Dunedin from February 26th to March 1st, 1935, saying that visitors from home will be welcome.

NATIONAL RADIUM

THE ANNUAL REPORTS

The fifth annual reports of the National Radium Trust and the Radium Commission differ slightly as regards the periods to which they refer, the first relating to the twelve months ended March 31st, 1934, and the second to the year August 1st, 1933, to July 31st, 1934. The financial statement of the Commission, however, covers the same twelve months as the Trust. Taken together, the two reports afford important information as to the supplies of radium in the country as a whole, and indicate the uses to which it is being put.

Changes in the membership of the Trust and Commission which occurred in the year under review were noted in these columns last year (*Journal*, 1933, ii, 746). It has also to be recorded now that the retirement of Professor Woodburn Morison created a vacancy in the membership of the Trust, and that Professor A. J. Hall has been co-opted in his place. Moreover, Professor T. G. Moorhead succeeded Lord Dawson as President of the British Medical Association, and therefore became a member of the Trust. Lord Dawson still remains a member, however, in his capacity as President of the Royal College of Physicians of London.

Comparatively small purchases of radium were made during the year under review, totalling 174.295 mg. The amount of the element owned by the Trust on March 31st, 1934, was just over 19 grams. Towards the end of the twelve months the Commission submitted detailed specifications covering in all 1,870.96 mg. of radium and 290 containers. It was clear that in addition to the not inconsiderable amount of radium in hand in containers of types no longer required, a substantial purchase of new radium would be necessary, and negotiations were commenced for this. Since the commencement of the Trust's work a sum of £11,501 has been derived from interest on investments, including £1,535 in respect of the year 1933-4. Against this, the total administrative expenses of the Trust, including £297 for that year (of which £134 represents payments made to the National Physical Laboratory for the testing and measurement of radium and containers), amount to £2,707, leaving a balance of £8,794. Of this sum, £1,500 is on loan to the Radium Commission, being the balance still outstanding of advances amounting to £2,500 made to the Commission in 1929-30.

Two points of a more general nature are included in the report of the Trust. Reference is made to the scheme of research now in progress at the Radium Institute, and under the supervision of a special governing body with the status of a joint research board of the Medical Research Council and the Department of Scientific and Industrial Research, concerning beam therapy, in which a highly penetrating beam of rays is directed upon a malignant growth from a large quantity of radium, termed a "bomb." It is obvious that the results of this investigation may have an important bearing on the work and policy of both the Trust and the Commission in relation to the provision of radium treatment on a national scale. The Cornish radium, which was lent by the Trust to the National Physical Laboratory, has been employed during the year in an attempt to enable gamma ray dosage to be measured in terms of the röntgen, the isometric unit adopted internationally for the measurement of x-ray dosage. Preliminary measurements indicate that in the case of gamma rays scattered radiation plays a prominent part. It appears likely that with further experience it will be possible to specify conditions under which the röntgen can be realized in the gamma ray region with sufficient accuracy for present purposes. The investigation is being continued.

DEVELOPMENT OF CENTRES

The Radium Commission has the following objectives: promotion of the treatment of the sick throughout Great Britain; advancement of knowledge of the best methods of rendering such treatment; and the securing of due economy in using radium therapeutically. The second of these has been dealt with in earlier reports, and the appraisal of results will be dealt with when sufficient statistical evidence has accumulated. The Commission's view that patients should come to well-equipped centres, rather than that radium should be taken to patients, has been strengthened by experience since it was originally set out in the first report of the series. Reference was made in last year's report to the advisability of using in a single scheme all the radium in a centre, including that provided by the Commission with that possessed independently by the centre. The implied unity of organization is less easy at some centres than at others, but the avoidance of wastage of "radium time" is only possible in institutions which can provide bed accommodation for a large number of patients.

The Commission has urged this in previous reports, and in the present one regret is expressed that so few signs of the expansion of bed accommodation at the centres are yet observable. In some centres difficulty in complete pooling arises from the fact that, especially in those instances in which the hospitals are unprovided with "pay" beds, it becomes necessary to make arrangements for a proportion of the hospital's own stock of radium to be used outside its buildings—for example, in nursing homes. In such instances, it is added, the provision of "pay" beds—a practice which has been steadily extending during recent years—may help to solve some of the difficulties attending admission of patients to these centres. Only by avoiding wastage of "radium time" and by provision of adequate bed accommodation can the existing centres perform fully one of their essential functions as units in a national radium service—namely, providing for the needs of a population larger than that normally served by the hospitals in which they have been established. If, it is argued, radium therapy of cancer is confined to the populations normally served by the hospitals selected to act as centres, large areas of the country will remain unprovided for, and it seems essential that arrangements should be made with the authorities of neighbouring voluntary and municipal hospitals to secure a larger clientele for this particular service. The establishment of a larger number of centres is not a practicable alternative, owing to the comparatively small number of hospitals which are provided with all the other services necessary to the proper functioning of a radiotherapeutic centre conceived on modern lines. It is added that the modern tendency to combine treatment by x rays with that by radium may be expected to act as a further incentive to concentration of treatment within the centre. Looking further to the future, and assuming that beam therapy by large masses of radium realizes the hopes of those now having experience of it, an additional reason will exist for organizing the administration of treatment in the way advocated by the Commission.

WORK AT THE CENTRES

Such concentration of radiotherapy at a centre was from the first fully adopted by Aberdeen. The radium officer is not only able to organize the actual details of the radium treatment, but in virtue of his appointment as McRobert research lecturer in malignant disease, comes into contact from the educational side with post-graduates and with medical students in the final year of their studies. The value of courses of instruction in the diagnosis and treatment of malignant disease to men who are going into

general practice cannot be overestimated. This centre has for many years been recognized as a research centre under the Medical Research Council, and the increased radium facilities have enabled it to undertake further investigations. The physics department is showing great activity in the work of the radon requirements of the centre, and in devising solutions to the many problems of radiation dosage which confront the therapist. At Birmingham the General Hospital has been a research centre under the Medical Research Council since 1922, and the help given to actual treatment by the services and investigations in physics have been noteworthy. The Radon Laboratory is under the general supervision of the professor of physics; an increasing use is being made of radon by the centre and by the hospitals in the surrounding district which it serves. Considerable developments in deep x-ray therapy are foreshadowed at this centre. No appreciable improvement in the administrative difficulties having occurred at Bristol, it has been found necessary to withdraw a further 350 mg. of national radium during the past year. The Cardiff centre is well organized, and there is at present no waiting list of cancer patients. The follow-up system at this centre is so complete that nearly all the patients have been traced. Financial reasons prevented the appointment of a specially qualified whole-time radium officer at the Dundee Royal Infirmary, and it has been necessary to return the supply of the national radium and to close the centre.

At the Edinburgh centre it has become evident that a mass unit of one-third of a gram of radium has produced good results, and it has been arranged that a unit of one gram shall now come into operation. A new organization, the Cancer Control Organization, has been formed for Edinburgh and South-East Scotland to assist the National Radium Centre. It has already made a grant of £100 towards the cost of the radium mass unit, and provided financial support for the publication for the first time of the full statistical analysis of the follow-up department for cases of malignant disease. There are two national centres at Glasgow—namely, at the Western Infirmary and the Royal Infirmary. Both continue to do well. The Leeds centre is also doing well, and its allocation of radium has been increased to a total of 1,506.5 mg. The medical director of radium therapy at this centre will now be able to develop and evolve methods for the application of radium at a distance in the treatment of cancer patients. Supplementary x-ray treatment of patients, who in the first instance are treated by radium, will be facilitated in future at this centre by the provision of a new department of deep x-ray therapy.

Owing to the reorganization of the Liverpool Radium Institute and Hospital for Cancer, the National Centre at the Royal Infirmary has not been functioning to its full capacity. In view of the lessening local demand for radium, and of the great need for it in other centres, it has been arranged that a fraction of the radium here shall be returned for use elsewhere. At Manchester the Radium Institute was in existence long before the Commission came into being, and had entered into obligations with neighbouring hospitals, which extend as far away as Chester and Denbighshire. Although national radium is used only within the Holt Institute and the Manchester Royal Infirmary, this practice of using radium outside these institutions cuts across the policy of concentration, which has been one of the main planks in the structure of the Commission's efforts. Sheffield is doing well, and has received a further loan of 250.5 mg. of radium element. A feature of considerable interest at this centre has been the installation of an x-ray apparatus with a new type of x-ray tube, the department being under the direction of the radium officer. By this means he is able to control to his complete satisfaction the dosage to patients who, for the most part, have had radium treatment first. Its

design permits the dismantling of the tube, should the hot filament burn out; a new filament can be introduced and the tube put into action again in the course of a few hours. Bearing in mind the high cost of x-ray tubes operating at high voltages, the performance of these new tubes is being watched with great interest.

Regional centres are operating well at Lincoln, Norwich, Plymouth, Southampton, and Stoke-on-Trent, although the first of these is not yet in full working order. Recognition has been extended to the Royal Infirmary, Bradford, the Burnley Victoria Hospital, the Leicester Royal Infirmary, and the Wolverhampton Royal Hospital, where radium treatment has been in operation for a number of years. These institutions have willingly entered into obligations to the Commission, including the taking of clinical records in proper form, the rendering of statistics annually, and the observance of the rules concerning the care and custody of radium and the protection of the staff which handles it. It is expected that these institutions and others which will similarly receive recognition in the future will, by their returns, make a considerable contribution to the information which the Commission is steadily accumulating as to the value of the treatment of cancer by radium.

ONE-GRAM UNIT THERAPY

In 1932 the Commission placed one-gram units of radium at the disposal of the Cancer Hospital, the Middlesex Hospital, and University College Hospital, in order to find out the utility of these units in the treatment of malignant disease, the work being co-ordinated by a standing clinical committee. This committee has now reported that 251 cases were treated at the three institutions between April 1st, 1933, and April 1st, 1934. All have been treated under identical conditions as regards filtration, radium skin distance, and shape and size of beam, the only variants being the duration and frequency of dosage and the distribution of fields. The majority of these cases allow of histological verification of the diagnosis; they can also be readily observed, and the results of treatment be assessed without difficulty.

AVAILABLE SUPPLY OF RADIUM

The total amount put at the disposal of the Commission by the Trust to date is approximately 20 grams. Of this, 18 grams is on loan to centres, the Medical Research Council, and the National Physical Laboratory, and recently an additional 1.87 grams has been allocated to the national centres at Edinburgh, Leeds, Manchester, and Sheffield. The Commission, by arrangement with the King's Fund, exercises control over the three one-gram units, the property of the Fund, mentioned in the previous paragraph, so that the total amount of radium under the control of the Commission amounts to 23 grams. There are at present thirteen national radium centres and five regional radium centres. There is an additional amount of radium in the country under other control, and it is estimated that the total quantity available for treatment is now about 70 grams. It is expected that more will be required in the future, partly because of the increased number of patients seeking radium therapy and partly because of the spreading opinion that the use of large doses in units and bombs is more effective.

The London School of Hygiene and Tropical Medicine has issued, as a stencilled document of thirty-two pages, a classified catalogue of books in the library relating to natural science. This is the first of a series of class catalogues which it is proposed to issue from time to time: periodical publications and pamphlets are not included. Copies will be sent gratis to interested persons on request to the librarian of the school (Keppel Street, W.C.1).

Nova et Vetera

THE DEATH OF MAURICEAU'S SISTER

To few women is it given to have the manner of their passing recorded for posterity with such wealth of detail and with such eloquence as that with which François Mauriceau, the great seventeenth century accoucheur, describes the death of his sister from ante-partum haemorrhage. A macabre chance decreed that he himself should play the chief part at her death-bed, and in his eager and vivid prose he tells the story.* It is in the nineteenth chapter of the first book, *De la Perte de la Sang*, that he relates the history, and he certainly could have devised no better method of impressing upon his readers the point he wished to make—that a woman attacked by a severe haemorrhage late in pregnancy should be treated by version and delivery without delay. It is of interest to us as showing the slow diffusion of knowledge in those days. Mauriceau himself quotes Guillemeau, who antedated him by about half a century, as having advocated the same treatment, yet he writes as if he had to contend (as no doubt he had) with an almost universal dead weight of contrary opinion, or else no opinion at all save a passive fatalism. When one reflects that "Celuy qu'on croyoit estre le plus habile de tous les chirurgiens qui pratiquait à Paris les accouchemens" could do no better when summoned to the bedside of a woman with ante-partum haemorrhage than to pronounce that "C'estoit une femme morte, à laquelle il n'y avoit rien à faire que de luy faire recevoir tous les Sacramens," it moves one to wonder what must have been the practice of the commonality of the profession in those days. It is difficult for a translation to do full justice to his fiery and passionate rhetoric, for he writes as though the scene were enacted before his eyes, and as if he lived again the hours of suspense he passed at the bedside of his dying sister.

The more to confirm these things I will recount from my own experience a case the memory of which is so painful that the ink with which I now write to make it known that the public may profit by it, seems to be of blood. For on this pitiful and fatal occasion, to my sorrow there was shed before me the very semblance of my own [blood].

It was nine years ago that my own sister, who had not yet reached 21 years of age, was pregnant of her fifth child. Being in good health till then, she had the misfortune to injure herself (though in appearance only slightly), having fallen upon her knees. Her belly struck the earth a little, after which she was a day or two without hurt, which made her neglect the rest which was so necessary for her. But the third day after her hurt at eleven o'clock in the morning, she was suddenly taken with strong and frequent pains in the belly, to which was at once joined a great loss of blood. This caused her to send incontinently for the midwife, but she, not understanding her trade so well as she might, said when she was come, that she must be patient till the uterus was opened by the pains, assuring her for the rest that she had nothing to fear, and would soon be delivered from her trouble, more especially as the child presented favourably. For three or four hours she thus filled her with vain hopes, until (the flow of blood continuing abundant) the pains began to leave her and the poor woman fell several times into a faintness. Thereupon the midwife demanded that a surgeon should come to save her.

They came in haste to my house to warn me, but unhappily not finding me there, went to seek him who was thought to be the cleverest of all the surgeons who practised midwifery in Paris. They led him immediately to the lodging of my sister, it being then about four hours after midday. But having seen the state in which she lay, he contented himself by saying that she was a dead woman for whom there was nothing to be done save to give her the Sacraments, and that she could in no way be delivered. To this the midwife agreed, believing that the opinion of a man so justly famous was not to be doubted. When he had made this prognosis, not wishing to remain longer, he returned to his house leaving

in this deplorable state and without succour this young woman, whose life, and that of her child, he could without question have saved if he had delivered her at the time. This could easily have been done, as one may see by the rest of the story.

After the advice of a man of so great a reputation joined to that of the midwife, all the people who were present believed that since M. Such-a-One could do nothing, there could be no remedy for so great an evil other than to trust in God who alone could do all things. They tried thenceforth as best they could to comfort my poor sister, who was longing with great earnestness to see me, to know if I should pronounce the same sentence, and if her trouble, which grew worse and worse, was without remedy. For the blood flowed continually in great abundance. At last I returned to my house, where they had so long sought me to tell me the evil news. Hearing their tidings I ran in haste to her house, and when I had come there I was met with such a pitiful spectacle that my soul was shaken to its depth with a variety of conflicting emotions. After having regained my senses a little, I approached the bed, where my sister had just received the last Sacraments. She implored my help many times, saying that she had no hope unless from me. I learned from the midwife all that had passed, and she told me the opinion of the surgeon who had seen her more than two hours ago (for it was then quite six o'clock), and I saw that the blood flowed in abundance without ceasing. She had already lost more than three quarter measures and a dozen dishes full in the two hours that had passed since the surgeon had left her. Which blood would have remained in her body had she been delivered at that time, and would have saved her life. I saw also that from one moment to another she was seized with attacks of faintness which grew worse and worse, which told me that she was in greater peril than she would have been had she been delivered two or three hours ago, before she had lost all her strength with the blood which flowed continually. Desirous of knowing if it were true that she could not be delivered, I felt on examining her the internal orifice of the womb opened so that I could easily pass in two or three fingers. I then caused the midwife to examine her again to find out if the orifice were so when the surgeon had said she could not be delivered. She told me yes, and that it had always been in that state since he had left. When she had declared it so, I saw at once her ignorance and what it was that had troubled the surgeon. I told her I was astonished they should both have been of this opinion, as the matter seemed to me quite contrary, and that the surgeon could easily have delivered her then if he had wished, as easily as I could now. And in truth I should have done so on the instant, but my mind so long trembled on the resolution I was forced to take when I had lost hope of all other assistance. What hindered me was not the prognosis of the famous surgeon who had persuaded all those about her that she could not be delivered (for it is temerarious to resist the advice of those held as oracles), but the person of the sufferer who was my own sister and whom I loved very tenderly. So shaken was my soul with passion to see her die before me from a prodigious loss of blood, coming from the same source as my own, that I could not summon my resolution on the instant. This it was which caused me to send again in haste to the surgeon, praying him to return to the house, so that, showing him how easily the operation could be done, and making him confess that there is never any hope in such cases unless it is done at once, I might resolve him to deliver her instead of abandoning her to despair and her child to perish with her. But he would not return, however much one prayed and besought him, excusing himself always that there was nothing that could be done. When they told me this I sent to another surgeon I knew, with whom (if he had come in time) I could have agreed about the need for an operation, as I could have made him confess that it was possible. But by misfortune he could not be found at his house. During all these comings and goings a good hour and a half passed, during which time the blood flowed without ceasing, as also the faintings grew worse and worse. It was then that, seeing myself without hope of the help I had sent for, I took the resolution to deliver her at once. But it was in truth a little too late for the mother. For if I had had strength of purpose enough to do it as soon as I arrived, there was still then a good hope of saving her as I did the child.

Having put two of my fingers within the internal orifice of the uterus, I followed them with a third, and little by little with the ends of all the fingers of the right hand, with which I dilated the orifice enough to give passage to the whole hand. Which can be done easily on such occasions because the abundance of blood mollifies and relaxes the whole womb. When I had gently entered my hand I found that the child presented by the head and that the waters had not yet flowed away, which obliged me to break the membranes with the end of my nails. This being done, I immediately turned the child to take it by the feet, by which I drew it out very easily. And this I did in less time than it takes to count from one to a hundred. And I protest on my conscience that I have never in my life accomplished a delivery more promptly, more easily, and with less violence to the mother, who during the operation complained not the least in the world, though she had at the time good judgement and a full knowledge of what I did to her, but felt much relief after I had delivered her, and thereupon the loss of blood ceased.

The child I withdrew alive and it was instantly baptized by a priest who was in the chamber, but it was too late to save the life of the mother, who died an hour after from a fainting such as she had had before her delivery. The flow of blood in truth ceased, but too little remained in her to withstand the frequent syncope, which she assuredly could have done if this surgeon who saw her first had delivered her three hours before. For since that time she had lost without exaggeration more than twenty dishes of blood, and four or five of these would have sufficed to save her, seeing that she was a young woman of sound constitution suffering from nothing till she was seized with this fatal accident. She was delivered at seven o'clock in the evening, but because she had lost all her blood before the operation it was without avail, and she died an hour after, speaking always with

good judgement till the moment when she died, which was at eight o'clock the same day.

It is interesting to note the importance attached to the completion of delivery, throughout the narrative. Mauriceau was apparently unaware of the efficiency of the undelivered half-breech as a haemostatic plug. Though one shrinks a little from the idea of manually dilating a cervix with a placenta attached to it, yet, remembering the insistence of all these past masters of the art upon the utmost gentleness in manipulation, together with their own extraordinary dexterity, it is unlikely that they did much harm. At all events it was a great improvement on the policy of reaching for one's hat and sending for the priest.

Mauriceau goes on to impute the basest of motives to the surgeon. He does not believe that it was sheer ignorance which drove him precipitately from the lying-in chamber, but "qu'il fuit tant qu'il peut les accouchemens perilleux et sujets à mauvaise suite; ce qu'il fit d'autant plus volontiers, qu'il se rencontra dans la chambre de ma sœur une Dame de considération . . . laquelle il accouchoit ordinairement . . . il aima mieux se conserver l'estime de son ancienne pratique . . . que de faire chrétiennement son devoir." It is a horrible accusation, which one can only hope is false. Whatever the truth of the matter—and criticism after two and a half centuries should be charitable before all things—one cannot but echo most heartily Mauriceau's regret that he could not summon "assez de force sur mon esprit" himself to deliver immediately her "qui étoit ma sœur, que j'aimois très-tendrement." Not yet 21 and pregnant of her fifth child! Poor girl!

A. J. HAWES.

MEDICAL DEFENCE UNION

ANNUAL GENERAL MEETING

At the annual general meeting of the Medical Defence Union the president, Mr. E. Pearce Gould, moving the adoption of the report and financial statement, said the figures showed that during the last year the number of cases dealt with represented more than one for every ten members. The council, he continued, had added to the completeness of its representative character by the appointment of a vice-president who was a dental practitioner. It had also considered certain matters raised by criticism, and as a result there would be submitted to a later meeting that day revised articles of association, which embodied not only the requirements of recent legislation, but indicated more clearly than did the previous articles the current practice of the Union.

The meeting adopted the report and financial statement, and re-elected the retiring members of council, Dr. W. S. A. Griffith, Dr. V. A. Jaynes, and Mr. J. Furneaux Jordan.

REPORT OF THE COUNCIL

This report states that the number of new members elected was 1,080—an increase of ninety-six over the figure for the previous year—and that at July 19th, 1934, the total membership was 17,963. The assistance of the Union was invoked in 1,842 cases. In addition to the usual cases concerning fees and unpaid accounts, members sought legal guidance in such matters as the provision of x-ray examination for osteopaths and the sterilization of female patients. Following the discussion at the last annual meeting, the council was submitting for acceptance certain alterations in the existing articles of association, and also a new clause giving power to the council to undertake a case which had been begun prior to the date on which the member joined the Union but while he was entitled to the privilege of membership of some other society having objects similar to those of the Union. The report points out that while members are afforded protection in respect of claims made as a result of the act or omission of a locumtenent, whether that deputy is a member of any

defence society or not, the same does not hold good in the case of an assistant. The appointment held by the latter is more or less of a personal character, and it should always be possible for the member to ensure that the assistant becomes a member of a defence society.

REPORT OF THE SOLICITORS

The Union's solicitors (Messrs. Hempsons) emphasize the desirability of members taking advice from the Union as early as possible in any proceedings, particularly in cases of complaints under the National Health Insurance Acts. The report states that while representation by counsel or a solicitor is not permitted in inquiries before the Medical Service Subcommittee, a member is entitled to the assistance of the Medical Defence Union in dealing with preliminary correspondence, and this expert guidance in the initial stages often secures a more favourable result than would otherwise be obtained. A total of 148 cases was referred by the council during the year; twenty-six of the fifty-seven involving charges of negligence were a direct response to members' claims for fees, and fifteen of these were abandoned when the defendant learnt that the Union was concerned. Among the cases of alleged negligence were several claims for damages resulting from a swab being overlooked at operation, and a claim in respect of loss of sight against a member who, instead of referring the patient to his ordinary doctor or panel practitioner, gave wholly gratuitous and friendly advice. As regards the former, while the checking of swabs is, in the opinion of the solicitors, a nursing duty for which the nurse should be responsible, the court has not yet recognized this, nor has a clear-cut decision been obtained. Members attached to hospitals, therefore, should make sure that there is a reliable and accepted system for the checking of instruments and swabs.

The total income of the Union for the year 1933 was £19,026 11s. 9d., and the expenditure £16,044 4s. 5d.

AMENDMENT OF ARTICLES

At an extraordinary annual general meeting of the Union held the same day the revised articles of association, with certain amendments made by the meeting, were adopted.

New Zealand

[FROM OUR CORRESPONDENT IN WELLINGTON]

The Cancer Campaign

The annual meeting of the New Zealand branch of the British Empire Cancer Campaign was held in Christchurch, and the reports of its various activities received much public attention. The special research work at the medical school is to be continued for seven years under the direction of Dr. A. M. Begg. The cancer clinics, conducted once, or, in some instances, twice a week by the society in the larger hospitals, are most successful in attracting patients and in the results secured, which are steadily improving, and are a bright and encouraging contrast to those obtained less than a decade ago. The records and statistics have been most carefully prepared, and are now numerous enough to warrant the beginning of statistical research. At the time of writing Dr. Moran of Sydney, adviser on radiotherapy to the Government of New South Wales, has arrived in New Zealand, and, under the auspices of the New Zealand branch of the Campaign, will address medical men and also the laity on the cancer problem. He believes that as in some strange way civilization has brought greater susceptibility to the disease, so the evolution of man's intelligence must in time produce a cure. In the meantime, here as elsewhere, the medical profession, with all the means it possesses, must do its utmost to relieve suffering while researchers slowly track down the disease.

Influenza in Great Britain and New Zealand

The Director-General of Health for New Zealand (Dr. M. H. Watt) refers, in his annual report for the year ended March 31st, 1934, to the recurring question whether an epidemic of influenza in Great Britain is in due course followed by an outbreak of the disease in New Zealand. He summarizes recent evidence, which indicates that while Australia and New Zealand follow each other closely in this respect, there is no such relation between Great Britain and the Antipodes. Indeed, for the period 1923-8 the curve for England and Wales takes a diametrically opposite course to those for Australia and New Zealand. Thus 1924 and 1927, peak years for England and Wales, were marked by a low incidence in Australia and New Zealand, while 1923, 1926, and 1928, with few influenza deaths in the former, proved to be years of heavy mortality in the latter. Subsequent to 1928, however, there is a general similarity between the curves, peak years and years of low incidence being the same for the three countries. The evidence, Dr. Watt considers, is altogether inconclusive; all that can be said is that influenza does not necessarily or even usually invade New Zealand from Great Britain. The period of time which separates the winter epidemics of the two countries further supports the belief that these seasonal outbreaks are purely local affairs, due not to any importations of fresh virus, but rather to a lighting up of an infection which is always present and continues to smoulder until it is activated by suitable environmental and biological conditions.

Infant Mortality and Expectation of Life

New Zealand's low death rate and high expectation of life have recently received added prominence from the use made of them by Drs. Dublin and Lotka, United States statisticians. The expectation of life in the male is 65 and in the female 68, and the comment is made that New Zealand has already come close to the possible top score in the present state of medical and sanitary knowledge. The mortality in the first year of life in the white

population of New Zealand is only 38.35 per 1,000 for males and 25.48 for females. The corresponding figures for the white population of the United States are 60.86 and 48.21. The report and commentary are a plea for close attention in all civilized countries to infantile mortality. As the child grows older it enters a zone of low mortality with a minimum of not much more than 1 per 1,000 per annum about the age of 10, and the opportunity for improvement here is small. Mortality figures again increase in later life, but they cannot be reduced by sure methods such as are available against infectious diseases and nutritional and other diseases of infancy. Some years ago Dr. Dublin prepared a hypothetical life table at a time when the actual expectation of life was 57, and he gave 63½ years as the expectation of life to be attained some time in the future in the United States, this estimate being based entirely on New Zealand figures. He now thinks that he was too conservative in his prognostication, and that an expectation of 70 is now attainable. It would appear, however, that the conditions of life on a continent such as America are not exactly comparable with the conditions on an island country such as New Zealand, and differ climatically, socially, and economically.

Doctors and Investments

Government Commissions are inquiring into the operations of nineteen interlocking trust companies in New Zealand, New South Wales, and Victoria. The evidence has caused what the newspapers call a sensation. One of these companies is known as the British Medical Investment Trust Limited, conveying a suggestion that it is connected with the British Medical Association—which is a compliment to the B.M.A., no doubt! A large number of medical men will probably now read with close personal interest the evidence given of the ramifications of investment companies, and the mysteries and secrets of high finance, and for a time will be highly discriminating in their choice of investments.

School Dental Service

An attempt is now being made to reach the country schools, often scattered very widely apart, by means of a new type of trailer dental clinic. The interior of the trailer car is 14 feet by 7½ feet, the walls are of steel, and the interior is smooth with rounded angles. Natural lighting is provided from a bay window, which forms one end of the car, but lighting and also heating are available from hydro-electric supplies, which serve even sparsely populated districts. The clinic is towed by a motor lorry or car.

India

Annual Meeting of the Assam Branch

The annual meeting of the Assam Branch of the British Medical Association was of exceptional interest this year, for it celebrated the union of the Northern Bengal Division with the Branch. As the retiring president, Lieut.-Colonel J. Morison, director of the Shillong Pasteur Institute, pointed out at the dinner, since its inauguration in 1908 the Branch has had a fine record of public service. It initiated the movement that resulted in the building of the Pasteur Institute, and thus gave to Assam a fine centre for medical research. Its members had also started the campaign against kala-azar which was later so effectively developed by the Government. Moreover, it had actively supported the interests of the tea-garden coolies and of the skilled and experienced native licentiate. The Governor of Assam, Sir Michael Keane, added that

the Branch had achieved many miracles, of which the most recent was the anti-cholera crusade along the banks of the Brahmapootra and the Barak, largely due to the close co-operation which existed between it and the Government and the Pasteur Institute. The meeting was held on four days at Shillong, and the morning of one day was spent at the Pasteur Institute, when Lieut.-Colonel Morison gave a very interesting demonstration of the recent discoveries in respect of bacteriophage types, the micro-manipulator, and the preparation of antirabic vaccine. Fruitful discussions were held on cholera, diphtheria, the treatment of malaria by atabrin, the control of this disease in a group of tea-gardens, and public health and sanitation in tea-gardens. The discussion on atabrin proved so vigorous that the subject will be brought up again at the next annual meeting. A visit was also paid to the Welsh Mission Hospital, with its up-to-date x-ray and electrical department and new operating theatre and dark room. In his presidential address Lieut.-Colonel Morison discussed the Indian Medical Council Act, and mentioned the responsibilities which were carried by the Assam Branch, particularly in respect of the advice it was often called upon to give to the Government. He commented on the difficulties attending lunacy certification in Assam, and then gave a general account of the activities of the Pasteur Institute. Daring experiments had been conducted with phage in the prevention of cholera, and the president gave details of the successes that had been achieved and the conclusions that were being reached. Since there was a possibility that phage might prove to be a factor also in influenza epidemics, and in other great epidemic diseases with well-defined cycles, fascinating and important issues still remained for further investigation. The *Proceedings* of this annual meeting have now been published by the Indian Tea Association; they include reprints of the chief speeches delivered, which are in many cases of considerable clinical and scientific interest, particularly to those whose work lies in tropical countries.

Calcutta School of Tropical Medicine

The annual report for 1933 of the Calcutta School of Tropical Medicine and the Carmichael Hospital for Tropical Diseases records some important developments, designed to remedy to some extent the crippling due to inadequate accommodation for a steadily growing work. Thus the All-India Institute of Hygiene has made room for a continuation, on a smaller scale, of a kala-azar inquiry, its predecessor having been closed in March, 1933. Dr. Muir's research laboratory is also housed there now. The Pasteur Institute of Bengal has been transferred to commodious premises in another part of Calcutta, whence it now issues the antirabic virus to centres throughout Bengal. This decentralization is not only an economical move, but it has also rendered antirabic treatment much more widespread through the Province. The museum is being enlarged, and its educational value has been thereby enhanced. The Carmichael Hospital, with its ninety-two beds in the open wards and its fourteen in private cabins, represents a research hospital attached to the school. Such cases are selected as will be suitable for post-graduate teaching in tropical medicine or for research work. Even so, there is always a long waiting list of candidates for admission, it being realized that the whole resources of the school can be brought into action for each case. The reports of the various professors and departmental heads make interesting reading. For example, complement-fixation tests in malaria have continued, and it has now been established that cases of acute or subacute lymphangitis tend to exhibit two different types of immunity response. In one

type the finding is a positive complement-fixation reaction associated with an eosinophilia, the total white count and polymorphonuclear percentage being within normal limits. In the other type the finding is a negative complement-fixation reaction with a polymorphonuclear leucocytosis. It is concluded, accordingly, that there are two distinct types of attack in such cases, which have been designated the toxic and septic types respectively. Repeated testings of cases of acute or subacute lymphangitis, with a positive complement-fixation reaction, has demonstrated that as the attack passes off the reaction becomes negative. A new investigation of anaemia and respiratory diseases—chiefly pneumonia—has been started in the Assam tea-gardens. With regard to cholera, results have been obtained which establish the aetiological relation to this infection of the so-called cholera-like non-agglutinating vibrios. A comprehensive work on the antigenic structure of the different phases of the vibrio is nearing completion, and is expected to throw much light on the puzzles connected with the serological reactions of vibrios. The leprolin test, which originated in Japan, has proved of value in determining the type of leprosy, in making a prognosis, and in estimating the value of treatment.

Ireland

Royal College of Physicians

At the annual meeting of the Royal College of Physicians of Ireland Dr. J. A. Matson was elected President and Dr. W. Boxwell Vice-President. A special service for doctors and medical students was held in St. Patrick's Cathedral on October 18th, and in the evening the annual St. Luke's Day dinner was given in the College Hall, when there was a large attendance of Fellows and guests.

Home Hygiene

At the inaugural meeting of the clinical session Dr. Robert E. Steen, physician to the Meath Hospital, Dublin, read a paper on home hygiene, in which he said that the system of school hours in this country was very detrimental to the health of children. A child was continuously worked after entering the school at 9.30 a.m., except for a short break at midday for a piece of bread or for bread and milk. The result was that by the time the child reached home, at 3.30 p.m. or later, its appetite in many cases was gone, and the hot meal which it should have received at midday, and which should be its mainstay, became little more than a farce. The tendency was for the child to eat more heavily later in the evening, and tea, which should be the lightest of the three meals, became the chief meal of the day. Discussing the milk supply, Dr. Steen said that a quiet effort had been made in the last ten years to make milk reasonably safe for consumption. It was only within the present year that a Bill had been introduced to prevent vendors from selling milk under misleading titles. Until the Bill became law the old conditions would exist, and a man might sell milk teeming with microbes under the title of Grade A without any penalty. There were a large number of milk producers who sold what might be regarded as a reasonably safe milk. They had joined together to form an association known as the Tubercle-Free Milk Producers' Association, which meant that every cow in the herds was periodically subjected to vigorous tests. Such milk cost no more than ordinary milk, and those dairies should be encouraged by receiving public support. Professor J. W. Bigger congratulated Dr. Steen on his address, and said that while the preventive aspect of medicine was being more and

more emphasized Government authorities had not utilized the knowledge that had been acquired by the profession. If he himself were so unfortunate as to be appointed dictator of this country for one year he could reduce the number of deaths from diphtheria by 90 per cent., and in the same proportion he could also reduce the deaths from bovine tuberculosis. He could guarantee to eradicate all forms of tuberculosis within twenty years by utilizing the knowledge which the medical profession now had. Much was being done by medical officers of health, and in that connexion it was gratifying to realize that almost all counties in the Free State had full-time county medical officers of health. A great deal of preventive work could best be done in the homes. The old-time family doctor had many virtues. He would like to sketch out a scheme for reviving the position of family doctor—a scheme applicable particularly to the middle classes. The middle classes were medically neglected, as compared with the rich, who could look after themselves, and with the poor, who were well cared for. Doctors were anxious to help the public and to give the public the benefit of their knowledge.

Treatment of the Mentally Defective Child

In the course of his monthly report to the Grange-gorman and Portrane Mental Hospitals Committee, Dublin, the resident medical officer, Dr. J. O'C. Donellan, refers to the difficulty of giving proper care to mentally defective children. In the two institutions there are eleven such children. Their care is a problem, since their number is not sufficient to warrant the setting aside of special wards. Dr. Donellan suggests that a central home for these defectives should be established, where patients from all parts of the country could be dealt with. Some of these cases could be much improved under judicious management and training, and those of the worst type would receive appropriate attention, which it was impossible to provide in a general mental hospital.

England and Wales

A Twenty-First Anniversary

King's College Hospital has now occupied its present site in the South of London for twenty-one years, and a service in commemoration of this anniversary was held on October 18th at the Church of St. Clement Danes. The Archbishop of Canterbury gave an address in which he said that the removal of the hospital twenty-one years ago had been a wise step. It was placed in healthy surroundings, and its greater usefulness was shown in the increase in the number of in-patients treated. Since the foundation of the hospital ninety-four years ago there had been an amazing advance in medical and surgical knowledge. No single step in the effort to save life had been comparable to that of the discoveries of Joseph Lister, who for fifteen years held the chair of clinical surgery in King's College. His Grace, referring to the voluntary hospitals, said that while he was not forgetful of the work of the hospitals maintained by public authorities, the fact that a hospital stood for voluntary zeal gave it a tone and atmosphere of its own. The number of in-patients of King's College Hospital last year was 6,779, compared with 2,991 in 1912, the last year on the old site. The out-patients increased in the same period from 37,009 to 306,248. The annual expenditure has risen from £22,599 to £104,000, but the mortgage of £80,000 which had to be raised to carry on the work during the war has now been reduced to £57,000. The next step in

the completion of the hospital is the addition of a final side to the administrative block, forming the nurses' home, at a cost of £25,000. The present hospital was actually occupied by patients on October 13th, 1913, when the casualty department was opened and two wards were made available out of the 384 beds forming the present complement. The removal from Portugal Street to Deamark Hill was made possible by a gift of a site of twelve acres by the late Lord Hambleden. The medical school, which had hitherto been incomplete, was finished and opened by Prince George in 1933.

Congress on Life Assurance Medicine, 1935

An international congress on life assurance medicine will be held in London next summer under the patronage of H.R.H. the Duke of York and the presidency of Professor W. Langdon Brown. It is the first congress of its kind since 1903 and the first to be held in this country. On the evening of Tuesday, July 23rd, a reception will be given to the delegates, and after the formal opening ceremonies on July 24th discussions will be held on methods of estimating risks and on the prognosis of hypertension. On July 25th there will be discussions on the acceptance of glycosurics, and on gastro-intestinal ulceration and life assurance, with a conference banquet in the evening. The morning of July 26th will be given up to a discussion on the role of health service in life assurance, and the afternoon to short papers. On Saturday, July 27th, there will be excursions. Details of the names received for discussions and of the short papers, and also of the various social functions in connexion with the congress, will be circulated later. The subscription, including banquet, etc., and a copy of the transactions, is £2; for lady associate members (limited to one for each member of the congress) £1, to include banquet and social functions only. The hon. secretary is Dr. Otto May, 142, Holborn Bars, E.C.1; the chairman of the executive committee is Dr. Theodore Thompson; and the hon. treasurer, Dr. Stanley Bousfield. For practitioners resident in Great Britain and Ireland, membership is restricted to members of the Assurance Medical Society and to such other practitioners as are interested in life assurance and whose application for membership is approved by the congress committee.

Chelsea Clinical Society Annual Dinner

On October 16th the annual dinner of the Chelsea Clinical Society took place at the Rembrandt Hotel, S.W., the president, Dr. Charles Sundell, being in the chair. There was a good attendance of members and guests. The toast of "The Society," coupled with the name of its president, was proposed by Colonel T. McDonald Banks, Director-General of the Post Office. He said that, on the principle of the cobbler sticking to his last, he could perhaps best occupy the time by telling those present something about his own work. The Post Office employed a quarter of a million people, and with the exception of the L.M.S. was the largest single organization in the world. Their chief medical officer, Dr. H. H. Bashford, was doing very fine work in watching over the health of all its servants. Everyone who applied for employment was thoroughly examined medically, and elaborate records were kept of the state of health of every member of the organization. It was, incidentally, worth noting that messenger boys applying for work were now, on the average, 16 lb. heavier and one and a half inches taller than they were before the war. The sick records would, it was hoped, prove of considerable statistical value, as there was enormous material available for mass investigation. As an example of this, the effect of an

antitubercular vaccine was tried on 800 Post Office volunteers all over the country, and a similar investigation was going to be made this year. High blood pressure might well form a suitable subject for statistical research. An investigation of the occupations and hobbies of the modern generation was particularly interesting. Out of 250 young employees only eight had no outdoor amusement, seventy-two were cyclists, forty-one were swimmers, fifty-nine campers, and sixty-three played cricket or football. This seemed to show, in contrast with the foreign "youth movement," that as a race the British did not have to be dragged into athletic activities, but were well able to look after themselves. The speaker concluded with a tribute to the president. In reply, Dr. Sundell related a personal anecdote concerning Colonel Banks and the Post Office, and made passing references to the Minister of Transport, the Treasurer's attack of influenza, and the campanological duties of the chairman—a silver hand-bell serves as curfew in cases of long-windedness. Future subjects for discussion in the society included "slimming" and, as a suitable follower, "embalming." Proposing the toast of "The Guests," Dr. Henry MacCormac mentioned Dr. Robert Hutchison, Dr. Hope Gosse, Lord Horder, and Lieut.-General Hartigan, Director General of the Army Medical Services. The last two briefly replied.

Winsley Sanatorium

Important extensions to Winsley Sanatorium were opened by Lady Lansdowne on October 10th. This sanatorium, which serves the three local authorities of Bristol, Wiltshire, and Bath, was opened in 1903 as the result of intensive propaganda by the Gloucester, Somerset, and Wilts branch of the National Association for the Prevention of Consumption. The splendid pioneer work of this association stands in some danger of being forgotten, but the presence of Dr. Lionel Weatherly at the opening of the extensions recalled the time when the foundation stone was laid more than thirty years ago and he was chairman of the Executive Committee. Dr. P. Watson-Williams, who was the honorary treasurer of this branch of the association, was also at the ceremony. The admirable beginning made by the association has expanded, until the increasing needs of those patients for whom local authorities are responsible has brought the cities of Bristol and Bath and the county of Wiltshire into the position of maintaining nearly the whole of the available beds. The Marquess of Lansdowne presided at the meeting which preceded the opening ceremony. Alderman J. E. Jones (of Bristol) gave a short account of the progress of the institution, explaining the urgent need for the extensions, which included a new administrative block, a new nurses' home, and a recreation room for female patients. Additional space has thereby been gained in the medical unit, and used for the provision of out-patient rooms, a throat department, and dental treatment rooms. Dr. Lionel Weatherly spoke of the finding and purchase of the site and the early days of the sanatorium, which was founded on philanthropy, rate aid, and self-help. The institution is now taking nothing from the philanthropic purse, and is saving money every year. Lady Lansdowne made a charming and brief speech, dwelling especially on the work of the nurses and the need for housing them well. She was presented with a golden key, with which she proceeded to open the new buildings. It is interesting to note that the new buildings have been entirely paid for out of capital funds, and that although the estimated expenditure was £17,361 the complete cost was only £17,244. The plans were drawn by Messrs. W. S. Skinner and Sons of Bristol, whose hospital designs here and elsewhere in the neighbourhood are unsurpassed for simplicity and workableness.

Reports of Societies

UNSETTLED PROBLEMS OF NEUROSYPHILIS

Instead of delivering a presidential address in the Section of Neurology of the Royal Society of Medicine on October 18th, Dr. S. A. KISSNER WILSON introduced a discussion on some unsettled questions of neurosyphilis.

Dr. Wilson recalled that he was one of a number of medical men visiting Paris at the invitation of the Faculty of Medicine in the spring of 1905, when the great subject of discussion was the new discovery of the organism of syphilis. He wondered whether very much advance had taken place since then. Things were "hang'ng fire" to some extent to-day because not nearly enough was known about the organism. It was not even known whether it was a low form of plant life or of animal life, whether it could be cultured or not, whether or not it was a filterable virus. It had been pointed out years ago by McDonagh that the organism had never, or very rarely, been seen to divide. Cultures seemed to die for no ascertainable reason, as though there were some undiscovered intermediate phase. Nothing was known about the laws, if there were any, whereby syphilis was inherited. It was, perhaps, wrong to talk about inherited syphilis; there was congenital syphilis, but not cellular inheritance. Had these years of advancing knowledge made any difference to the incidence of congenital syphilis, or to its sequel, in 3 or 5 per cent. of cases, neurosyphilis? There were other problems awaiting solution. He had never been able to discover why syphilitic Parkinsonism was so rebellious to treatment; he had never seen a case which improved under treatment, yet syphilis of other parts of the nervous system did improve very greatly indeed. He had never seen a case of syphilitic amyotrophy in a child. Another peculiarity was the non-occurrence of central scotoma in syphilitic optic atrophy. It was difficult to understand the relation of symptoms to lesions in many cases of neurosyphilis; this was notoriously true of general paralysis of the insane. Finally, with regard to treatment, he exhibited the mortality tables for two main varieties of neurosyphilis over the last twenty years, and showed that the mortality from general paralysis had been halved while that from tabes had remained undiminished.

Mr. J. E. R. McDONAGH said that the inference he had drawn from the clinical and research work he had done on this subject was that all matters relating to syphilis must remain unsettled pending a resifting of the knowledge acquired since 1905. Serological tests were crude and non-specific, and could not be used as indicators either of the presence or absence of the infected phase, and the treatment, equally non-specific, did no more than correct the physical changes. The acceptance of the protozoa as having a complicated life-cycle which had to be completed before signs and symptoms manifested themselves explained the long incubation period, and why the word "cure" should never be used. In quiescent cases the spore could not be detected, but its presence in the body appeared to be lifelong, because a patient who had once had syphilis never became reinfected. The whole behaviour of the micro-organism in the body was determined by the state in which the host's resistance happened to be at the onset of and throughout the infection. It was the body, not the parasite, which varied. Hence it was incorrect to speak of neurotropic and dermatropic types of infection. Syphilis, by changing the blood in the way it did, was particularly apt to precipitate manifestations of disease and aggravate other diseases which had an ageing tendency. Experience had taught him that infinitely more was to be gained by treating the patient than by treating his infection. He was convinced that if syphilis and all other invaders were removed from their pigeon-holes, collected together, and regarded as a single cause of extrinsic disease, an enormous advance would be made. In short, there was nothing in syphilis, *qua* syphilis, different from any other invader.

Dr. BUCKLEY SHARP confined his remarks to treatment. The problem was to penetrate what had been called the "blood-brain barrier." Recourse had to be made to chemotherapy aided by the ability of the patient to defend himself against infection by his own immunity response. Chemotherapy was not just a simple process involving direct action of the drug upon the organism, like the action of an antiseptic; some other substance, unidentified, was formed by the interaction between the injected drug and the patient's tissues. Should intensive treatment be started at the earliest stage or should time be allowed for the development of the patient's own immunity response before active therapy was begun? In practice it was usual to commence treatment immediately after diagnosis. He believed that neurosyphilis was most likely to follow in cases inadequately treated at the beginning. What drugs could most readily penetrate the nervous system? The trivalent arseno-compounds in general use did not normally pass the "blood-brain barrier." Tryparsamide appeared to have a special affinity for the central nerve cells, and this drug was of great value in general paralysis. It had little if any effect on the somatic as compared with the neurological manifestations of syphilis. From a clinical point of view the most troublesome problem was that of tabes in its early stages. He knew of no medical treatment that would with certainty put an end to root pains and crises. He had tried malarial therapy in two cases of lightning pains, with only temporary benefit.

Dr. D. NABARRO spoke particularly of congenital syphilis as seen at the Great Ormond Street Hospital. One problem was why white children were ten times as susceptible as coloured. He had examined the cerebro-spinal fluids of 107 infants with congenital syphilis, and in no fewer than fifty-seven the fluid was abnormal. The figure indicated how frequently the central nervous system was invaded in congenital syphilis, yet very often lumbar puncture was not done. In infants, insufficient early treatment, particularly with mercury, might lead to recurrence of neurosyphilis in the second or third year. Neurosyphilis in children past the age of infancy might be latent or manifest, the former state being diagnosable only by lumbar puncture in all cases. In these cases disorders of conduct, fits of temper, moral obliquity, varying degrees of feeble-mindedness, and occasionally mental precocity, were encountered. Cases of juvenile tabes were very rare. He could recall only two during his twenty years at Great Ormond Street; one of them did very well on intravenous sodium iodide in association with arsenic, but the other on the same treatment showed no improvement. He gave details of an investigation of thirty-one families in which syphilis was probably or undoubtedly present in the third generation; in nearly every one of these cases the disease was transmitted to the third generation by an untreated congenitally syphilitic mother. It was frequently the second child who was most markedly affected.

Dr. W. NICOL described the work on malarial therapy at Horton Mental Hospital. Since 1925 just over 600 cases had been treated; at present some 200 cases were in the hospital. Nearly all the cases that would ever be discharged were ready for discharge in from seven to nine months. Omitting these recent cases, there were eighty-four women and fifty-three men now in hospital who had been under treatment for long periods: twelve of the women and seventeen of the men had shown improvement and were useful workers in the hospital, though not able to return to the outside world; others were deteriorating after some years of improvement. Malarial therapy indisputably prolonged the life of the general paralytic, and physical health improved. Why did some cases resist treatment and others not? Some might be explained by treatment beginning too late, but there were cases in which that would not hold. If a case did not respond favourably to a first course of malaria it was not likely to respond at all.

Dr. K. PADDLE said that his experience was limited to cases among mental defectives. The relation of syphilis to mental deficiency was even now not settled. In mental

defectives suffering from congenital syphilis was it to be inferred that the deficiency was the result of syphilis, or was it a coincidence? The family history of forty-seven unrelated cases of mental deficiency complicated by congenital syphilis revealed that in 50 per cent. there was a definite neuropathic agent, so that probably the mental defect was the result of the two factors acting together, when either might have been insufficient in itself to produce the condition.

Dr. L. C. COOK described his work at the Fountain Hospital, and divided patients of this character into two categories—those with abnormal and those with normal cerebro-spinal fluid. Of the latter he found it extremely difficult to say that their cases could be labelled neurosyphilis. The value of a cerebro-spinal fluid picture in congenital syphilis, whether as a guide to diagnosis, prognosis, or treatment, was to be doubted. A large percentage of the congenital cases had changes in the cerebro-spinal fluid, but he was doubtful whether any prognostic significance could be attached to such findings. It had struck him that the syphilitic patients tended to exhibit a greater emotional facility than other aments.

Mr. LINDSAY REA discussed some ophthalmological findings, and said that he had never seen a central scotoma in any syphilitic case. Dr. Kinnier Wilson had stated that probably the spirochaete was aided and abetted by some other organism. The speaker had come to the conclusion that a gonorrhoeal iritis occurred only in people with some form of dental sepsis, and that the two conditions were definitely related. He was sure that many of these diseases were not due to one specific organism.

Mr. SYDNEY SCOTT spoke from the point of view of the otologist, and said that it was extremely difficult to diagnose clinically, from any special examination, whether a patient had a syphilitic lesion of the vestibular or cochlear nerve, though he had seen syphilis of both these nerves. He showed a number of lantern slides to illustrate the difficulties of otological investigation in this field. Dr. HUGH GARLAND said that although he believed in treatment with bismuth and N.A.B., there were certainly cases which did develop neurological signs despite such treatment. Dr. FERGUS FERGUSON asked whether in a case of early tabes dorsalis one was justified in advocating malarial treatment in view of its risks. Was the treatment to be justified in the case of a young person? Dr. LEONARD FINDLAY had had the opportunity of treating some seven cases with malaria and found no disadvantage; one case, apparently, was cured, and in another the disease was arrested. On the other hand, he had not seen the least benefit from treating neurosyphilis with mercury or salvarsan. Mr. LESLIE PAXON said that he knew of only one reported case of central scotoma in neurosyphilis. He thought that he himself had discovered one case, in a tabetic who had been coming to Queen Square for thirty years; it was certainly a central scotoma, but further investigation proved that it was due to tobacco, not to tabes. He gave an anatomical explanation for the rarity of central scotoma in these conditions. He also stated that he had seen one undoubted case of reinfection with syphilis.

Dr. KINNIER WILSON, in closing the meeting, remarked that most of the questions he had posed at the beginning remained still unanswered.

PROBLEMS IN THE STUDY OF SCIATICA

At the meeting of the Section of Physical Medicine of the Royal Society of Medicine on October 19th Dr. J. BARNES BURT, the president, instead of reading a presidential address, opened a discussion on some problems in the study of sciatica.

Dr. Burt first posed the problem of classification. A practical method was to divide sciatica into three main clinical groups—namely, (1) root sciatica, (2) trunk sciatica, (3) referred sciatica. This classification was also an anatomical one if the word "branch" were substituted for "referred," and formed a definite basis for diagnosis and treatment. It was often said that referred sciatica

was not true sciatica; but it was certainly true "leg ache," and the pain was distributed along the branches of the sciatic nerve. Many used the terms "primary" and "secondary"; the term "true" was also used; but Dr. Burt urged that these terms should be abandoned. Putti, the Italian orthopaedic surgeon, had written the classical article on root sciatica, and had proved that it was a clinical entity, though his definition of "root" was slightly different from that usually adopted in this country. Dr. Burt had analysed his figures at Devonshire Hospital, Buxton, and had found that out of 140 cases 35.5 per cent. were of root sciatica, 17 per cent. of trunk sciatica, and 45.5 per cent. of referred sciatica. It followed that the average medical student learned his sciatica on the rarest type, while referred sciatica was lost in the mass of differential diagnosis. Dr. Burt claimed for his own classification that the groups were quite distinct: in most cases the diseases were entirely different, with different pathology, onset, and treatment.

The second problem he put to the meeting concerned differential diagnosis. Generally speaking, the symptoms of referred sciatica were less severe than those of sciatica belonging to the other groups. The pain was seldom constant, and often did not reach below the ankle. Sensory signs were absent, and although there might be some muscle wasting this was of the general type, due to disuse. Unfortunately, similar mild symptoms might occur in a mild case of root sciatica. It was a mistake to think that root sciatica produced more serious symptoms than trunk sciatica or referred sciatica. Putti regarded rigidity of the lumbar spine as a constant sign in root sciatica: there were two other signs which, although not constant, assisted the diagnosis—namely, tenderness along the lateral aspect of the lumbar vertebrae and distribution of pain along the external cutaneous nerve of the leg. This was not a constant sign, but when it did appear it put one on the track at once.

Dr. Burt's third problem related to the varieties of referred sciatica. Every textbook was full of sciatica caused by osteo-arthritis of the hip. To his mind this was a cause very much exaggerated. The only two cases out of the 140 which he had analysed having severe sciatica associated with osteo-arthritis of the hip were also cases of osteo-arthritis of the spine. Sciatica due to sacro-iliac disease was simply bristling with problems. A number of people had suggested that inflammation spread by direct contact from the sacro-iliac joint into the roots of the sacral plexus. This had been very carefully investigated. If there was swelling of the intervertebral joint it would press the nerve right against the opposite side of the bone, and in many cases the inflammation spread into the tissues in that way: thereby a root sciatica might become a trunk sciatica, the inflammation spreading down the roots into the trunk. It was a problem to him why sciatic pains were not found in spondylitis deformans. In practically every such case there was ankylosis of the sacro-iliac joint, and one would have thought that inflammation severe enough to produce ankylosis would be sufficient to give rise to sciatica. The most interesting of the referred sciaticas was that due to fibrositis of the gluteus medius and minimus, partly because it was not mentioned in the textbooks, and partly because it was easily cured if correctly treated. If one slipped on a rug or a parquet floor pain was felt just over the gluteus medius muscle, and one was likely to have a certain amount of sciatica. In driving a car with a seat that did not suit the leg a certain amount of sciatica was apt to develop by reason of strain on the gluteus medius. The greater part of these muscles was lying on the bone, and was covered by one of the firmest aponeuroses in the body. A branch of the superior gluteal nerve travelled along the surface of the ilium to supply the muscles. Any inflammatory swelling of the muscle in this confined space set up a pressure on the nerve, or possibly the nerve was involved in the inflammation, and the pain was referred to areas of the leg supplied by the fourth and fifth lumbar, chiefly the peroneal branch of the sciatic nerve. All these cases of sciatica got well quickly. Another problem concerned Lasègue's sign, the value of which was belittled by both Putti and Buckley. The sign was not of

pathognomonic value: it occurred only in two conditions—namely, trunk sciatica and the sacro-iliac condition. Two modifications of the sign might prove exceedingly useful. One was Dr. Mennell's modification, in which, as the leg was raised with the knee straight, the foot was extended or flexed; with the foot extended it could be raised a little higher in sacro-iliac trouble than in trunk sciatica. The other was what he called the "floor sign," in which the patient sat flat on the floor with his back against a wall. The back of the knee normally touched the floor unless he had arthritis (or acute trunk sciatica, in which case he could not sit down in that manner at all): the positive sign only appeared if there were adhesions. Out of his 140 cases only nine had a positive "floor sign."

Finally, Dr. Burt touched on the subject of treatment. Massage was of value in two classes of conditions. In the case of referred sciatica due to fibrositis of the gluteus medius early massage would effect a cure. If, however, the condition was not treated properly, and the unfortunate patient "worked it off," the inflammation spread to the fascia of the gluteus maximus and into the trunk sciatic nerve. The other condition that benefited by massage was sacro-iliac trouble. But massage must be given by careful prescription—gluteal muscles only, and bed for an hour afterwards.

DISCUSSION

Dr. WILFRID EDGEcombe said that Dr. Burt's percentage of 45 as coming within the "referred" group related to hospital cases. In private practice the proportion of these cases was much greater—perhaps 65 or 70 per cent. The cases were easily curable: in the acute stage nothing but rest, heat, and large doses of aspirin; later, intelligent massage. More troublesome cases were those of acute toxic neuritis of the sciatic nerve: the pain was severe and constant, irrespective of movement, and the wasting of muscles was marked and dramatic. Dr. C. W. BUCKLEY asked whether it was true that pressure on a nerve fibre produced pain. Pressure produced first "pins and needles," then numbness of the parts affected, and, if a motor nerve was involved, muscular wasting; but it did not create pain. If there was pain it was due to pressure on that specialized organ, the nerve-end. Dr. A. R. NELIGAN drew attention to a form of sciatica which seemed to be connected with varicose veins in the leg, and to clear up when the veins were treated. As to massage in sciatica, one form which he had found extremely useful was the underwater douche. Dr. W. J. TURRELL related particulars of some cases of the radicular type, and Dr. ALASTAIR MACGREGOR referred to the value of mild faradic current in locating tender points in trunk sciatica.

AWARENESS IN PSYCHOLOGICAL MEDICINE

An extraordinary general meeting of the Medical Society of Individual Psychology was held at 11, Chandos Street, W.1, on October 11th, Dr. J. C. YOUNG being in the chair. The objects of the society were defined more exactly in the following resolution, which was adopted:

The objects of the society shall be: (1) to advocate and extend the general psychological approach to medicine, and (2) to promote the study and discussion of individual psychology. Membership shall neither require nor imply formal adherence to any particular school of psychology.

The chairman inaugurated the session by an address on "Awareness in Psychological Medicine," in which he said that the consciousness of the higher animals differed from the consciousness of the human animal in that the latter, in addition to the vital or organic memory common to both, disposed of a voluntary capacity for recollection not found in the other animals, notwithstanding, for example, the elephant's long memory for kindnesses and injuries. This recollection was a function of vital memory rather than voluntary recollection. Nevertheless, in so far as human voluntary recollection consisted in the last resort in the capacity to delay and to co-ordinate reflexes, depending somatically on a highly differentiated nervous organization of highly differentiated parts, the difference

between human and animal consciousness might be said to be only one of degree. There was no essential difference in kind. Similarly there were differences, as between man and man, in degree of human consciousness, almost amounting to a difference in kind. The higher degrees of consciousness implied higher degrees of integration with less liability to the disintegration or dissociation which was the essential feature in neurosis and psychosis. Dr. Young thought it useful to designate these higher degrees as "awareness." No sharp dividing line could, however, be drawn between awareness and consciousness. But awareness connoted a degree of self-awareness of motive and life goal which was deficient in the neurotic and practically extinguished in the psychotic. Awareness did not happen mechanically, nor could it be achieved by mechanical reading of textbooks. It required work on oneself and a certain disciplinary sincerity. Only in virtue of awareness born of experience recognized in himself of the psychological realities and mechanisms which had overwhelmed his patients could the physician in psychological medicine hope to cure or alleviate their sufferings of unawareness of dissociation and disintegration.

ADHESIONS IN ARTIFICIAL PNEUMOTHORAX

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, held on October 5th, Dr. GUSTAV MAURER, medical superintendent of the Sanatorium Guardaval, Davos, read a paper on a modification of the Jacobaeus operation for pleural adhesions in cases of artificial pneumothorax.

Dr. Maurer described the technique of his method for the examination and delimitation of adhesions with a thoracoscope, their transillumination with an instrument of his own design, and their enucleation from the chest wall. The advantages of this method were absence of shock and a great reduction in the incidence of post-operative complications, such as empyema, haemorrhage, and pleural effusion. More than eight hundred cases had been operated upon, with a mortality of less than 1/2 per cent. The paper was illustrated by lantern slides and x-ray plates.

The President of the Academy (Mr. R. A. STONEY) said that there was no doubt that the surgical treatment of tuberculosis was still in an adolescent stage in Ireland, and that no general attempt had been made to undertake surgical treatment as an aid to the management of cases of tuberculosis of the lungs. In connexion with the surgical treatment of tuberculosis the team spirit—the close co-operation of physician, surgeon, and radiologist—was most important. Every case should be carefully considered on its own merits, and no rule-of-thumb methods should be adopted. He believed that there was a great field open before the surgical side of the medical profession in regard to the treatment of tuberculous cases. The work was extremely technical, and the results obtained by Dr. Maurer, the x-ray photographs, and the description of the cases seemed to him almost miraculous. There was no doubt that this was, and always would be, work which required extreme knowledge, experience, and delicacy of technique. He would like to recommend to the younger generation of surgeons this large field of surgery in which they could exercise and develop their talents.

Dr. HAROLD QUINLAN said that in the out-patient department of the hospital to which he was attached he saw from 120 to 150 cases of pulmonary tuberculosis a year. Of these, about 66 per cent. were unilateral, and on that account a great number of them were suitable for pneumothorax. He had seen some cases in which adhesions had been cut, but thought that it was very difficult to find cases which were really suitable for this procedure. In some cases excellent results were obtained by thoracoplasty. He personally did not like interfering with adhesions unless they were very thin and fibrous in character.

Dr. W. R. F. COLLIS felt that this was a line of treatment, really more medical than surgical, which might be more widely adopted.

Dr. J. B. MAGENNIS confessed himself amazed to hear of the very successful results obtained by Dr. Maurer by the operation he described in cases which the majority of medical men would have looked upon as hopeless. Referring to the value of internal transillumination of adhesions, he said that, until one had interfered with an adhesion without knowing it, it was impossible to realize the importance of transillumination. He was interested to note that in Dr. Maurer's cases there had been so little reaction on the part of the pleura. He felt that the failure to make advances in the treatment of tuberculosis as rapidly in Ireland as in other countries was largely because there was no central hospital for tuberculosis. Many hospitals tried to keep a small ward only for tuberculous patients, but if there was one hospital only for tuberculous cases treatment would be much easier.

Dr. LEONARD ABRAHAMSON stressed the need for more adequate accommodation for tuberculous patients, and for better equipment and facilities in the existing institutions. He thought that small general hospitals were unsuited to the treatment of such cases. In regard to operative procedures, whilst definite advance had been made of late years, a little conservatism was indicated in contemplating such measures in a given case. Dr. A. R. PARSONS said that until he had heard Dr. Maurer's paper he had had very little faith in the procedure of division of adhesions, as he thought it was an extremely difficult operation, and one which was attended with great risk to the patient. Since hearing Dr. Maurer he had changed his opinion. Dr. Maurer had operated on 815 patients, and of these only three had died as a result of the operation—a mortality of less than 1/2 per cent. He considered this an amazing result for surgery, and he would like to congratulate Dr. Maurer on the extraordinary results he had obtained.

The President of the Section (Dr. V. M. SYNGE), in complimenting Dr. Maurer on his work, said that in some cases the cures were little short of miraculous. He was interested to notice the very small number of cases in which an exudate had occurred, and thought that this was very significant.

CHOLESTEROL AND DISEASE

At a meeting of the Pathological Society of Manchester, held on October 10th, Professor S. L. BAKER delivered his presidential address on "Cholesterol and Disease."

Cholesterol deposits, he said, might be either generalized, when they were of metabolic origin, or local, following local destruction of tissue. Arterial disease was the most important condition in which cholesterol deposits were found, and had been much studied experimentally. Several distinct processes were concerned in the production of the common forms of arterial hardening comprised by the term "arteriosclerosis." Of these processes the most important was atherosclerosis, characterized by the development of fatty (lipoid) streaks and patches and atheromatous deposits, particularly in the aorta and its main branches. Rabbits whose diet contained powdered cholesterol showed such lesions. Their development was due to the greatly raised blood cholesterol. The lesions were closely similar, both topographically and histologically, to those seen in human atherosclerosis. The type of lesion depended on the time the rabbits were allowed to survive. Fatty streaks and patches were early lesions, while raised patches with intimal fibrosis occurred later. Spontaneous atherosclerosis was very rare in the rabbit, but in man it was present in some degree in almost all subjects. The fatty (lipoid) streaks seen in children had been regarded as toxic effects, but it had been found that their incidence was correlated with age, and not with toxic conditions. It was probable that the slighter lipid deposits might disappear, but deposits tended to increase with age.

In diabetes and the nephrotic type of renal disease, conditions in which hypercholesterolaemia was present, there was an increased tendency to atherosclerosis. There was no evidence that hypercholesterolaemia led to hypertension, but increased strain on the arterial wall predisposed

to lipid deposits. Extensive atherosclerosis might be found in subjects not showing hypercholesterolaemia, but work on rabbits had shown that atheromatous deposits following a temporary rise in blood cholesterol remained in the arterial walls for long periods. The experimental evidence incriminating cholesterol in the production of atherosclerosis was abundant, but much further systematic work on the fluctuations of blood cholesterol in the human subject was needed to throw more light on the problem.

The address was copiously illustrated by Professor Baker's own preparations.

CORRESPONDENCE

Trauma and Pulmonary Disease

SIR,—The annotation on chest injuries and pulmonary tuberculosis in the *Journal* of October 13th (p. 689) emphasized once more the necessity of thorough inquiries into the immediate and remote results of chest injuries, and into the mechanics of the production of such extreme lung damage as recorded by Dr. E. G. Fenton in the same issue (p. 700), and lesions of lesser degree.

The inquiries might begin with the pooling of cases of trauma in connexion with pneumonia, empyema, haemoptysis, pneumothorax, and haemothorax, and cases of pulmonary tuberculosis directly caused or aggravated by injury. Physicians and pathologists to large hospitals and tuberculosis sanatoria, and many general practitioners, must have records of such cases. The criteria to be satisfied as to the association between trauma and subsequent disease might be considered by such a body as the Science Committee of the British Medical Association. A discussion on the mechanics by a body of physicists detailing their experiments would be not only a mental entertainment but of real assistance in visualizing the various degrees of lung disruption.

The results would be of considerable academic interest and of very great practical importance. Problems of diagnosis, treatment, and prognosis in the various conditions would be ventilated, and groups of definite cases placed on record which would be invaluable in workmen's compensation and medico-legal practice as well as in general medicine.

If the Science Committee could be prevailed upon to undertake the work I feel sure the members would have the cordial co-operation of all branches of the profession. —I am, etc.,

Wigan, Oct. 19th.

W. E. COOKE.

B.C.G. Vaccine

SIR,—In his recently published book *The B.C.G. Vaccine* Dr. K. Neville Irvine recommends (p. 62) the administration of 0.1 mg. of B.C.G. vaccine intradermally, and adds that the vaccine may be obtained free from the Institut Pasteur, Paris, by asking for "parenteral B.C.G."

The Pasteur Institute supplies three varieties of ampoules at present: (a) BCG, for oral vaccination soon after birth, containing 1 cg. of bacilli in 2 c.cm.; (b) BCG-NR, for oral vaccination in children older than 2 years and in adults, containing 5 cg. in 10 c.cm.; and (c) BCG-SC, for subcutaneous injection (the Pasteur Institute does not recommend the intradermal method), containing 1/50 mg. in 2 c.cm. To obtain a dose of 0.1 mg. one would therefore have to use 0.02 c.cm. of ampoule (a) or (b), or 10 c.cm. of ampoules (c). Clearly both of these alternatives would be impracticable.

Dr. Irvine must therefore have in mind B.C.G. emulsions prepared elsewhere. With those supplied by the Institut Pasteur, Paris, either a different dose or a different dose and another route than those he indicates

would have to be adopted. Incidentally, Dr. Irvine does not mention in his recommendation the fact that the vaccine must be used not later than ten days after its preparation—the earlier the better—a point well worth remembering in obtaining the vaccine from Paris.—I am, etc.,

Vejlsted Sanatorium,
Denmark, Oct. 13th.

G. GREGORY KAYNE.

* A review of Dr. Neville Irvine's book appears this week at page 773.—Ed., B.M.J.

Pre-natal Cardiac Murmurs

SIR,—The letter from Dr. A. W. Johns (October 20th, p. 743), concerning a case of congenital heart disease diagnosed before birth, reminds me of a question that has long simmered in the back of my mind. I have had in the past certainly two cases—and I rather think three, but am not quite sure—in which I have found a cardiac murmur in the auscultated heart-beat of a foetus *in utero*; and in each case I confirmed the observation by repeated examinations. In none of the cases was there found any abnormality about the cardiac sounds of the newborn infants. The point I have long pondered is this. If the foramen ovale is patent in the unborn child, and the circulation passes through it, and if patency of the foramen ovale after birth causes a cardiac murmur, why does not every foetal heart-beat exhibit, on pre-natal auscultation, a murmur likewise?—I am, etc.,

Woolton Hill, nr. Newbury,
Oct. 20th.

HENRY ROBINSON.

Motor Backache and Neuralgia

SIR,—Some of your readers may perhaps be personally interested in a rather common form of postural strain, which may arise as the result of motor-driving from an inefficient seat over a prolonged period. In its milder grades this seems to be a widely prevalent source of discomfort, but the severer and more important forms are likely to be indifferently confused with such conditions as lumbago, rheumatism, and sciatica from other causes, and their origin lost sight of. The distinction is an important one from the aspects of prevention and possibly of treatment.

I must ask to be excused for quoting in detail my personal experience as a patient, but such description seems to afford explanation of the cause and of the symptoms which arise from this particular strain.

Rather more than six months ago I developed an unpleasant pain in the left buttock and across the lower part of the back, and early recognized that this was induced by motoring. It was accentuated by any attempt to flex the spine in the lower dorsi-lumbar region. Lateral, rotatory, and extension movements were quite free and painless, but flexion speedily became greatly affected. It was no longer possible to get near one's toes, and as time went on putting on shoes and socks became a painful difficulty. There was much other difficulty of a similar kind, although it was at this time possible to lead an active life in some ways hardly to have been expected. For example, it was possible to play tennis with comparative comfort, but then necessary to flex the right knee and get down with a stiff left leg when attempting to pick up a ball.

Such mild exercise and walking tended to lessen temporarily both pain and stiffness; later they might be accentuated. Standing and lying prone were both more comfortable than sitting, which on a hard chair was quite intolerable. Commonly, I took my meals standing, and wrote my letters lying on my face. At this time there were no descending leg pains.

It seemed possible that insufficient exercise, by reducing muscle tone, had contributed towards this disability, but this factor was recognized too late. A period of deliberately active holiday (in which, notably, swimming in sea water was easy

and completely free from pain) was followed by an increase of symptoms—distressing neuralgic pains in the course of the left sciatic nerve, reaching to the foot, and about the buttock to the level of the iliac crest in the region of the left anterior superior spine, and beside the sacrum and coccyx. Travelling in all forms had become most painful; particularly any vibration greatly added to pain. I have been reduced to sitting on the floor in a taxi, in order to get some relief from the support of the seat edge. Walking was reduced to a limp and, crippled to this extent, work had to be abandoned.

There was much stiffness of the lower part of the spine, and x-ray examination showed no obvious disease. Rectal and urinary examinations and lumbar puncture were normal.

Much earlier I had come to the conclusion that the cause of the condition was the inefficient disposition and form of the driving seat in my car. Many observations supported this conclusion—in early days the creation of a backache whenever I used it; later, the degree of relief which could be obtained from a properly placed air cushion, low down behind the right side of the sacrum. By inquiry from others—motoring friends and garage owners—I learned how commonly varying degrees of discomfort were complained of.

The driving seat of the car, looked at after the event, appears to be particularly designed to give trouble. It is of the "bucket" type, fitted with air cushions but with back and seat heavily raked so as to present the shape of the letter L tipped backwards. Such an arrangement necessarily creates an unoccupied angle, resulting in inadequate support to the dorsi-lumbar region of the driver. Such a single-bucket seat is subject to much enhanced vibrations, which no doubt increase the strain thrown on ligaments when muscles become fatigued: vertebrae then tend to sag and stretch the posterior aspects of the intervertebral joints.

Clearly it might be expected, as it was experienced, that flexion of the lower spine would give the maximum of pain. Exactly how pressure comes to bear on spinal roots and give rise to neuralgic pain is a matter for conjecture, but it is not surprising that it should so happen, and it may be due to local oedema and subsequent adhesion.—I am, etc.,

London, W., Oct. 21st.

G. H. A.

Residual Infection of the Jaws

SIR,—Mr. Nodine's letter that appeared in the *British Medical Journal* of October 20th raises a number of very important points for consideration. It is undoubtedly true that the condition of residual infection of the jaw would almost be non-existent if the Novitsky technique was employed more generally, but until the dental profession is educated to the standard of Novitsky and his successors residual infection of the jaw will occur, and the clinical manifestations will be observed. Mr. Nodine has done a great service in calling attention to the possibility of preventing residual infection; he was the first person to introduce the Novitsky method into this country, and the profession owes a great debt of gratitude to him.—I am, etc.,

London, W.1, Oct. 19th.

R. S. TAYLOR.

Ether Convulsions

SIR,—I have read with interest Dr. Stanley Sykes's letter on the subject of ether convulsions, and would like to confirm his findings.

A child, aged 6, was being anaesthetized for tonsillectomy with ether vapour from a Shipway apparatus, the head being extended by a sandbag under the shoulders. After fifteen minutes anaesthesia convulsions were seen to commence in the leg muscles, and rapidly spread all over the body, the face being affected last. The operation was stopped and the anaesthetic discontinued, but the convulsions increased.

Eventually the head was raised through a right angle and the convulsions ceased immediately, and did not recur when the head was lowered a few minutes later. The operation was then completed and recovery was uneventful.

In this case the head was lower than the rest of the body, and the cerebral anaemia produced by raising it was almost certainly responsible for the cessation of the convulsions.—I am, etc.,

London, N.W.3, Oct. 22nd.

C. J. M. DAWKINS.

Death and the Survival of Rights of Action

SIR,—I think, with respect, that the learned author of your article under this heading, published on September 29th (p. 600), and Dr. Hugh Woods, who contributed a letter to your correspondence columns on October 6th (p. 658), much exaggerate the danger to the medical profession of the Law Reform (Miscellaneous Provisions) Act, 1934. Your leader-writer suggests that a surgeon whose patient dies on the operating table is open for six years to an action for negligence by the personal representatives (that is, the executors or administrators of the deceased's estate). This may, technically speaking, be true, but the practical risk is surely very remote. The Act specially provides that where personal representatives are suing for the benefit of a dead person's estate the damages must not be exemplary, and, when the death has been caused by the negligence, they must be calculated without reference to any loss or gain to his estate consequent on his death, except that a sum in respect of funeral expenses may be included.

In face of these limitations it is difficult to see quite what damages the personal representative can claim. The learned writer of a leading article in the *Lancet* (1934, i, 1177), so far from foreseeing damage to doctors from this source, protests that personal representatives will not even be able to claim the expenses of the hospitalization and treatment of the deceased, so that doctors and hospitals will once more go uncompensated. The widow and children can, of course, claim damages under the Fatal Accidents Act, 1846; they have been able to do so for nearly ninety years, but the harm done thereby to the medical profession has been negligible. Truly, they have only a year to make their claim, and the personal representatives have the six years allowed by the Statute of Limitations, but the personal representatives are so little likely to succeed in a stale action that few in all probability will make the attempt.

Your leader-writer's second hypothetical case, where a patient whose treatment has gone wrong subsequently dies for some other reason, has more substance, for here the negligence, if any, has not caused the death, and it seems that the personal representative may claim damages for injury to the estate due to such factors as the deceased's inability to earn and the expense of his later treatment and convalescence. But they would have to explain why the deceased had not thought it worth while to bring an action: they would be deprived of his evidence, and although they might prove the injury to the estate they would probably find such difficulty in proving it due to negligence that they would think very long and carefully before they ventured to go to court. "Londoner," in the *Evening Standard*, suggested recently in his Diary an even more fantastic case: that if a legacy of £500 had been left to an individual but on examination the estate was found to be insolvent, the legatee could then bring an action for damages against the doctor. It is sufficient to remark that this suggestion entirely neglects the provisions of the Act which I have quoted, and, in addition, at least three elementary rules of common law. The *Law Journal* (October 6th, p. 206) has dealt with it far more crushingly than I could.

The plain truth is that the Act was passed with one particular purpose in view. The Common Law contains a peculiar doctrine that the right of personal action dies with the person. The result was that when a negligent motorist injured someone and was himself killed in the accident the injured party had no redress. He could not sue the estate, and he could not even recover from the negligent one's insurance company. The Act sets right an intolerable injustice. It is a principle of law to give the same rights to both sides, and so the Act allows the personal representatives of an injured person who has died to sue in his place, but has very closely limited their right to damages—so much so that negligence actions by personal representatives are likely to be few and far between.

It is always possible to construct theories from legal doctrines and enactments, just as it is from philosophical premisses, but such inventions commonly have little if any relation to practical affairs. They are unfortunate when they tend to frighten unnecessarily a body of deserving persons who already have to face more than their share of real legal danger.—I am, etc.,

London, E.C., Oct. 23rd.

D. HARCOURT KITCHIN.

Publicity

SIR,—As one who has received a large amount of publicity in the lay press, may I say that so far as I know I have never been one penny the richer on account of it so far as my medical practice is concerned. I fully agree with Dr. Frank G. Layton that we are all guilty in one way or another of seeking publicity, and that, so long as a man does not profess to have some special treatment which he alone is capable of administering, it is all completely harmless.

Let us clear our minds of cant on this topic. Every article in the *B.M.J.* is an advertisement, intended to be read by the profession. These articles, and the personal recommendation of satisfied patients, are the only form of publicity that is likely to increase our incomes. Yet the *B.M.J.* is read by thousands of lay men and women throughout the country. It is one of the most popular journals in the free libraries, and anyone who has ever visited these public reading-rooms must have noticed old ladies poring over your columns for hours. If the *Journal* is only intended for the profession, why allow it to be circulated in free libraries? But for the old ladies many of us, by using the free libraries, might save our subscription to the Association; and if the old ladies are allowed to read the *B.M.J.*, what possible objection can there be to the newspapers selecting from your columns any matter that they consider to be of general interest to their readers?—I am, etc.,

London, W.8, Oct. 19th.

HALLIDAY SUTHERLAND.

* * However much some medical men might wish us to do so, we cannot control the newspapers or the public libraries or the old ladies.—Ed., *B.M.J.*

Whither General Practice?

SIR,—I would like to thank Dr. W. Savile Henderson for his letter in the *Journal* of October 20th (p. 742) and for ventilating what, I think, is a very general abuse. I may say that I have had an almost identical experience with the one he describes in Case 1, and, like him, received the same reply when I complained to the authorities. I have also had complaints from patients about welfare workers trying to force their way into the house to give advice on a variety of medical subjects without my knowledge or consent, and have been asked, indignantly, if I had sent them. This state of affairs

causes a loss of confidence between the family doctor and his patients.

I would like to suggest that the authorities should issue a strongly worded standing order to all welfare workers, that they must call on the doctor *before* they visit any of his patients, and discuss the case with him first. I have never had the courtesy of a visit from the welfare worker.—I am, etc.,

RUPERT PALMER, M.R.C.S., L.R.C.P.

Lydd, Kent, Oct. 21st.

SIR,—We must all sympathize with Dr. Savile Henderson in his discovery that not only lower-class but also middle-class patients are being inveigled away from the general practitioner to the public clinic, and in his plea for a remedy.

If Dr. Henderson read the report of the discussion at the Annual Representative Meeting at Dublin last year (*Supplement*, August 5th, 1933, p. 86) he will remember that it was stated there (by a member of Council) that infant welfare was educational work, and could not be done in general practice. So if Dr. Henderson accepts this view he will sit down and rejoice that the work which a mere general practitioner was unwisely attempting is being taken into the hands of people more competent to perform it.

If, on the other hand, as appears from his letter, Dr. Henderson does not adhere to this mediaeval theory, then he may accept my suggestion (*Supplement*, July 14th, 1934, p. 33) that the general practitioner is actually the person in the best position to undertake infant welfare, and let his patients know that he is able and willing to give them all that the public clinics can offer them as regards infant welfare. If he does, then I am sure that he need not fear the competition of the local authority.—I am, etc.,

London, S.W., Oct. 22nd.

F. GRAY.

Correction of "Medical Register"

SIR,—I am desired by the Returning Officer to say that voting papers for the purpose of the forthcoming election of a direct representative to the General Medical Council were issued on October 23rd to all registered medical practitioners having registered addresses in England and Wales; and that the authorities of the Council would be glad if every such practitioner who has not received a voting paper would communicate immediately with the Office of the Council (44, Hallam Street, London, W.1), whether or not he proposes to vote in the election, in order to ascertain that his address is correctly entered in the *Medical Register*.—I am, etc.,

MICHAEL HESELTINE,
Registrar, General Medical Council.

October 24th.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on October 18th the following medical degree was conferred:

B.M.—G. H. Buck, J. P. Dewsbury, C. M. Vaillant, A. B. Stokes.

UNIVERSITY OF CAMBRIDGE

The Vice-Chancellor announces that Sir Percival Horton-Smith Hartley, M.D., sometime Fellow of St. John's College, has conveyed to him through the good offices of the Regius Professor of Physic his desire to make over to the University, for the further endowment of the Raymond Horton-Smith Prize, securities producing an income of £20 a year. The foundation of this prize, for the best M.D. thesis in each academic year, is recorded on page 339 of the *Historical Register*. Sir Percival is the eldest son of the original donor and a brother of Raymond John Horton-Smith, whom the

prize commemorates. His gift would restore the former value of the prize, and would increase its value beyond the former amount if payment of dividends upon the present investments of the fund should be resumed.

At a congregation held on October 19th the following medical degree was conferred:

B.CHIR.—*M. A. Rugg-Gunn, *T. V. Tattersall, *A. R. R. Mears, G. T. Hindley.

*By proxy.

UNIVERSITY OF MANCHESTER

Dr. R. W. Fairbrother has been appointed lecturer in bacteriology, and Dr. J. C. Kerrin succeeds him as assistant director of the routine section of the Department of Bacteriology and Preventive Medicine. Dr. D. T. Robinson has been appointed assistant lecturer in bacteriology, and Dr. I. A. Cathie and Dr. James Dawson demonstrators in pathology.

UNIVERSITY OF WALES

The following candidates have satisfied the examiners in the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—(Part II): K. J. Grant, T. M. A. Lewis, J. C. R. Morgan, Elizabeth S. G. Owen, Jean J. Smith.

UNIVERSITY OF GLASGOW

A congregation was held on October 20th, when the following degrees were conferred:

M.D.—*W. S. L. McLeish, *C. Nicholson, Elizabeth J. Findlay, D. P. Leiper, J. Riddell.
M.B., Ch.B.—†R. C. Elitzik, †E. M. Rappaport, †J. D. O. Kerr, *M. Lazarowitz, *S. Smith, *H. Gillies, *J. H. Hutchison, *B. Joseph, *A. B. Semple, *C. L. Elder, *D. Gersten, *Gertrude I. R. Tannahill, *R. W. Carslaw, *R. McI. Millen, *C. Slutsky, *D. Ferguson, *J. D. Fulton, *D. Livingstone, *E. L. Nicolson, R. H. Adam, G. H. Aitken, Eleanor M. Alexander, W. J. Barclay, J. Black, R. Black, W. M. Borthwick, J. F. D. Boyd, D. B. Brown, J. Brown, G. G. Browning, J. N. M. Chalmers, Janet M. S. Clark, G. B. M. Clarke, N. P. R. Clyde, M. X. Colby, G. C. Cooper, J. E. Craik, J. F. Diamond, D. O. Dickie, D. Douglas, R. J. Eadie, Sarah G. Fee, I. Felsen, A. G. Fergusson, J. D. Finlayson, R. E. Fletcher, S. L. Frank, N. A. Freebairn, L. D. Gardner, Helen M. Gibb, G. C. Gordon, J. M. Graham, J. R. Hendry, Agnes B. Herbert, J. Hodge, J. Hughes, G. Hunter, A. Hutchison, J. S. Jackson, A. Leitch, M. Levinson, W. Love, A. D. Lynch, A. F. McDonald, J. Macdonald, J. A. MacDougall, J. S. L. McGibbon, Ethelwyn M. McKendrick, A. McKenzie, Roberta M. C. MacLean, J. Macrae, W. Mallinson, K. H. Martin, W. J. Moffat, R. Murdoch, J. J. Murray, J. Parker, Marion A. Pearson, R. Pettigrew, J. D. Ramsay, J. D. Rankin, J. L. Rankin, J. A. Rankin, J. G. Roberts, J. B. McN. Ranciman, Olive Scott, M. S. Segall, Ada M. Sewell, Helen S. C. Smith, N. Sragowitz, Jean W. * With commendation. † With honours.

R. C. Elitzik gained the Brunton Memorial Prize, awarded to the most distinguished graduate in medicine for the year 1934, and E. M. Rappaport gained the West of Scotland R.A.M.C. Memorial Prize, awarded to the candidate with the highest aggregate marks in medicine, surgery, and midwifery in the final M.B. and Ch.B. examination held during 1934.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Museum Demonstrations

The autumn course of museum demonstrations in the theatre of the College commenced on Monday, October 22nd, when Mr C. E. Shattock showed specimens illustrating bone tumours. To-day (Friday, October 26th) Dr. John Beattie discusses the functional anatomy of the pituitary gland, and on November 2nd and 9th respectively he will deal with dysfunction of the anterior lobe of the pituitary gland, and the posterior pituitary problem. On October 29th Mr. Cecil P. G. Wakeley will discuss tumours of the intestinal tract, and on November 5th Mr. E. K. Martin will show specimens illustrating surgical diseases of liver and bile ducts. All the demonstrations commence at 5 p.m.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh, held on October 16th, with Dr. A. H. H. Sinclair, president, in the chair, the following successful candidates were admitted as Fellows:

F. Bartholomew, B. W. F. Bi-hop, E. Bourke, J. J. M. Brown, A. J. Cameron, H. F. Cameron, J. E. Ellison, J. Gerrie, R. N. Ghosh, F. J. D. Gillespie, H. R. Goldberg, S. W. Grimwade, G. C. Halliday, R. W. G. Kelly, A. B. Kerr, W. D. Macfarlane, C. W. McVicar, A. M. Marshall, G. G. Mowat, D. N. Wilson, E. C. Wynne-Edwards.

Obituary

PROFESSOR RAMÓN Y CAJAL

Santiago Ramón y Cajal died on October 18th at the age of 82. To most medical men in England his name has been familiar since their study of histology, but few have realized the greatness of his achievements. Of these perhaps the chief is the stimulus which he gave to scientific education in Spain, and the advances in educational methods which were based on his advice. How much of his thoughts were given to this subject may be gleaned from any of his more personal writings. The prefaces to his books show a complete devotion to science and a desire for recognition, not of himself, but of Spanish science. He was, in fact, the father of Spanish science, for no Spaniard before him had made any noteworthy contribution to scientific knowledge.

Cajal was entirely self-taught. His father, who was professor of anatomy at Zaragoza, first turned his attention to the structure of the human body, and his intense love of beauty and skill in drawing stimulated his interest in histology. He owed to Golgi's publications and to photographic methods the use of silver impregnation in histological work. But apart from Golgi he had no teachers. His first medical excursion to foreign lands was to demonstrate his preparations of the nervous system to the German Society of Anatomists. His life-work consisted in the application of his own methods to histology. How fruitful those methods can be in skilled hands has scarcely been recognized outside Spain, for few have taken the trouble to master all the variations in technique which are needed for different structures. In Cajal's hands and those of his pupils, however, they have resulted in a wealth of knowledge which only of very recent years, by the translation of his *Degeneration and Regeneration of the Nervous System* and his *Histology*, has found its way into the English language. His greatest work, *Textura del Sistema Nervioso del Hombre y Vertebrados*, which began to appear in Spanish in 1897, was translated into French in 1909. Unfortunately it has been out of print for many years, and is now difficult to obtain. Neuro-anatomists know it as the most complete and accurate account of the microscopical anatomy of the nervous system which has ever been written. But its most remarkable feature is that it is chiefly based on Cajal's own studies with silver impregnation techniques.

Since 1901 Ramón y Cajal edited the *Travaux du Laboratoire de Recherches Biologiques*, which was devoted to his own work and that of his pupils and associates. The prestige of this journal has always been high, and its publication in French of recent years has greatly widened its appeal. When he was elected a foreign corresponding member of the British Medical Association in April, 1934, he generously presented to the Association's Library a set of the *Travaux* for the years 1912 to 1933.

As a scientist Cajal ranks very high. Of his many contributions to knowledge few have had to submit to change. Perhaps his very isolation contributed to this result, as it made him observe things freshly with his own eyes and left him free from erroneous tradition. In fact, he insists in several places that his work is individual and Spanish, and deplors the fact that others, without troubling to read the Spanish literature, have rediscovered facts which he and his pupils had observed.

Cajal received abundant recognition during his life, a recognition which meant little to him, except the honour which it brought to Spain and the opportunities which it afforded for further work. He was professor of anatomy at Valencia at the age of 29 and for thirty years, up till 1922, professor of histology and morbid anatomy

at Madrid University. His early book, *New Ideas on the Structure of the Nervous System*, which appeared in 1894, was sold out in Spanish, German, and French editions by 1899. He gave the Croonian Lectures before the Royal Society of London in 1894, and received half of the Nobel Prize in 1906. On this occasion physicians of the Argentine raised a fund for the publication of a book by Cajal, and to this we owe his *Degeneration and Regeneration of the Nervous System*. In Spain also he was honoured by being made a life senator, and a magnificent laboratory in Madrid, El Instituto Cajal, has been erected as a permanent memorial of the man and his work.

We regret to announce the death, on October 10th, of Dr. Thomas Horton in his seventy-ninth year. Dr. Horton was trained as a pharmaceutical chemist, but at the late age of 35 he went to Durham University College of Medicine at Newcastle for his medical training. Two years later he entered University College Hospital, London. He qualified M.R.C.S.Eng., L.R.C.P.Lond. in 1894, and graduated M.B. (with honours) and B.S. at Durham University in the same year. He took his M.D. in 1896. He was Tulloch and Armstrong scholar at Durham University, and gold medallist in medicine and Erichsen prizeman at University College Hospital. He practised at Torquay for over twenty years with considerable success, and was honorary surgeon to the Torbay Hospital and honorary physician to the Western Hospital for Consumption. After his retirement he devoted himself to voluntary work for the Baptist Missionary Society, being successively chairman of the Medical Committee and chairman of the General Committee of that society. He was a keen member of the British Medical Association for some twenty years. His younger son was killed in the Great War. He is survived by one daughter and one son, who is in surgical practice at Weymouth.

Medical News

The centenary appeal on behalf of Charing Cross Hospital Medical School will be inaugurated on Thursday, November 1st, when Marshal of the Royal Air Force Sir John Salmond will distribute the prizes and give an address.

The Semon Lecture, 1934, on "Inflammation of the Maxillary Antrum and other Accessory Sinuses (Some Clinical Manifestations of its Pathology)," will be given by Mr. Herbert Tilley at the Royal Society of Medicine on Thursday, November 1st, at 5 p.m.

A series of lectures will be given at the Central London Throat, Nose, and Ear Hospital (Gray's Inn Road, W.C.), on Fridays, at 4 p.m., from November 2nd to March 29th (excluding December 28th).

Dr. George Barger, F.R.S., professor of chemistry in relation to medicine in the University of Edinburgh, will deliver a course of three lectures on "Chemical Questions Relating to Pharmacology," at the London (Royal Free Hospital) School of Medicine for Women, Hunter Street, W.C., on November 1st, 2nd, and 9th, at 5.30 p.m. Admission free, without ticket.

Dr. A. Goodman Levy will read a paper on "Criticisms of Some Aspects of Psycho-analysis from a Layman's Point of View" before the London Jewish Hospital Medical Society, at the hospital, Stepney Green, E., on Thursday, November 8th, at 3.45 p.m., with the president, Professor Charles Singer, in the chair.

A course of post-graduate demonstrations will be given at the Manchester Hospital for Consumption and Diseases of the Ear, Nose, Throat, and Chest, Hardman Street, Deansgate, Manchester, on Wednesdays, at 4.30 p.m., from October 31st to December 12th inclusive. All graduates and students of medicine are invited to attend.

The Fellowship of Medicine (1, Wimpole Street, W.) announces that further lecture-demonstrations will be given by Dr. Clark-Kennedy at 11, Chandos Street, W.,

at 2.30 p.m. on October 30th and November 6th. In the series of lectures on diet and dietetics, on Wednesdays at 8.30 p.m., at 11, Chandos Street, W., Dr. Leonard Findlay will speak on diet of infants on October 31st, and Dr. E. G. B. Calvert on diet of the diabetic on November 7th. Special demonstration of surgical cases by Mr. C. E. Shattock on November 10th, at 3 p.m., at the National Temperance Hospital, Hampstead Road, N.W. Special courses of instruction include neurology at the West End Hospital for Nervous Diseases, October 29th to November 3rd, all day; obstetrics at the City of London Maternity Hospital, all day, November 3rd and 4th; medicine, surgery, and gynaecology at the Royal Waterloo Hospital, November 5th to 24th, all day; chest diseases at the City of London Hospital, Victoria Park, November 5th to 10th, all day; urology at St. Peter's Hospital, November 5th to 17th, all day; venereal disease at the London Lock Hospital, November 12th to December 8th, afternoons; gynaecology at the Samaritan Hospital, November 17th and 18th, all day; proctology at St. Mark's Hospital, November 19th to 24th, all day; rheumatism at the British Red Cross Clinic for Rheumatism, Tuesday and Thursday evenings, at 8.30 p.m., November 20th to December 6th. A panel of teachers is available for individual tuition. Courses are open only to members and associates of the Fellowship.

Dame Louise McIlroy, who has been appointed assistant director and lecturer to the Clapham Maternity Hospital, Jeffreys Road, London, S.W., is now holding an ante-natal clinic there every Wednesday, at 10 a.m., and giving a weekly lecture.

The Lilly Research Laboratories at Indianapolis, U.S.A., were formally opened on October 11th. At the dedication ceremony addresses on "Research in Manufacturing Pharmacy" were given by Mr. J. K. Lilly, on "The Unpredictable Results of Research" by Dr. Irving Langmuir, on "The Early Story of Insulin" by Sir Frederick Banting, on "Chemical Ideas in Medicine and Biology" by Sir Henry Dale, and on "The Work of the Laboratories" by Mr. Eli Lilly.

It is announced that a committee, including Sir Charlton Briscoe and Mr. Cecil Wakeley, has been formed for the purpose of raising a fund to commemorate the late Miss M. E. Ray, R.R.C., of King's College Hospital. Miss Ray's association with "King's" began in 1889, when, on completion of her training, she was appointed sister of the Albert Ward. In 1896 she became assistant matron of the Leeds General Infirmary, and in 1899 matron of the County Lincoln Hospital. After being there for seven years she was appointed sister-matron of King's College Hospital, a post she held until 1918. For services during the war she was awarded the Royal Red Cross. In 1918 she retired from "King's," and took over the post of honorary secretary of Lady Minto's Indian Nursing Association. It has been suggested that the most fitting memorial to her would be the establishment of a fund to be devoted towards assisting "King's" nurses who are temporarily embarrassed, especially those requiring rest and convalescence after illness. Cheques should be sent to Miss M. A. Willcox, Sister-Matron, King's College Hospital, S.E.5.

The National Council of Women of Great Britain, at its annual meeting held in Edinburgh this month, unanimously adopted a resolution urging His Majesty's Government to require from local authorities strict compliance with their statutory duty to ascertain the number of mental defectives in their area, and to provide for them institutional accommodation and other appropriate means for their adequate care and protection.

On October 1st the British Legion took over, as a seaside annexe to the institution at Preston Hall, Douglas House, Bournemouth, which has hitherto been administered by the United Services Fund as a convalescent centre for tuberculous ex-service men. The institution is approved by the Ministry of Health, and will add seventy-five more beds to the number already available at Preston Hall.

Professor Pavlov, the world-famous physiologist and director of the biological station of Koltouchi, near Leningrad, has recently celebrated his 85th birthday.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and **LETTERS** forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBER** of the British Medical Association and the *British Medical Journal* is **EUSTON 2111** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, Mediscera Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Treatment of Chronic Nasal Discharge

"M.S." writes: Could anyone suggest a hopeful line of treatment for this case of chronic rhinitis? The patient, a woman aged 25, has had the maxillary antra and frontal sinuses operated on, and, later, she tried a course of homoeopathic treatment. She states that the headaches are less severe and less frequent than they used to be, but there is still very copious nasal discharge. Should allergic reaction be tested, or would an autogenous vaccine or some form of light therapy be more helpful?

Age for Dick and Schick Tests

"O. M. H." writes: At what age should children be Dick- and Schick-tested and, if positive, actively immunized?

Localized Flushing

Dr. R. K. ROBERTSON (Sheffield) writes in reply to "H. H. B." (*British Medical Journal*, October 13th, p. 705): I once had a case of patchy areas of flushing in an otherwise healthy young woman, which responded quite well to the following mixture, taken thrice daily:

Quinae sulph. gr. j, acid hydrobrom. dil. m v, syr. aurantii q.s., aqu q.s.

Treatment of Trichophyton Infection

A major of the R.A.M.C. writes in reply to "M.D." who suffers from trichophyton infection: I have a brother who is a chemist. He was out East in a district where medical aid was not forthcoming, and he got dhobi itch. Using his knowledge that the skin is a colloidal membrane, and that glacial acetic acid is known to penetrate a colloidal membrane, he applied to himself pure glacial acetic acid, with an immediate cure. When told of this, I asked if it was painful, and how it was applied. It appears it was not very painful. The acid was dabbed on with a small piece of cotton-wool held in forceps, and there did not appear to be any burning of the skin. I applied this treatment to myself when a bald patch appeared in my hair. Several of the usual ointments failed to stop it spreading. An immediate cure resulted. This might therefore be worth trying in the case of a trichophyton infection. I should advise a very cautious application to a small area, and watch the result before applying it liberally, as from the nature of the drug it is rather drastic.

Dr. WRIGHT LAMBERT (Brentwood) writes: If "M.D." and others infected with trichophyton will try painting the affected parts daily with 1 per cent. brilliant green in rectified spirit I think they will get more relief, if not actual cure, than by any other treatment.

Income Tax

Use of Private Residence

"E. J. N." owns the house in which he lives, and uses two rooms for consultation, etc. One maid is kept at the house, and "E. J. N." rents another house, where the main surgery is situated. What can he claim for the former premises?

** Seeing that most of the callers are apparently dealt with at the rented premises "E. J. N." will probably not be entitled to claim more than 1/3, or even 1/4, of the general expenses (rental value, light, maid's wages, etc.) of his residence.

LETTERS, NOTES, ETC.

Ernest Hart, 1836-1898

Sir D'ARCY POWER writes: E. V. Lucas, C.II., says in the October, 1934, number of the *Cornhill* (p. 410): "Ernest Hart was the founder of the *Lancet* and a great connoisseur of Japanese art." Surely the first statement should not go uncorrected.

** Mr. Lucas would not have fallen into this blunder if he had read Sir D'Arcy Power's memoir of Ernest Hart in the *Dictionary of National Biography*, or Sir Squire Sprigge's *Life and Times of Thomas Wakley*. Hart was born in 1836, thirteen years after Wakley founded the *Lancet*.

Thrush and Pyloric Stenosis

Dr. ROBERT CRAIK (West Ealing) writes: A boy, born in a maternity home, was well till the twelfth day, when he vomited. This subsided, and mother and child were discharged on the fourteenth day. At birth the baby (a first one) weighed 8 lb. 3 oz.; and on discharge 8 lb. 2½ oz. I first saw him on the eighteenth day on account of vomiting. On the twentieth day he was no better, was constipated, and a swab from the mouth soon gave growth of *M. albicans*. Was it possible that his troubles were due to monilial gastritis? On coming home he was fondled by a large family, from one of whom he undoubtedly acquired the infection. His condition fluctuated, but there was no improvement in a week, and there was steady loss of weight. Suspecting pyloric stenosis, he was sent to hospital on his twenty-ninth day, weighing 5 lb. 15½ oz. on admission. He was operated on next day, made a good recovery, and was discharged at the age of 3 months, weighing 8 lb. 9 oz. At 7 months he weighed 16 lb. and had cut two teeth. Doubtless congenital abnormality is the important point, but the lumen is contracted to a varying degree. In this case I think the onset of serious symptoms was determined by the thrush infection, and possibly this is the explanation of the onset in not a few cases.

Mycoidema

Drs. J. RONALD and N. C. F. MILNE write from the Royal Infirmary, Stirling: We have just read Dr. Broadbent's interesting memorandum in the *Journal* of October 13th (p. 679), in which he draws attention to the physical sign of mycoidema. As members of what he describes as the "younger generation of doctors" may we point out that mycoidema (more generally known as "myotatic irritability") is familiar to most Edinburgh students—undergraduates and graduates alike. We venture to suggest that Edinburgh does not stand alone among the teaching schools in imparting knowledge of the significance and diagnostic importance of this phenomenon.

The G.P.'s Nightmare

Dr. CHARLES J. HILL AITKEN (Kilnhurst, nr. Rotherham) writes with reference to the paragraph with this heading (*October 20th*, p. 754): I understand that, many years ago, the late Professor John Chiene had a cartoon of himself—a general surgeon—hanging on to the umbilicus, the only part left to the general surgeon by the specialist surgeons.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 228.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, NOVEMBER 3rd, 1934

CANCER OF THE OESOPHAGUS

BY

H. S. SOUTTAR, C.B.E., D.M., M.Ch., F.R.C.S.

SURGEON TO THE LONDON HOSPITAL

Cancer of the oesophagus still presents one of the unsolved problems of surgery. The deep situation of these growths, their close proximity to the great vessels—the pleura and the bronchi—and the vital importance of the oesophagus itself make surgical attack exceedingly difficult. Secondary growths are, it is true, not a very marked feature, but the explanation of this is to be found rather in the fact that the patients die before any can occur than in any want of malignancy in the growths themselves. The primary growth is often considerable in volume, but in general it is impossible during life to form any true estimate of its extent. This in itself adds greatly to the difficulty of scientific treatment; since if radium is employed it is impossible to say with any certainty where it ought to be placed, or how much should be inserted. In addition, the patient is usually an elderly individual, often in the last stages of exhaustion from starvation, and quite unable to support any attempt at radical surgery.

The first problem in all these cases is to enable the patient to swallow, and this we shall show it is usually possible to accomplish by comparatively simple means. On the other hand, the growths themselves are almost invariably squamous carcinomata, often of a baso-cellular type, such as is known to be highly sensitive to radium, and is constantly treated with success in the buccal cavity. If by some means it were possible to expose the growth to the action of gamma rays in a uniform manner, there is very little doubt that in a certain proportion of cases the growth would disappear, and in a few cases this has actually happened. The difficulties are undoubtedly immense, but they are purely anatomical in nature and should not be insuperable. Their conquest would constitute a really important advance in surgery.

The dimensions of the problem may be gauged from the fact that carcinoma of the oesophagus accounts for a proportion of all cases of malignant disease variously estimated at from 4 to 6 per cent. In this country the annual mortality from the disease is about 1,600, of whom 1,200 are males and 400 are females. But these figures, important though they must be admitted to be, in no way represent the amount of suffering involved to these unfortunate people, condemned, apart from surgical relief, to a lingering and miserable death from starvation.

Pathology

As we have seen, the disease occurs more commonly in men than in women in the proportion of about 3 to 1, but there is a curious distinction between the two sexes, both as regards the age and the site at which it occurs. In men it is a disease of later life, 90 per cent. of the cases occurring after 50, whilst it is far more common in the lower two-thirds of the oesophagus. In women it may occur at a much earlier age, and the incidence after 40 is almost constant, whilst 60 per cent. of the cases

occur at the upper end of the oesophagus. Many of the cases in women, in fact, are of an entirely distinct pathology, and are more correctly described as post-cricoid carcinoma, often arising in the pharynx. Generally speaking, however, carcinoma of the oesophagus may be regarded as essentially a disease of elderly men, in which 80 per cent. of the cases occur at or below the bifurcation of the trachea.

Histologically carcinoma of the oesophagus is almost invariably a squamous epithelioma, sometimes of the basal type, but often showing a number of cell nests and a high degree of keratinization. More rarely a medullary form is seen arising from the glandular structures and consisting of rounded polygonal cells. Spreading by the lymphatics these growths naturally tend to follow these structures round the circumference of the oesophagus and to produce stenosis. Sometimes, however, they remain localized to one portion of the wall, giving rise to a fungating mass, a local induration, or a deep ulcer according to the reaction of the stroma. Thus we may find anything between a soft, sprouting mass of tissue with a profuse discharge, bleeding readily on contact, and a dense fibrous scirrhous producing a tight stricture, which can only be dilated with difficulty.

No one can have studied these tumours post mortem without being struck by their wide extent and their involvement of surrounding structures. Several inches of the oesophageal wall may be entirely destroyed and replaced by growth, and we have had cases where over a long period the patient has swallowed through an intubated mass of carcinoma. The mass of growth may, indeed, protect the surrounding tissues, but ultimately these are opened up so that direct perforation may occur into the mediastinum, the pleura, a bronchus, or even the aorta. The usual termination arises from perforation of the respiratory tract and the rapid development of an acute septic pneumonia, although in a few instances the opening of a large blood vessel closes the scene.

The lymph glands along the oesophagus are usually involved, but distant metastases are unusual, simply because the patient dies before they can occur. There is a curious tradition that carcinoma of the oesophagus is a disease of low malignancy: we regard it as one of the most highly malignant tumours appearing in elderly people, only failing to give rise to secondary deposits because it destroys the individual by its local extension.

Clinical Course

In the great majority of cases the first symptom in carcinoma of the oesophagus is a steadily increasing dysphagia. Occasionally the onset is so abrupt that the patient thinks that some foreign body, such as a fish bone, has stuck in his throat, but usually it is gradual in onset and without remission. Solids are, of course, first affected, but in most cases the slowness with which

liquids can be swallowed will attract attention at an early stage, and this difficulty is often accompanied by regurgitation of unaltered food. The inconvenience is increased by the secretion of quantities of viscid mucus, which fills the oesophagus and impedes swallowing. Sometimes when this has been ejected as a quantity of white froth swallowing becomes comparatively easy. We have come to regard this white froth as a diagnostic feature of the first importance. In the later stages it is blood-stained and foul, indicating a fungating growth with extensive ulceration, and producing a marked fetor of the breath.

In a few cases where the growth is at the lower end of the oesophagus the symptoms are rather those of flatulent dyspepsia, a feeling of fullness after meals, and the eructation of gas. These symptoms may suggest gastric carcinoma, and, indeed, in some of these cases the growth has arisen in the stomach itself and invaded the cardiac orifice. The same symptoms may, however, appear with true carcinoma of the oesophagus. Pain is not usually an early symptom, but a reflex spasm which results from attempts at swallowing may lead to acute discomfort. In the late stages, where the dorsal roots, or even the vertebral bodies, may be involved, pain may be a very severe feature. Hoarseness and aphonia may occur from involvement of the recurrent laryngeal nerves, and in a few instances these have actually been the first symptoms of the disease.

Involvement of the respiratory passages gives rise to by far the most important group of secondary symptoms. Irritation of the upper passages produces a profuse secretion of a tenacious stringy mucus, which causes great annoyance, and often a constant irritable cough. In late stages involvement of the tracheal wall may give rise to respiratory embarrassment, and we have actually seen a nodule of growth perforating the trachea and producing obstruction. More common, however, is the formation of a fistula into the trachea or bronchus, or into the lung itself, followed by the development of a septic pneumonia as a terminal event.

Wasting occurs from pure starvation, and, in contrast with carcinoma of the stomach, the patient, far from having a loss of appetite, suffers severely from hunger and thirst. That starvation is the cause of the wasting is shown by the rapid improvement which occurs when the patient is enabled to swallow or is fed by a gastrostomy. In the later stages, on the other hand, if the patient is unable to swallow, the general discomfort, the constant pain, and the persistent cough have a very serious effect upon his condition.

Examination of a Case

Of the methods of examination available we shall only describe radioscopy and oesophagoscopy, for the passage of bougies is both useless and dangerous.

X-ray examination, in our opinion, entirely eclipses any other method. It is extremely simple and it is absolutely safe. In every case it will indicate the level of an organic obstruction, whilst in the great majority it will, if properly conducted, give indisputable evidence of the nature of the lesion. The picture furnished by a carcinoma is usually so characteristic that a mistake is scarcely possible. The patient should stand with his left arm above his head facing the screen obliquely, so that the rays pass through the thorax from left posterior to right anterior. In this way the spine, heart, and great vessels are avoided and the clearest picture is obtained.

He now swallows a thick emulsion of barium sulphate of the consistency of a viscous syrup. The emulsion is seen to reach the obstruction and to fill up the lumen of the oesophagus above it. Except in the rare cases when the obstruction is absolute, it will now be seen to trickle slowly through it and to fill up beyond it the longitudinal

folds in which the mucous membrane of the empty oesophagus normally lies. In the case of a malignant stricture a moderate degree of dilatation may be observed above, the shadow will terminate in a cone pointing downwards, and from the apex of the cone a fine pointed stream of barium will be seen making its way through the tortuous vagaries of the growth. A film will show these details even more clearly than the screen, and will supply permanent objective evidence of the nature of the obstruction.

The ordinary barium examination, carried out in an upright position, only gives information as to the condition of the oesophagus above the stricture. We owe to Ledaux of Brussels the ingenious suggestion that the patient should be made to swallow a certain quantity of barium into the stomach and then be examined on a couch in a high Trendelenburg position—in other words, standing on his head. If the patient now attempts to swallow, the cardiac orifice opens synchronously as a part of the normal mechanism, and the barium flows back into the lower portion of the oesophagus. In this way the extent of the stricture can be accurately defined.

Finally comes direct examination with the oesophagoscope, undertaken with a view to discovering the character of the growth and its possibilities of treatment, rather than for the mere diagnosis of malignant stricture. The information obtained may be of very great value, but it is not a manipulation to be undertaken lightly, for except in expert hands the instrument is by no means free from danger. With the patient lying flat, and the head slightly extended and deflected to one side, the oesophagoscope is inserted at the angle of the mouth and passed into the oesophagus under the control of vision. The passage through the upper sphincter is sometimes difficult, but once it is overcome the whole oesophagus can be explored with ease. In its whole thoracic course the lumen will be seen as a narrow transverse slit which opens and closes with each respiration. On reaching the aperture in the diaphragm the slit becomes antero-posterior and ceases to expand, whilst immediately beyond this the cardiac orifice of the stomach appears as a rosette of fine mucous folds. On entering the stomach itself the large folds of gastric mucosa are seen, and there is usually a gush of fluid into the instrument. Manipulations must be carried out with the greatest care, since the oesophagus itself is always fragile, and it may be deeply ulcerated in the presence of a malignant growth.

The lumen of the normal oesophagus appears on direct examination as a transverse slit which opens and closes with each respiratory act. If the wall is infiltrated these movements cease, whilst dilatation of the lumen above the stricture will be immediately obvious. A puckered stricture, a fungating mass of growth, or an ulcerated area can readily be observed, and occasionally it may be practicable to remove a fragment of growth for section, though we do not advise this as a routine procedure. But the chief use of direct examination is for dilatation of the stricture, to which we shall later refer.

Treatment of Oesophageal Carcinoma

It is only rarely that the question of radical removal of a carcinoma of the oesophagus can even be raised, and in spite of a few brilliant results it seems to us most unlikely from the pathological considerations which we have already described that it can ever become a practical method. The depth at which the oesophagus lies, the fragile nature of its wall, which possesses neither a sub-mucous nor a peritoneal coat, the complexity of the structures by which it is surrounded, and the age at which the disease occurs are all opposed to a direct attack, and one may be sufficiently grateful if one can relieve the dysphagia. For this we have three methods

at our disposal: dilatation, intubation, and gastrostomy. The last is, of course, a confession of surgical failure, but it by no means follows that in some cases it may not be the soundest practice. We would only say that if it is to be performed this should be done at an early stage, and not left until exhaustion has increased its danger and diminished its utility. Our own practice is to attempt to relieve the dysphagia directly, and, if this fails, to perform gastrostomy, although in certain cases where the patient's condition has been desperate we have first performed gastrostomy in order to save his life.

Dilatation should only be attempted under the direct control of the oesophagoscope. We first pass a fine flexible bougie on the end of a long steel wire, which does not interfere with vision. Over this are passed tubular dilators of increasing size, formed of short cylindrical rods of aluminium, with an axial hole which slides easily over the wire guide. The dilators rise by millimetres from 4 to 11 mm. in diameter, and by passing them in turn it is usually quite easy to dilate the stricture up to the full size. As the dilator is passed through and clears the stricture, or as it meets it on its return, a fair estimate of its length may be obtained. Even with these dilators it is, of course, necessary to proceed with great caution and gentleness, and to remember the extreme fragility of the oesophageal wall.

Dilatation is usually followed by immediate relief of the dysphagia, but this is likely to recur in a few weeks' time. To avoid this we devised, some years ago, a flexible tube formed of a spiral of German silver wire, with an expanded upper end and a twisted oval section which prevents its upwards displacement. These tubes are now in general use, and from their extreme flexibility they are readily tolerated, the patient being usually quite unconscious of their presence, whilst the large lumen allows ordinary food to pass. With reasonable care in mastication or in the preparation of food the tube should not become blocked, and we have had a large series of cases in which the patient was able to eat a dinner without difficulty. There was a slight difficulty in the introduction of these tubes, which we have now overcome by a very simple device. It was found that even after full dilatation the lower edge of the tube tended to catch on the end of the growth, and refused to pass through the lumen. This can be entirely avoided if before introduction a small cone of gelatin is inserted into the end of the tube: a glycerin suppository of suitable size answers perfectly. The facility of introduction produced by this simple device is very remarkable, and the gelatin dissolves in a few minutes and passes on down the oesophagus.

Treatment by Radium

These methods aim solely at the relief of dysphagia and not at the cure of the disease. So far as can at present be seen it is only with some form of radiation that we can hope to effect this, and we have at our disposal radium and x rays.

Of the methods of radium treatment which have been adopted the most direct is by the insertion into the lumen of the tumour of a sound containing radium. After exact measurements have been made of the position and extent of the stricture, a rubber sound is prepared containing within its cavity a series of radium tubes each 2 cm. in length, filtered by at least 1 mm. of platinum, and each containing 10 mg. of radium element. Three or four such tubes may be used according to the length of the stricture. The sound should be made of rubber, containing no metal, and should have a wall of at least 2 mm. in thickness, and it is convenient to block the lower end of the sound with a wooden or vulcanite rod 2 cm. in length. The sound is passed until a mark made upon it registers with the teeth and indicates that the

radium is in position, and it is then brought round the cheek and secured either by plaster or by a string passed round the ear. The tube should be retained in place for forty-eight hours, and this treatment should be repeated on three occasions in all, so that the total dose of 30 to 40 mc.d. is received.

More comfortable for the patient when it can be adopted is the method suggested by Madame Simone Laborde. A rubber sound is prepared, as already described, but only of slightly greater length than the region to be treated. The sound is attached to a stout thread and is simply swallowed by the patient. Its progress is noted on an x-ray screen and the thread is secured to a tooth or to the cheek when the sound is correctly placed. The weight of the sound and the platinum it contains assists its progress and prevents its regurgitation. The sound can be left in place for six or eight days provided a gastrostomy has been performed, but the dose received ought not to exceed 30 to 40 mc.d. In view of the fragility of the oesophagus, and our ignorance of the extent of the growth, a larger dose involves too great a risk of perforation. If no gastrostomy has been performed it is scarcely possible to retain the tube in position for more than eighteen hours, but it may be replaced after a day's rest and the treatment continued until a full dose has been received. The procedure, of course, assumes a permeable stricture into which the sound can pass, but given this condition very satisfactory results have been obtained, although so far only of a temporary nature.

Where intubation with my own spiral tube can be effected, this may very conveniently be used as a support for radium. A narrow gold tube, about six inches in length, is filled with radon gas. The ends are sealed, and one end of the tube is wound into a circle half an inch in diameter to form a ring to which a thread can be attached. This is lowered into the spiral tube, the ring resting on its upper aperture. The emanation tube does not interfere with the passage of liquids through the intubation spiral, and is easily withdrawn at the end of forty-eight hours.

A method which we have used extensively is the introduction of seeds by means of the oesophagoscope into the substance of the growth itself. With a large oesophagoscope a full view of the upper surface of the growth is easily obtained, and it is then quite easy, by means of a special introducer, to insert seeds into the substance of the growth to any depth that may be desired. We have made a practice of introducing two rings of seeds at different levels, and in this way it can be shown on radiographic examination that a fairly even distribution of the seeds has been obtained. It might seem that the proceeding was essentially dangerous, since it is impossible to guarantee that the seeds will not enter the mediastinum or the surrounding structures, but in well over a hundred cases we have never had any trouble attributable to this cause. Perforation of the oesophagus under normal conditions would produce certain death from infection of the mediastinum, but it must be remembered that the seeds are necessarily sterile and that no organism can grow in their neighbourhood. In a few cases a fairly satisfactory result has been obtained, the patient recovering his power of swallowing and being restored to a condition of health. In no case, however, have we succeeded in effecting a cure, all the patients having died within a year. If some means could be discovered of defining the limits of the growth it is possible that much better results could be obtained.

So far as we are aware, no attempts have been made, at least on any scale, to treat carcinoma of the oesophagus by accurately directed radium beam radiation. From the depth at which the oesophagus lies it is obvious that a very large source would be required, but, apart

from this, there would not appear to be any considerable difficulty, for with reasonable care the heart and lungs are not likely to suffer from ill effects: On general grounds one would expect that such a method ought to produce more satisfactory results than any of those hitherto employed, since the growth with which we are dealing is certainly radio-sensitive, and the only real danger is that by too energetic a dose we may produce sloughing of the tissues and perforation. Combination with internal radiation from a tube or from seeds would seem to be a rational method, but so far it has not been developed.

Deep X Rays

Results of great interest have recently been obtained by Levett using deep x rays, the radiation consisting of very hard rays and being limited to a narrow field, including seven inches of the oesophageal wall. It is still too early to speak with any certainty of the results secured, but in a few cases at least it would seem that complete healing had been obtained without secondary stenosis. Hitherto the disadvantage of x-ray treatment in these cases has been the intensely depressing effect upon the patient, due apparently to the effects of the x rays upon the surrounding structures, and perhaps to the absorption of products so formed. So severe have been these effects that radiologists of the brilliant achievement of Coutard have entirely abandoned the method. If, however, these secondary effects could be avoided by skilful adjustment of the apparatus, the method would appear to have definite possibilities, and it is certainly one which should be explored to the full.

Another method which we are at present ourselves investigating is the application of radon to the outer surface of the oesophagus after exposure by transthoracic exploration. It is a very remarkable fact that even in elderly subjects the lower half of the oesophagus can be fully exposed by the transthoracic route apparently without risk and with only trivial inconvenience to the patient, far less in fact than is associated with an ordinary laparotomy. Theoretically, if a growth of the oesophagus could be surrounded by a group of radon seeds there is little doubt that the growth would entirely disappear and that healing of the mucosa would occur. The mechanical problems involved are, however, difficult to solve, and in spite of a few encouraging examples we can still only regard the method as in the experimental stage.

Conclusions

It will be seen, then, that for the present we regard the relief of dysphagia as the one object to aim at in the treatment of carcinoma of the oesophagus, and we consider the introduction of a spiral tube as the method most likely to achieve this in practice. Our personal experience of the method now extends over some fifteen years, and includes upwards of 300 cases, whilst the method is in general use by many other surgeons. We consider, however, that every attempt should be made to develop the method of radiation both by radium and by x rays, since although both of these are still in the experimental stage they are probably the only methods to which we can look for any real prospect of curing the disease.

ADOLESCENT AND SENILE KYPHOSIS*

BY

C. LAMBRINUDI, F.R.C.S.

ASSISTANT ORTHOPAEDIC SURGEON, GUY'S HOSPITAL

(With Special Plate)

It is about time that opportunity was given for the ventilation of ideas upon the difficult and puzzling subject of adolescent kyphosis. Though the literature is now abundant, most of the work seems to have been done by American, French, German, and Italian authors, and very little by Englishmen. It was not until Beadle¹ and Ross-Smith² published their papers in 1931 on the intervertebral disk that much thought was given to this structure in Great Britain, or to the possible association of its pathological conditions with adolescent kyphosis. It seems strange that this should be so, for it cannot be doubted that the condition has long been recognized here by orthopaedic surgeons and those working in institutions for surgical tuberculosis. In fact, one of its chief claims to recognition is that adolescent kyphosis, on account of its occasional combination of pain, deformity, and peculiar x-ray appearances, constitutes one of the most important differential diagnoses from spinal caries. Sorrell³ says that 25 to 30 per cent. of cases sent to his hospital with a diagnosis of spinal caries turn out to be cases of adolescent kyphosis.

Clinical Picture

Obviously, unless one has worked on this comparatively rare condition for a long time, it is difficult to collect a sufficient number of cases to give any valuable statistics on the relative frequency of any particular type of onset. I shall therefore content myself by merely enumerating the varieties.

Adolescent kyphosis starts between the ages of 12 and 17, normally a period of active growth, and is said to be more common in boys than in girls. The deformity may become exceedingly unsightly (Fig. A), but the active process tends to cure itself spontaneously in the course of eighteen months. If treatment is carried out early the deformity may even be lessened, but it is doubtful if it can ever be entirely corrected. In my small group of cases, and from a perusal of the literature, I think I can detect five different classes.

1

The onset is insidious. Kyphosis gradually develops, but the patient himself is unaware of it. He is usually brought up for advice by his parents, who are alarmed at the deformity. There is, however, no pain—at most a sense of fatigue at the end of the day or after exercise, but often not even that. There may be no history of trauma, and he appears to be in perfectly good health and of normal development. The posture is poor on account of the round back, but the musculature is good and there is no spasm. The kyphosis, however, cannot be corrected either actively or passively, and there is often a certain amount of rotation of the vertebrae. The hamstring muscles may be short.

2

In this group the onset is also insidious, but the patient belongs structurally to an altogether different type. The child is tall and lanky, and there may be a history of debilitating illnesses in childhood following rapidly one upon another. The musculature is inadequate, and the posture is very bad. He complains of backache, which appears, however, to be due to fatigue. In him, too, the movements of the spine are not restricted by spasm, but the hamstring muscles are markedly contracted. He belongs, in fact, to the type of child who acquires postural deformities, but in whom the kyphosis becomes fixed earlier than usual.

3

In this class are included those cases in which the onset is fairly sudden. There may be a history of a fall a month or so previously, or a period of exceptional activity at work or at play. Scheuerman,⁴ who first drew attention to the condition in 1920, was so impressed by this that he called it

* Read in opening a discussion in the Section of Orthopaedics at the Annual Meeting of the British Medical Association, Bournemouth, 1934. The author's section on Senile Kyphosis has been omitted for reasons of space.

"apprentice kypnosis." Pain is a very definite feature, and there is said to be sometimes a rise of temperature. The pain is never very acute, but it is sufficiently severe for the patient to seek advice on account of it. The movements of the back are restricted by spasm, and the spinous processes are said to be tender on pressure. The symptoms disappear with rest, and the kypnosis may even improve a little.

4

In this type the patient is definitely overgrown. One of my cases, a boy of 15, was 6 ft. 1 in. These cases, however, differ from those in Class 2, inasmuch as their musculature is not so poor and they exhibit other signs of endocrine disturbance. Albanesi has collected a number of cases in which changes are seen in the sella turcica and also in other parts of the skeleton, suggestive of an endocrine imbalance.

5

Some cases have been described as coming on rapidly after an acute pneumonia. Albanesi² refers to this, and Edelstein, who has written on the subject, has told me that he quotes one such case.

Although the mode of onset and the type of patient may be varied, there are certain clinical features common to all classes.

1. The kypnosis is always round and never angular.

2. The kypnosis is always in the lower dorsal region.

3. The x-ray appearances are constant and characteristic.

4. The hamstring muscles are, I believe, usually short.

Scheuerman and the French school lay great emphasis upon pain in these cases. In fact, they have termed the condition "painful kypnosis of adolescence." I do not think that this is by any means a constant feature, and if we were to restrict ourselves in this discussion to those cases alone which have pain I feel sure that we should overlook a lot of important details.

X-Ray Appearances

In a fully developed case, where the active process has ceased, the vertebrae from the seventh dorsal to the first lumbar (often fewer, but rarely more) are wedge-shaped. The intervertebral disks are narrowed, and the vertebral borders, above and below, are sclerosed with punched-out areas in them, looking moth-eaten. In the early stages the point that Buchmann⁶ lays great stress upon is that the adjacent vertebral borders are indistinct and irregular, and even the whole vertebral body may become hazy. The epiphyseal points may be delayed in their appearance, and when they do appear they are denser than normal. As regression occurs the definition of the vertebral bodies becomes clearer and the epiphyseal plaques seem to be fragmented and dense. It is only in the later stages, when the whole of the plaque has become sclerosed, that the typical punched-out conformation can be seen.

Aetiological Factors

Whitman,⁷ in discussing coxa vara, says that the condition is due to a discrepancy between strain and stress on the one hand and the capacity of the bone to bear it on the other, and it will be useful in reviewing the theories

of aetiology of adolescent kypnosis to divide them into these two main headings.

Factor of Weight-bearing Capacity

The conditions which diminish the capacity of the bone to bear weight are: (a) circulatory; (b) infective; (c) endocrine or metabolic disturbance; (d) physiological weakness; (e) hernia of the intervertebral disk (Schmorl's theory). I will now discuss these seriatim.

Circulatory

Owing to the fact that specimens of Perthes's disease show that the bone nucleus has undergone a necrosis, some authors seek to explain, not only Perthes's disease, but most of the other osteochondritides and epiphysites as being due to embolism. So far as the back is concerned, however, it is difficult to see how emboli could reach simultaneously a limited number of vertebrae over a certain area of the spine at a certain age. It appears to me to be a very far-fetched theory.

Infective

Despite the fact that it is exceptional for organisms to be found in any of these epiphyseal conditions, the infective theory still has a large number of supporters. Those who favour this view do so because they think that it best explains the radiographic appearances, but I find it difficult to believe that infection which is sufficient to cause destruction of bone can occur without pain or occasionally giving rise to abscess formation. Apart from the jaw, I do not know of any other situation where there is chronic

FIG. A.

FIG. B.—To show deformity and short hamstrings.

infection in bone without pain. It is upon this question of pain where my experience, as far as it goes, differs from that of other authors. There are some cases of adolescent kypnosis where pain is a prominent symptom and even a rise of temperature has been recorded; but these are few, and in most cases where pain exists it is not of an inflammatory nature.

If infection does play a part at all, it must be of the very mild and transient kind which gives rise to thromboses, similar to spontaneous thromboses elsewhere in the body. Such disturbances of the circulation weaken the bone, and any subsequent changes are of a secondary nature owing to the peculiar mechanical arrangements that prevail in the intervertebral disk, and not to the destructive action of the organism itself. This infection would have to be of a very special kind, having an affinity for the blood vessels of a limited number of vertebrae, over a certain area of the spine, at a particular age! But what explains those cases of adolescent kypnosis that come on acutely during the course of a pneumonia?

Thanks to the writings of Watson Jones, spontaneous dislocation of the atlas, associated with an acute or chronic pharyngitis, is now a well-established, though rare, clinical entity. The hyperaemia produced by the pharyngitis causes decalcification of the bone and slackening of the ligaments, permitting a dislocation; but it must be noted that in this region no intervertebral disks exist. I do not think it is straining the imagination too far to presume that a similar condition might exist lower down the spine.

Supposing, during the course of a bronchopneumonia, the mediastinal glands were to become inflamed (as they undoubtedly do): this might produce decalcification of the vertebral bodies, and any minor traumata during the course of nursing, or maybe a paroxysm of coughing, might result in subchondral fractures. A dislocation, of course, could not arise because of the presence of the intervertebral disks. One of my colleagues has promised to x-ray the dorsal spine of every child convalescent from bronchopneumonia, and in the course of time I confidently anticipate to be able to report that the sequence of events I have visualized does occasionally occur. To sum up then: infection, in the sense of invasion by organisms, though it may be responsible for some cases, is probably a very rare cause.

Endocrine and Metabolic Disturbances

Late rickets has, at one time or another, been held responsible for this and all other epiphysites. Several cases were reported in Vienna during the famine stages of the war, but in these the disturbances were more widespread, and it can be assumed not to be an important factor in normal times.

I have already mentioned Albanesi's researches, and I believe his article to be an important contribution to the literature, but I feel inclined to take the view that Whitman takes in regard to coxa vara: which is that where coxa vara coexists with Fröhlich's syndrome the cause of the slipping is more likely to be due to the abnormal weight the epiphyses have to carry than to the fact that the endocrine disturbances affect the quality of the bone or its growth. One of the reasons which I think support this view is that only those epiphyses which have to withstand a shearing strain, such as the hip, the knee, and the dorsal vertebrae, appear to be affected. There are no changes in the ankle-joint, for instance, in Fröhlich's syndrome, in spite of the fact that the weight borne by the ankle-joint is greater than that borne by any of the other joints: this is undoubtedly due to movements of the subastragaloid joint, which protects the lower tibial epiphyses from a shearing strain. In connexion with this, it is interesting to note that Buchmann alludes to a case where adolescent kyphosis coexisted with changes in the epiphysis of the iliac crest. At first sight this might appear to be a case of multiple epiphyseal lesions of the endocrine or metabolic variety, but when one reflects that many powerful ligaments are attached to the posterior part of the iliac crest, in order to control the rotatory movements of the sacrum, the occasional combination of what one might call a "pulled" epiphysis of the ilium with adolescent kyphosis supports rather than refutes the strain theory.

Physiological Weakness

Murk Jansen⁸ has enunciated the theory of the vulnerability of rapidly growing young cells, and it would seem from this that during periods of rapid growth the bones are weaker. Generally speaking, there are two periods in which growth is particularly active—between 3 and 6, and between 12 and 17 years. During these two periods there may be said to exist a state of physiological weakness of the bones. Supposing that during either of these stages the back was subjected to undue strain or varying degrees of trauma, disturbances of growth might be expected to arise. This point will be referred to again later, in discussing short hamstring muscles.

Hernia of Intervertebral Disk: Schmorl's Theory

Thanks to the writings of Calve,¹⁰ Gallrand,¹¹ and Beadle, the ideas of Professor Schmorl⁹ are gradually becoming better known. He has collected and examined more than four thousand spinal columns, and his views are of considerable interest and practical importance. He

was the first to point out that the substance of the intervertebral disk might prolapse into the vertebral body.

The intervertebral disk is a complex structure, and consists of the nucleus pulposus, the cartilage plate, and the annulus lamellosus. The *nucleus pulposus* is a remnant of the notochord. It is a semi-fluid structure, and in normal circumstances is under very considerable pressure, estimated by Petter¹² as 30 lb. It varies in its position according to the level of the spine, being placed more anteriorly in the lumbar than in the dorsal region; and it is capable of a certain amount of shifting, depending on the position of the vertebrae above and below it. Its function is to act as a water-cushion and also as a pivot upon which the movements of the vertebrae take place. Being a water-cushion, it distributes the pressure equally over the whole surface of the bones, and prevents any one part of the bone bearing more weight than another. If such a mechanism did not exist—for instance, in the dorsal region, where there is already a normal kyphosis—the anterior parts of the bodies of the vertebrae would bear most of the weight and, according to the laws of growth, would eventually become wedge-shaped. The *cartilage plate* is a layer of hyaline cartilage attached to the surface of the vertebral bodies. On its bony aspect it plays the part of an epiphysis, and on its intervertebral aspect its chief function is to prevent the pressure atrophy of the subjacent bone, due to the turgidity of the nucleus pulposus. The *annulus lamellosus* serves to attach the two cartilage plates to one another, thus encapsulating the nucleus pulposus. Its fibres arise from the matrix of the cartilage plate above, and are inserted into those of the vertebrae below, and also into the fronts of the bodies of the vertebrae and the anterior longitudinal ligament. It is an extremely strong structure, and has a fair amount of elasticity.

It will thus be seen that all the structures of the intervertebral disk are subservient to the preservation of the nucleus pulposus. Since this latter is of great importance to the spine anything which interferes with its turgidity or mobility must be detrimental. During the course of development of the vertebrae, that part of the body in the region of the nucleus pulposus may be defective, so that it becomes, so to speak, encased. All the elements of the disk may be intact and healthy, but since the nucleus pulposus is rendered immobile it is not available for its weight-distributing function, and consequently the vertebrae tend to become wedge-shaped, and kyphosis results. Kyphoses of this nature, though they do not show the typical x-ray appearances, ought to be included in this review of adolescent kyphosis.

The point upon which Beadle lays great emphasis is that, when viewed phylogenetically, the erect posture is a comparatively recent event, so that the spine as a whole has not yet completely adapted itself to its new function—that of weight-bearing. As a result of this, certain elements of it are prone to premature degeneration. That part of the intervertebral disk which is apparently most vulnerable is the cartilage plate. Minute rents can frequently be seen in it, rents which are assumed to be caused, not by any one gross trauma, but by the wear and tear of an ordinary life. Where these rents appear, the nucleus pulposus, owing to its turgidity, insinuates itself and gradually prolapses into the bone. Schmorl has found evidence of these herniae in as many as 38 per cent. of all spines examined. They are always in the lower dorsal and upper lumbar regions, and are of three kinds. The commonest is a vertical protrusion of the nucleus pulposus into the vertebral body; occasionally, if the bone is resistant, the hernia can worm its way anteriorly between the cartilage plate and the bone; and, finally, the herniae may be in front of the nucleus pulposus and consist of the disk substance only.

Schmorl considers that a large number of cases of adolescent kyphosis are the result of these hernial protrusions. Those who support this view explain the radiographic appearances by assuming that the presence of a

foreign body in the bone produces hyperaemia, with its consequent decalcification. Hence the x-ray photograph of an early case shows lack of definition. But, as reaction occurs, the bone becomes sclerosed in order to prevent further incursions of the hernia, and it is only when this is completed that the typical moth-eaten conformation can be seen in the x-ray film. Furthermore, the hernia theory has some experimental support. Keyes¹³ and Compere¹⁴ very carefully injured the cartilage plate in a dog, and found that disk herniae invariably followed. Mauric¹⁵ quotes the observation of Meyer, who was able to get a necropsy of a case showing typical x-ray appearance, and found that the indentations corresponded to a discal hernia. It can therefore be taken for granted that these herniae do exist.

Examination of Schmorl's Theory

The first criticism which comes to mind is that, if discal herniae are so common as to occur in 38 per cent. of spines, why is adolescent kyphosis such a comparatively rare condition? The answer seems to be that the point of chief importance is the age at which these herniae arise. If they appear in later life, in the line of the nucleus pulposus, which is the commonest site, the secondary changes in the spine are those of an osteoarthritic nature, owing to the loss of function of the nucleus pulposus; but, if they appear earlier they give rise to abnormalities of growth. Schmorl is under the impression that these herniae are of congenital origin, or, alternatively, that there is a congenital weakness of the cartilage plate sufficient for it to undergo early degeneration. Anyone who has seen Schmorl's pictures, or read Beadle's account, cannot doubt that congenital abnormalities of the disk do exist, but I am not aware of any developmental reason why the lower dorsal and upper lumbar regions—the parts most affected in adolescent kyphosis—should be more prone to congenital malformation than any other. Also, I do not see the necessity of invoking the aid of such a hypothesis as a predisposition to premature degeneration of the cartilage plate in order to support Schmorl's theory, because that part of the spine is the most vulnerable and most liable to flexion traumata in any circumstance.

Those who oppose Schmorl's hypothesis do so because they think that it does not explain all the radiographic findings. We have already seen how some of them—namely, the early decalcification and later sclerosis—can be explained; but it is more difficult to account for the late appearance, the large size, and the marked opacity of the centres of ossification of the epiphyseal ring. Too much stress should not be laid upon the time factor in the appearance of these centres of ossification, because it is known to vary. But there is no doubt that when they do appear the x-ray picture is very similar to the changes seen in osteochondritis elsewhere. In all these latter the density is said to be due to necrosis of the bony nucleus. There is one important distinction, however, and that is that in adolescent kyphosis the dense centres are larger than normal, whereas in osteochondritis they are invariably smaller. Furthermore, I think that in adolescent kyphosis these centres fuse with the body of the vertebra earlier than usual—a fact that can hardly be reconciled with an idea that presupposes death of the bone.

It is customary, when one sees radiographic changes in the epiphyses, to regard them all as pathological, but the point I would like to make is that we do not know what changes, if any, take place in circumstances of a reactive nature which demand the rapid appearance and rapid fusion of an epiphysis. I am inclined to regard the changes in the centres of ossification of the epiphyseal ring as evidence of reaction against the invasion of a hernia, as an attempt to hasten its fusion with the body

in order to offer a greater obstacle to the incursion of a peripherally placed hernia.

To sum up, then; though some cases of adolescent kyphosis may result primarily from congenital abnormalities of the intervertebral disk, I think it is more reasonable to regard the discal herniae as secondary changes and as the inevitable complication of any process which weakens the cartilage plate or the underlying bone. This weakness may occasionally be caused by the variety of conditions already referred to, but the most important factor is stress and strain due to an abnormally heavy body, and more especially oft-repeated minor traumata.

The Effect of Stress and Strain

The factors which increase strain and stress are: (a) body weight, (b) trauma, and (c) short, hamstring muscles. Most of the theories so far examined presuppose the existence of an exciting cause—and that is

DIAGRAM I

A, Normal position for toe-touching. Note that contour of the back is regular. Anterior superior spine of the ilium on the same horizontal plane as the top of the great trochanter. Spring in the hamstring muscles not stretched.

B, Normal back flexed beyond comfortable limit. Note that the contour of the back is unchanged. Anterior superior spine below the level of the great trochanter. Hamstring spring stretched.

C, Short hamstrings. Note that the anterior superior spine is above the level of the great trochanter. Contour of the back is normal.

D, Short hamstrings. Back flexed beyond normal limits, showing the increased convexity of the lower dorsal and lumbar regions.

generally held to be stress and trauma. Reference has already been made to the influence of body weight in discussing the endocrine theory, and there is no need to enlarge upon the accident of a strong flexion force in a growing child as a cause of injury to the spine. But since the history of trauma often cannot be elicited, one must look for another explanation.

When a normal child (Diagram I—A, B, C, D) stoops down to touch his toes with the knees extended the contour of the back is regular and graceful, and the hamstring muscles are not tight. In this position the back itself is locked in full flexion, but the pelvis is not fixed, as there is some give in the hamstring muscles. Therefore, if a force falls upon the back, making it flex further, the hamstring muscles act as a spring (Plate, Figs. 1 and 2). On the other hand, if the hamstring muscles are tight, then in the stooping position not only is the back flexed to its maximum but the pelvis is fixed, for there is no spring action in the hamstring muscles. Since the back

of a child, even when fully flexed, is more resilient than the contracted muscles are stretchable, any force falling on the back will tend to hyperflex the spine and throw all the weight on the anterior parts of the bodies of the vertebrae (Figs. 3 and 4).

Influence of Hamstrings on the Back

Several years ago, when treating a child for bad posture by the usual method of remedial exercises, I noticed that it gradually got worse. Rotation of the lumbar vertebrae, which had not existed, became apparent. On further examination I found that the hamstring muscles were short—more so on the side of the rotation. With the kind permission of the medical officer of health and the school authorities of the L.C.C. I have examined a large number of school children for two years in succession with the idea of determining what proportion of them had short hamstring muscles. I found that it was common, but rarely existed before the age of 6. It was more frequently unilateral than bilateral, and in the former there was invariably rotation of the lumbar vertebrae towards the shortened side. Sometimes, even, the rotation was generalized. It was rare to find both hamstring muscles equally short, but when it did exist the contour of the back in flexion was much more curved (Figs. 5 and 6), the point of the greatest convexity being the lower dorsal and upper lumbar regions. In the bilateral cases, however, it was more common to find one side shorter than the other—usually the left—in which case there was always rotation of the lumbar vertebrae to the shortened side (Figs. 7, 8, and 9), and the point of greatest convexity in the contour was always in the lower dorsal region.

It was interesting to note that in the majority of cases the shortening of these muscles was transient. Children who were unable to touch toes by six inches or more in one year could do so the next, while some who could the first year were not able to the following year. This latter was most evident in children who had grown rapidly in the interval. In a smaller proportion of cases there was no tendency to improvement, and this was most marked in the long, lanky, flat-backed child, but not invariably so.

These are facts that can be verified by anybody who takes the trouble to do so. The point of interest is whether they have any bearing on the subject under discussion. I think they have. It seems to me that the back of a child which has not got the protective spring action of the hamstring muscles must be regarded as a vulnerable back. The inability to touch toes is in itself not important, but it is the loss of the spring action, due to the shortness of the hamstring muscles, that matters. It may be argued that bending down with the knees extended, a position in which the spring action is most necessary, is not a common attitude for a child to adopt; but one must remember that sitting up from the recumbent position is the equivalent of it (Figs. 10, 11, and 12), that it is frequently assumed when playing leap-frog, and that, most important of all, toe-touching is one of the routine exercises in the gymnasium classes at school.

I have seen children who are unable to touch their toes being exhorted to do so by a series of sudden jerks. The practice of using the back of a growing child as a lever (and a flexible one at that) to stretch the comparatively unstretchable hamstring muscles is a pernicious one. Such movements must cause considerable pressure on the front of the bodies of the vertebrae, and, as judged from the contour, it is upon the lower dorsal and upper lumbar regions that the brunt of the force falls. If the force is sufficiently powerful and frequent it is not difficult to conceive of minor injuries, such as small crush fractures or subchondral haemorrhages, occurring in the region of

the epiphyseal plaques. Furthermore, and most important of all, when one reflects that the annulus lamellosus arises from the matrix of the cartilage plate (Diagram II—A and B), forced movements of the annulus lamellosus might easily cause those mysterious fissures in the cartilage plate which are known to be the precursors of discal herniae. Owing to the fact that there are no nerve endings in the intervertebral disks, these minor injuries do not give rise to pain, and no opportunity is given them to repair. This seems to me to account for the fissures in the cartilage plate more satisfactorily than to imagine that the plate itself is a structure which sometimes has a congenital predisposition to premature degeneration.

DIAGRAM II

To show the origin of fissures in the cartilage plate

A, In the normal resting position. Note the fibres of the annulus lamellosus arising from the matrix of the cartilage plate.

B, Showing forcible flexion. The nucleus pulposus is pinched as a cherry-stone between finger and thumb, causing strong traction on the posterior part of the annulus lamellosus, which pulls on the cartilage plate, causing it to rupture.

1 = Cartilage plate. 2 = Nucleus pulposus. 3 = Annulus lamellous. 4 = Rent in cartilage plate.

In conclusion, I am a profound believer in Schmorl's theory, but I doubt if any but a very few cases of adolescent kyphosis are the effect of congenital causes. The key to the problem lies in those mysterious fissures in the cartilage plate which I believe arise from flexion injuries. During the rough and tumble of play any child might sustain a flexion injury sufficient to produce these fissures, but I believe that the back of a child whose hamstring muscles are short is more susceptible to traumata of this nature, particularly if his general musculature is poor on account of previous debility or over-growth. I would go even further, and say that not only do short hamstring muscles predispose to flexion injuries, but they also give rise to rotation of the vertebrae and ultimately to scoliosis. If I have succeeded in convincing you that shortening of the hamstring muscles is an important factor, then we ought to agree that children with that condition should be watched with the utmost care and intelligence at school, and that toe-touching exercises in gymnastic classes should be condemned as a routine practice.

My thanks are due to Dr. C. J. Thomas for arranging for me to examine the school children, and also to the head master and head mistresses of the Laxon Street and Snowfield Schools for their courtesy and help. I should also like to thank Dr. B. Armstrong and Mr. Seddon for allowing me to see their cases and x-ray photographs.

EFFECT OF PROLONGED ADMINISTRATION OF ACID EXTRACT OF ANTERIOR PITUITARY ON THE THYROID GLAND OF GUINEA-PIGS

BY

E. F. SCOWEN, M.B., B.S.LOND.

SECOND ASSISTANT, MEDICAL UNIT, AND BARY RESEARCH SCHOLAR,
ST. BARTHOLOMEW'S HOSPITAL, LONDON

AND

A. W. SPENCE, M.D.CAMB., M.R.C.P.LOND.

FIRST ASSISTANT, MEDICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL,
LONDON

(With Special Plate)

Aron,¹ Loeb and Friedman,² and other investigators³ have shown that the initial hyperplasia of the thyroid gland produced in animals by the administration of the thyrotropic hormone of the anterior pituitary regresses and involutes to the colloid state in spite of continued treatment. Similarly, the basal metabolism, after an initial rise to a maximum on the seventh to the fourteenth day, falls to normal or below normal (Siebert and Smith,⁴ Anderson and Collip,⁵ Friedgood⁶). The mechanism whereby this regression in thyroid activity is brought about is unknown. It has been suggested by Friedgood⁷ and by Hertz and Kranes⁸ that it may be the result of thyroid exhaustion. The present experiments were undertaken to verify previous observations and to determine whether any explanation for the thyroid involution could be found.

Experimental Procedure

The extract of anterior pituitary was prepared after the method of Loeb and Bassett.⁹ Under sterile conditions 5 grams of Armour's undegreased anterior pituitary powder were extracted with 100 c.cm. of 0.5 per cent. acetic acid for twenty-four hours at 0° C. The mixture was then centrifuged, the supernatant fluid poured off, neutralized to pH 7.8 (phenol red), and again centrifuged. The extract was prepared weekly, and, when stored at a temperature of 0° C., could be safely injected without causing sepsis. Intraperitoneal injections in daily doses of 1 c.cm. (equivalent to approximately 40 units of thyrotropic hormone) into guinea-pigs weighing about 300 grams produced in three days thyroids which were considerably enlarged, very vascular, and markedly hyperplastic (Fig. 2).

Preliminary experiments on rabbits showed that they are much less reactive to the thyrotropic hormone than guinea-pigs. Four prepubertal rabbits, each weighing about 1,500 grams and maintained on a non-goitrogenic diet of whole oats, alfalfa hay, and distilled water, received subcutaneously 4 c.cm. of the extract daily for six days. On the seventh day the thyroids were inspected surgically, and were found to be slightly enlarged and moderately vascular. The injections were continued for a further nine days and the thyroids again inspected. The glands had now diminished in size and their vascularity had considerably decreased.

Since a greater thyroid response may be obtained in guinea-pigs we chose these as experimental animals. Six males and eight females, each weighing between 300 and 400 grams, and receiving a non-goitrogenic diet containing fresh lettuce three times weekly, were given daily intraperitoneal injections of 1 c.cm., and later 2 c.cm., of the extract for varying periods up to ninety-five days. Three males and three females of approximately the same age and weight as the experimental animals were used

as controls. The guinea-pigs which received thyrotropic hormone were weighed daily, the controls twice weekly.

Results

All the animals which were injected showed an initial loss of weight. It usually fell rapidly during the first week, and then returned to the original level by the end of the second week. Thereafter it rose steadily throughout the experiment. The control animals showed a progressive increase (see Chart). Two animals, however, lost weight progressively and died, one on the twelfth day and the other on the seventeenth. On the twelfth day the latter developed exophthalmos. At necropsy no cause for death could be found. In the one which died on the twelfth day, the thyroid was extremely hyperplastic and the heart dilated. In the other, which was exophthalmic, the thyroid was slightly enlarged, but pale and translucent; microscopically there was slight hyperplasia, and colloid was beginning to accumulate in the vesicles. In both the suprarenals were enlarged and very hyperaemic.

Showing the weight curve of a representative guinea-pig receiving daily injections of anterior pituitary extract.

Exophthalmos also developed in two other animals, on the fourteenth and twenty-first days respectively, and persisted throughout the experiment (Figs. 5 and 6).

The remaining animals were killed at varying intervals. The thyroid glands of the controls ranged from 37 to 92 mg. in weight, and were histologically normal (Fig. 1). Of the twelve experimental animals the thyroid weights varied from 54 to 320 mg., and differed considerably in macroscopical and microscopical appearances. In four the thyroids were extremely hyperaemic and hyperplastic, and showed proliferative budding into the lumen of the vesicles (Fig. 3); in two the hyperplasia was less marked, and pale-staining colloid was accumulating in the vesicles. In the remaining six the glands were either pale and translucent or only slightly hyperaemic; histologically they had the characteristics of colloid glands, the vesicles being filled with well-staining colloid and the epithelium cubical or flattened (Fig. 4 and Table). In none of the thyroids was there evidence of exhaustion. The degree of thyroid involution appeared to bear no relation to the duration of treatment, neither was there any difference in the clinical appearance or behaviour of the animals which would make it possible to distinguish which animals still had hyperplastic glands. All were gaining in weight after the first week at a rate comparable with the controls.

The suprarenal glands showed marked changes. In the controls they were pale; in all the animals which received anterior pituitary extract they were enlarged and hyper-

aemic. The enlargement was greatest in those whose thyroid glands had involuted to the colloid state (see Table).

Effect of Prolonged Administration of Acid Extract of Anterior Pituitary on the Thyroid and Suprarenal Glands of Guinea-pigs

Discussion

Our results show that although the majority of the thyroids of animals receiving thyrotropic hormone over a prolonged period involute to the colloid phase, a certain percentage do not, but continue to be hyperplastic. It is unlikely that these colloid glands failed to become hyperplastic in the first place, since 100 per cent. of 150 of our guinea-pigs which have received treatment for various purposes with anterior pituitary extracts have shown marked thyroid hyperplasia.

It has been suggested, notably by Friedgood⁷ and by Hertz and Krane,⁸ that the regression of the hyperplasia is evidence of an exhaustion phenomenon in the thyroid as a result of the prolonged administration of the thyrotropic hormone. It must be stressed here that a colloid gland is not evidence of exhaustion, but is, as Marine¹⁰ has repeatedly pointed out, the nearest approach to a normal gland that a thyroid which has been previously hyperplastic can attain. Involution to the colloid phase is evidence that the thyroid is no longer working under strain. On the other hand,

"exhaustion is believed to result from sustained hyperactivity without periods of physical rest. . . . Microscopically the colloid is practically absent. The epithelial cells are in the early stages high columnar, with infoldings and plications as in the active hyperplasia. Later the cells lose their uniform and regular shape and size. . . . There is often some piling up of the epithelial cells. The nuclei are in general large, often hyperchromatic, sometimes small and pyknotic, and very irregular in size and shape. . . . The stroma is relatively, perhaps absolutely, increased, and as the follicles become smaller, due to the loss of their secreting epithelium, the fibrous bands become wider, and give to the gland the appearance of a diffuse fibrosis or cirrhosis, in

which lie the nests of distorted and degenerated cells of the former follicles" (Marine!).

The four glands in the present series which remained hyperplastic would be the most likely to show these changes, but in none of these were there any signs of exhaustion atrophy.

It can be safely concluded, therefore, that the gain in weight after the initial fall which was seen in our animals and the decrease in basal metabolism following the preliminary rise, which has been observed by other investigators to run more or less parallel with the thyroid involution, cannot be attributed to thyroid exhaustion. Some other explanation has to be sought.

Upper: showing the thyroid enlargement (weight 280 mg.) in guinea-pig No. 41, which received anterior pituitary extract daily for eighty-seven days. Lower: Thyroid gland of normal control.

Marine and Baumann^{12, 13} showed that a sufficient but sublethal injury to the suprarenal glands of rabbits produced an increase in basal metabolism, which began from the third to the sixth day, and lasted from a week to several months. This was accompanied by definite hyperplasia of the thyroid.¹³ The diminution in the size of the suprarenal cortex which occurs in infants shortly after birth was shown to be associated with a rise in metabolism.¹⁴ It is significant that in the present experiment all the animals receiving anterior pituitary extract showed marked hyperaemia and enlargement of the suprarenal glands, and that this enlargement was greatest in those animals whose thyroids had involuted. It seems probable that the suprarenals exert some control over thyroid function, since their enlargement is associated with a regression, whereas their partial removal causes an increase of thyroid activity.

The suprarenal glands appear to be dependent on the anterior lobe of the pituitary. Removal of the pituitary results in atrophy of the cortex.¹⁵ Evans *et al.*,¹⁶ and later Collip, Anderson, and Thomson,¹⁷ have shown that anterior pituitary extracts which contain the thyrotropic hormone also contain an adrenotropic principle. This adrenotropic factor was in all probability partly responsible for the suprarenal hypertrophy seen in our experiments. In addition, however, the suprarenals may also have been stimulated by an adrenotropic factor elaborated by the animal's own pituitary in response to the increased thyroid secretion produced by the administration of the thyrotropic hormone. Lastly, it is possible that an excess of thyroid secretion may directly cause suprarenal hypertrophy. This question is not yet settled; experiments are being conducted on these lines.

The demonstration by Collip and Anderson¹⁸ of the presence of an antithyrotropic principle in the serum of animals treated for a prolonged period with anterior pituitary extract containing the thyrotropic hormone is interesting. We have recently confirmed this. A rabbit, aged 8 months, was given subcutaneously 8 c.cm. of anterior pituitary extract daily for six weeks. At the

end of this period the daily subcutaneous injection of 2 c.cm. of its serum prevented the occurrence of thyroid hyperplasia in guinea-pigs receiving at the same time daily intraperitoneal injections of 1 c.cm. of anterior pituitary extract. The formation of antithyrotropic principle is probably responsible for the regression of thyroid hyperplasia in animals which have received prolonged treatment with thyrotropic hormone. It is inconceivable that an antibody be formed to a hormone, as this would render it quite useless to the organism. The finding suggests that there exists normally a balance between thyrotropic and antithyrotropic principles. If large doses of the one be given, the other is elaborated in an endeavour to bring about hormonal equilibrium. Whether this antithyrotropic principle is produced by the suprarenal cortex in response to stimulation by adrenotropic hormone also contained in the extract is as yet unknown, but, if this be so, then the adenotropic hormone may be of value in the treatment of Graves's disease.

Summary

1. Thyroid hyperplasia, exophthalmos, and suprarenal enlargement have been produced in guinea-pigs by the prolonged administration of acid extract of anterior pituitary substance.

2. Although the majority of the thyroid glands had involuted to the colloid state during treatment, a certain percentage remained hyperplastic even after ninety-three days.

3. The suprarenal enlargement was greatest in those animals whose thyroids had involuted.

4. No evidence of thyroid exhaustion was observed.

5. The production by Collip and Anderson of an antithyrotropic factor in the serum of an animal treated for a prolonged period with thyrotropic hormone has been confirmed.

6. The mechanism responsible for the thyroid involution is discussed.

We wish to thank Professor F. R. Fraser for the interest he has taken in this work. We are grateful to Mr. S. B. Bradshaw, of Armour and Company, Ltd., for generous supplies of anterior lobe powder. One of us (A. W. S.) is indebted to the Medical Research Council for personal and expenses grants.

The professorial chairs which the French Ministry of Education recently had to abolish on the grounds of economy include those of pathology and medico-chirurgical anatomy in Paris, therapeutics and external pathology at Lyons, medical physics at Nancy, operative medicine, physiology, and clinical obstetrics at Toulouse, physiology and clinical surgery at Bordeaux, pharmacy and operative medicine at Lille, and natural history and parasitology at Montpellier.

A NOTE ON THE X-RAY EXAMINATION OF EMPYEMA CAVITIES

BY

DENIS BROWNE, F.R.C.S.

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

(With Special Plate)

One of the main difficulties in the treatment of empyema is to determine the proper time at which to cease draining the cavity. At present the indications usually given for this turn upon two factors. The first is the period which has elapsed since drainage started. The time advised for drainage varies with different authors; a very widespread tradition puts it at three weeks, but it is often amazingly short, of the order of a week or so. The second indication is the character of the discharge, the tube being removed when it becomes scanty, watery in consistence, or sterile upon bacteriological examination.

Now it is to be noted that neither of these indications takes any account of the physical conditions, the size of the cavity, and the firmness of its walls. There is nothing in them to ensure against the closing up of a considerable hollow filled with varying proportions of gas and fluid. If this should occur, as it not infrequently does, the contents may fail to absorb, the pleura thickens and stiffens in its characteristic fashion, and the final obliteration of the cavity becomes extremely difficult. A persisting empyema is nearly always one in which drainage has been stopped too early and this thickening process allowed to occur.

I came to the conclusion some time ago¹ that the process of cure in all empyemata was the growing together of the walls of the abscess, with the complete permanent obliteration of the part of the pleural cavity concerned (an interesting contrast with the frequent dissolving of apparently firm adhesions of the peritoneum). In consequence, the only logical indication for ceasing drainage appeared to me to be completion of this process; otherwise it was impossible to foretell a result controlled by the unknown factors of the size of the cavity, the thickness of its walls, the nature of its contents, and the absorptive power (never very high) of the pleura. To work in this way means, of course, a renunciation of impressively quick cures, those in which drainage is successfully stopped in a week or so. I have had my share of these, but I have found their absence a small price to pay for freedom from secondary operations on those cases in which the accumulation of pus persisted.

Procedure Adopted

My first method of judging the process of healing was the crude but quite effective one of measuring the amount of fluid that the cavity would hold, running it in through the intercostal de Pezzer catheter which I employed for drainage. To the many who did not agree with me, however, this was not at all convincing, so that I sought for some more demonstrable evidence. One of the most obvious means was x rays, but their employment to define the cavity was not easy. Barium paste is difficult to get in and more difficult to get out; lipiodol is expensive, and, being a very viscous oil, breaks when in thin layers into globules that look like a charge of shot instead of giving a clean outline; and sodium iodide is liable to cause poisoning if used on an absorptive granulating surface.

In this difficulty I turned, as often before, to the head pharmacologist at the Hospital for Sick Children, Mr. Wycliffe Peck. After many experiments he succeeded in producing a cheap, sterile, stable, and very fluid

emulsion of lipiodol, which gave an admirable shadow under the x rays. By running this into the cavity through the irrigation tubes, it was possible to obtain a perfect outline of it and to follow the process of healing.

The case from which the skiagrams were taken (see Plate)—that of a large slowly healing empyema in a debilitated child of 6—illustrates the use of this method of investigation. If the time indication had been used for ceasing drainage and the tubes removed at three weeks or so after operation, I believe that a grave risk of recurrence of the abscess would have been run. The other indication, that of the nature of the discharge, would have given very little information, since throughout (probably owing to irrigation with Dakin's solution) it was thin, scanty, and almost sterile. But the x-ray examination showed steady improvement, and it was difficult in view of this to argue either for early stoppage of drainage or for later resection of one or more ribs.

The first skiagram, taken a fortnight after intercostal drainage, shows a typical large cavity in the costo-vertebral groove half filled by the emulsion. The second, six weeks later, shows the reduction of the size of the cavity by the progressive adherence of the two layers of pleura round its periphery. The spike-shaped cavity running upwards seen in the third, taken a fortnight later still, is the usual final stage of such an empyema.

I am at present trying to get the manufacturers of lipiodol to put on the market a similar emulsion to the one used. It appears to me that it should have a fairly wide application in surgery.

LEFT SUBCLAVIAN ANEURYSM IN ASSOCIATION WITH CERVICAL RIB

BY

T. G. QUINN, M.B., CH.B.,

AND

GEORGE DAVISON, M.B., B.S.

(With Special Plate)

From time to time cases of subclavian aneurysm in association with cervical rib have been reported, but the condition appears to us sufficiently rare to justify the recording of another case.

Case Report

Mrs. B., aged 75, a widow, was seen by us on November 9th, 1933, when she complained of loss of power and pain in the left arm, of three weeks' duration. Her symptoms began with a sudden loss of power in her left arm, which lasted about half an hour. Similar attacks occurred during the next few days, one attack lasting almost the whole day. Power returned to the limb, but the patient continued to have difficulty with finer movements of the hand—for example, fastening buttons. Pain, which radiated from the shoulder down the limb to the fingers, was present with the loss of power, and also passed off, leaving only a feeling of "pins and needles" in the left hand.

The patient stated that she had always been healthy. Thirty years ago, when looking in a mirror, she had noticed a pulsating swelling in the left side of her neck. This had not grown in size nor had it given her any trouble. One month previous to the onset of symptoms she had fallen on her left shoulder. As the patient was a good witness this history may be accepted.

On examination she was seen to be a well-nourished woman, who did not look her age. Above the middle of the left clavicle there was a swelling one inch in diameter, tense

and elastic in consistency, and showing well-marked expansile pulsation; the surface was smooth and the edge well defined above and below, but not medially or laterally; it was freely movable in a line at right angles to the subclavian artery, but could not be moved in the line of the artery. The overlying skin was healthy and freely movable. Compression of the subclavian artery medial to the swelling diminished the size of the latter; compression distal to it increased the tension. On slight pressure over the swelling a systolic thrill could be felt; on auscultation the aortic second sound was clearly heard. On deep palpation a bar of tissue of bony hardness could be felt behind and just medial to the swelling; this bar extended downwards and laterally from the region of the seventh cervical vertebra.

The pulse was strong in both carotid and axillary and the right brachial and radial arteries, but could not be felt in the left brachial or radial. By auscultation the blood pressure in the right brachial artery was 138/80; in the left? 120/100. In other respects the cardiovascular system appeared normal.

As regards the nervous system the only abnormality found was an impairment of the finer movements of the left hand—for example, in picking up a pin.

Her urine was normal and her Wassermann reaction negative.

Radiography showed a well-developed cervical rib on the left side and a small rudimentary cervical rib on the right. (See Special Plate.) The appearances on the left side are difficult to interpret, the outline of the first thoracic transverse process being somewhat obscure. The accessory rib appears to articulate behind with the seventh cervical transverse process and anteriorly with the first rib. It appears to us that the head of the first rib is displaced downwards and medially; and that there has also been a dislocation of the accessory rib from its articulation with the seventh cervical transverse process. There is a faint shadow present in the situation of the aneurysm.

Owing to the patient's age and the relatively unimportant disability present operation was deemed inadvisable. Yet, even in the absence of positive operation findings, we feel that the facts recorded justify a definite diagnosis of aneurysm of the third part of the left subclavian artery in association with cervical rib. The onset of the nervous symptoms may be attributed to a displacement of the first rib, and with it of the cervical rib, produced by the fall on the shoulder.

Literature

Keen¹ in 1907 stated that ten cases had been reported of cervical rib in which the symptoms suggested aneurysm of the subclavian artery, but that at operation no aneurysm was found in one case (Pancoast's) and only a flattening of the artery in a second (Murphy's). He records that in a case of cervical rib of his own he found at operation that the calibre of the subclavian artery lateral to the rib was twice that of the vessel on its medial side, but that no definite aneurysm was present. In another case (Ehrich's) aneurysm developed following operation. Keen points out that in several cases the abnormal dilatation and pulsation of the vessel disappeared following operation. He considers that true aneurysm, as distinct from temporary dilatation of the vessel, is very rare, and, in addition, warns against abnormal pulsation produced by an abnormally high position of the artery being diagnosed as aneurysm. He cites one case, however (Adam's), in which at necropsy a definite cylindrical aneurysm was found extending from the outer border of the scalenus anterior to the commencement of the brachial artery.

Halsted² has collected records of 716 cases of cervical rib, in twenty-seven or more of which aneurysm or dilatation of the subclavian artery distal to the rib was noted. These include six in which the surgeon "believed the vessel abnormally large" and two in which an aneurysm

appeared promptly after removal of the rib. In an investigation on the cause of the dilatation he performed experiments in which an artery was partially occluded by a metal band. He concludes that circumscribed dilatation of an artery may arise distal to a constriction, the dilatation being at a maximum when the lumen of the vessel is reduced to a third or a quarter; and that it is constriction of the subclavian artery which produces the dilatation sometimes noted distal to a cervical rib. The portion of the artery distal to the constriction forms a relatively dead pocket, and, in his opinion, the dilatation is probably due to the whirlpool-like play of blood in this. He believes that probably vasomotor paralysis, trauma, and sudden variations in the blood pressure in the artery play no part. Halsted does not distinguish simple dilatation of the artery and "true aneurysm."

Since Halsted's article at least two further cases have been reported.

Moore² records a case in a man of 55 in which there was a saccular aneurysm the size of a cherry springing from the anterior surface of the artery just distal to the rib. There was neither bruit nor thrill over the aneurysm, it was increasing in size, and there was no difference in the radial pulses. The Wassermann reaction was strongly positive. Good recovery followed ligation of the artery on either side of the aneurysm.

Billington⁴ describes a patient of 42 who came under observation with a pulsating swelling in the left side of the neck; there was a difference in timing of the radial pulses. One month later the left radial pulse had disappeared and pain was severe. After a further five months the pulsation in the swelling had gone. There were no nervous signs. X-ray showed a fully developed cervical rib on the right side and an incomplete rib on the left. The Wassermann reaction was negative. The patient made an uneventful recovery following excision of the aneurysm. The aneurysm consisted of a fusiform swelling $2\frac{1}{2}$ in. in length and with a maximum diameter of $\frac{3}{4}$ in. It was almost completely occluded by thrombus. No primary disease of the intima was found.

Discussion

It appears to us that Moore's case was of a different nature from the others, and produced by different factors; the aneurysm was saccular in character and not associated with a difference in the radial pulses, and there was evidence of a syphilitic infection.

The case we have described seems to fall into line with the others recorded and with Halsted's experimental results—that is, there is a circumscribed dilatation of the subclavian artery immediately distal to a constriction caused by a cervical rib. We shall not attempt to define the conditions under which the dilatation of an artery shall be termed aneurysmal, but maintain that, clinically at least, the swelling in our case is an aneurysm of the third part of the subclavian artery. It is worthy of note that this aneurysm had evidently been present for thirty years without enlargement and without symptoms.

Summary

A case has been described of left subclavian aneurysm in association with cervical rib. The aneurysm had been present for at least thirty years, but neither it nor the rib had produced any symptoms until a fall on the shoulder caused a displacement of the rib.

We are indebted to Dr. Whately Davidson of Newcastle-on-Tyne for the radiograms of the case.

A CASE OF BLINDNESS AFTER N.A.B.*

BY

FRANK JULER, F.R.C.S.

OPHTHALMIC SURGEON AND LECTURER IN OPHTHALMOLOGY,
ST. MARY'S HOSPITAL

The organic preparations of arsenic used medicinally are divisible into two groups—the pentavalent and the trivalent. The former derives from arylarsinic acid and comprises atoxyl, soamin, arsacetin, hectine, orsudan, indarsol, stovarsol, treparsol, and tryparsamide. The trivalent group obtains from arsenobenzene, and contains salvarsan and its allies. The synonyms of salvarsan are "606," arsenobillon, arsenobenzol (France), and arspenamine (U.S.A.). Similarly, neosalvarsan is known as "914," N.A.B. (novarsenobillon), novarsenobenzol (France), and neoarsphenamine (U.S.A.).

Cases of blindness after administration of the pentavalent group were early recognized, and were collected by Lawford in a paper opening a discussion in 1916 (*Trans. Ophth. Soc.*, vol. xxxvi, p. 12). He mentioned cases of blindness following atoxyl reported by Koch, Kopke, Morax, and McAdams. In 1910 Ernest Clarke (*ibid.*, vol. xxx, p. 240) reported blindness after soamin and orsudan; and it is known to occur after stovarsol and treparsol. Tryparsamide is a drug which has been in use recently for neural syphilis and trypanosomiasis (Lees, *ibid.*, vol. lli, p. 208), but there is an admitted danger of optic atrophy, and its administration calls for care, especially during the first few injections. (See also Woods and Moore, *Journ. Amer. Med. Assoc.*, vol. lxxxv, p. 329).

Reports in the Literature

With regard to the trivalent arsenical preparations, the report of the Salvarsan Committee of the Medical Research Council in 1922 (Special Report No. 66) includes a section on the toxic effects of these drugs. It refers to an enormous amount of material from military hospitals and civil treatment centres. Altogether 140,636 cases are included, and no blindness was reported, although there were forty-nine fatalities. German figures are also mentioned. In 1914, 74,018 German cases were reported, including one in which blindness resulted. Further German figures in 1917 referred to 265,158 cases without any blindness. Thus, in a grand total of 479,812 cases, only one case of blindness was reported after the use of the salvarsan group.

In 1916 Lawford stated (*loc. cit.*, p. 25):

"After '606,' optic nerve lesions and lesions of the third, seventh, and eighth nerves have often occurred, which develop from a few days to six weeks after the injection. These usually, but not invariably, disappear if further treatment by '606' or mercury is adopted. These lesions are undoubtedly syphilitic, but are precipitated by salvarsan."

In 1927 J. G. Hopkins wrote (*Amer. Arch. of Ophthalm.*, vol. lvi, p. 543):

"The production of optic atrophy by arspenamine in a previously uninjured eye has never been proved, but with a pre-existing neuritis of primary optic atrophy, it may appear to cause damage."

In 1928 S. O. Chambers also reviewed the literature, and finds that reports of damage to the eye from salvarsan are very rare (*ibid.*, vol. lvii, p. 412). In 1930 Dr. Gunn said that the trivalent preparations did not cause amblyopia (*Trans. Ophth. Soc.*, vol. i, p. 392). In 1931 E. A. Seale (*Journ. Med. Assoc. of South Africa*, p. 528) reported the case of a man, aged 54, who

* Read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

lost vision after a first injection of 0.75 gram of N.A.B. Three more similar doses were given without further effect. The vision was reduced to 1/60 in each eye, with white sharp-edged disks and narrowed vessels. The field to white was full; that to colour was lost. Two months later it had improved so that the right vision was 3/60, the left 6/60.

Case Record

The case I have to report is as follows:

History and State.—A married woman, aged 46, was brought to hospital on account of a positive Wassermann reaction. She was admitted with a history of some mental abnormality (? nervous debility), two miscarriages, and several attacks of aphonia. She had undergone appendicectomy and removal of gallstones seven years previously. On admission she was found to have an aortic systolic murmur, but there was no complaint of vision, and her mental and general condition appeared good. She had had no eye trouble previously.

Treatment and Progress.—She was given a course of N.A.B. by the resident medical officer in six doses, commencing with 0.3 gram and concluding with 0.9 gram twenty-eight days later. (The dates and doses are recorded as follows, but there is some doubt as to their exactitude: first day, 0.3 gram; fourth day, 0.45 gram; eleventh day, 0.5 gram; sixteenth day, 0.6 gram; eighteenth day, 0.75 gram; twenty-ninth day, 0.9 gram.) She was also given mist. hydrarg. biniodidi by mouth. She developed a skin rash on the day after the last injection. Fifteen days later she became rapidly blind in both eyes, the left lost all perception of light, the right vision was reduced to hand movements. I saw her two days later and noted that both disks were white, with slightly hazy outlines, and that the arteries were narrow, with white lines along them. The vision varied but little afterwards, and two years later she still had no perception of light in the left, and bare perception of light in the right eye. The disks were white with hazy edges; some of the vessels were small, some of fair size.

Outcome.—Her general condition remained fair at the time of the onset of blindness; she was in a somewhat toxic state, but there was no encephalitis and no meningitis. The rash noted previously had subsided. The cerebro-spinal fluid was not examined. Trinitrin was administered on the day after the onset of the blindness, and a few days later sodium thio-sulphate was given intravenously, but without benefit. The Wassermann reaction and the Kahn tests were still positive two months later.

Commentary

The rarity of this complication renders the above account open to criticism, but the facts are as they have been recorded. The woman was admitted with no ocular complaint; she became blind. There is no doubt but that she was treated with N.A.B., but the exact dates and doses cannot be vouched for. The dimness of vision affected both eyes simultaneously and was rapid in its onset. There was no gross oedema of the disks, and the whole appearance seems to resemble that seen in quinine poisoning in the optic pallor and narrowing of the vessels of the retina.

In the report of the special committee of the Medical Research Council the opinion is expressed that some ill effects of salvarsan are due to inorganic arsenic (a capillary poison), which is slowly broken down after injection, and the late action is thus explained. The reactions of salvarsan are classified as follows: (1) immediate—for example, diarrhoea, vomiting, fever, and headache; (2) encephalitis haemorrhagica—two to five days later; (3) liver affections—(a) jaundice, early and transient, or (b) jaundice, occurring several weeks after the end of the course of treatment, and running a long period, (c) acute yellow atrophy; (4) exfoliative dermatitis, which may be late, and may be fatal from septicaemia; (5) rare lesions—for example, acute nephritis, enteritis, polyneuritis, and aplastic anaemia; and finally,

(6) the Hershheimer reactions, from relapse of syphilis, owing to a sudden liberation of spirochaetal toxins. (These include nerve lesions, especially the cranial nerves, and are more likely to affect structures which have already been attacked by the disease. Such reactions may start after the first injection or after the end of a series.)

In the present instance the pathological site and mechanism are open to discussion. As far as was known there was no gumma or other gross lesion present, the solution of whose walls might set free spirochaetal toxins to attack the optic nerve. It would seem that it is more likely to have been a case where the arsenic itself has affected the optic nerve, the retina, or its blood vessels.

Clinical Memoranda

THE USE OF FASCIA LATA SUTURES

The particular method of obtaining a fascia lata strip is decided by two factors—namely, the difficulty or ease of the method and the after-effects on the patient. Leading authorities insist on the need of closing the gap left in the fascia lata after removing the strip, and this, of course, necessitates a skin incision corresponding in length to the length of the fascial strip obtained. Gallie and Le Mesurier¹ say that failure to close this gap results in "mild bulging muscle hernia, and some of these people speak of a feeling of moderate weakness in the thigh." Orrin² says that omission to close the gap "bequeaths to the patient a heritage or soreness, an aching, and a constant tiredness in the area and in the limb, and so impairs, in greater or less degree, the usefulness of the limb itself." In face of such authority it was with some trepidation that I employed for a small series of cases of hernia a fascial strip cut subcutaneously through small incisions in the thigh. This leaves, of course, the gap in the fascia lata unsutured, but the saving in time and trouble over suturing the gap in fascia and skin is considerable.

TECHNIQUE

The instrument used was that described by Lane and Austin,³ and known as the "Meath Hospital fascia cutter." It consists of a handle bearing a long rod, at the end of which is a strip with a knife-edge bent into a U shape. This cutting strip is introduced through a small skin incision into two small cuts in the fascia lata, marking out the width of fascial strip desired. Pushing the handle along then results in this strip being separated from the rest of the fascia on each side. It is claimed that the strip of fascia may be cut through the one small incision, the instrument being designed so that a turn of the handle cuts across the fascial strip at any desired length.

In actual practice two modifications will be found to save time. First, the overlying skin is bound down to the fascia lata by tough bands of fibrous tissue, and these should first be broken down and the skin and fascia separated over the area from which the strip is to be taken. This is best done by using the spatula-like handle of the fasciotome invented by Rowlands. The fascia separates easily from the underlying muscle as it is cut. Secondly, it will be found easier to cut the strip across at the upper end under direct vision through a second small incision.

RESULTS

I have traced twenty-five of my cases and examined them at intervals of from three and a half months to two years after operation. This number is small, but

¹ Gallie, W. E., and Le Mesurier, A. B.: *Canadian Med Assoc. Journ.*, August, 1930, p. 165.

² Orrin, H. C.: *Fascial Grafting in Principle and Practice*, 1928, p. 33.

³ Lane, T. J. D., and Austin, T. A.: *Lancet*, 1930, i, 622.

I felt some reluctance to use a method not approved of by leading authorities. The number is large enough, however, to allow some conclusions about the method to be drawn. All of the patients had a muscle hernia through the gap left unsutured. No one complained of weakness, and some were following the strenuous occupation of dock labouring. Twenty did not complain of any pain; the other five said they had occasional slight pain. So that, using this method, we may expect a muscle hernia in every case, no muscular weakness in any, and some slight pain in a few. The incidence of pain is probably no greater than would occur if a long skin incision had been used.

Whether a muscle hernia can be prevented is doubtful, even if the gap is sutured. Gallie and Le Mesurier⁴ have themselves shown that aponeurotic structures, no matter how they are sutured together, will separate if the line of suture is subject to strain, and they conclude that "edge-to-edge suture of aponeurosis or fascia should only be done where the tissues can be brought together without tension, and where the physiological strain will be slight." The strain on a suture line in the fascia lata when a portion has been removed must be frequent and considerable.

CONCLUSIONS

1. Fascia lata strips are most easily obtained by the subcutaneous method.
2. No serious after-effects result from this method.

My thanks are due to Dr. H. H. MacWilliam, medical officer of Walton Hospital, Liverpool, where these cases occurred, for permission to publish the results.

Honorary Assistant Surgeon, District Infirmary,
Ashton-under-Lyne.

DIABETIC GANGRENE IN A YOUNG WOMAN

It has been suggested to me by Dr. R. D. Lawrence that the following notes on diabetic gangrene in a girl 20 years of age may be interesting to some of your readers.

The patient, a confectioner, was first admitted to the Royal Lancaster Infirmary on May 8th, 1932. It seemed that her illness had commenced two weeks previously, with a feeling of malaise, dizziness, and vomiting. Her medical attendant, on finding glycosuria, immediately sent her into hospital. On admission she was very thirsty, dyspnoic, and the breath smelt strongly of acetone. Urine showed sugar ++++; blood sugar was 0.4 per cent. Under insulin the blood sugar came down, and she was discharged on a 1,700 calorie diet, with instructions to attend periodically for blood sugar estimations.

On December 4th, 1933, she was again admitted to the Infirmary, where she arrived in a comatose condition: urine—sugar +++, acetone +. Twenty units of insulin three times a day made the urine sugar-free and brought the blood sugar to 0.2 per cent. On 40 units a day she became sugar-free for a short time, but the dose had to be increased to 45, and finally to 50 units. She was discharged on December 16th with instructions as before, which unfortunately she failed to observe. She was exceedingly difficult to stabilize.

The patient was readmitted to the Infirmary on July 23rd, 1934, with the following history. She had been quite well until one week before, when, after bathing in the sea, she complained of chilliness and a feeling of numbness in both feet. Next day she had a severe headache, and went to bed. Two days later she developed a cold, and complained of severe malaise and a pain in the right chest. The numbness of the feet had now passed off and the malaise had subsided, but the left foot became distinctly blue, with complete loss of sensation.

On examination she was markedly dyspnoic, and the breath smelt strongly of acetone. Chest signs were those of the early stages of pneumonia. The left foot was cold and completely anaesthetic up to two inches above the malleoli. There was gangrene of all the toes for about one inch on to the dorsum.

Pulsation was absent in the popliteal, posterior tibial, and dorsalis pedis arteries: knee-jerks were present. The right foot was also cold and white, with no pulsation to be detected in the dorsalis pedis artery. The following day the gangrene in the left foot had extended considerably, and had reached the middle of the dorsum. The toes of the right foot had now become blue. A definite consolidation was present in both lungs; the patient gradually became weaker, and died on July 28th.

I wish to acknowledge my indebtedness to Sister Selkirk, who in the earlier treatment of the case was in charge of the ward, and to Dr. Kenneth Tattersall, senior house-surgeon, for his notes on the later stages.

F. W. BURY, M.D.,
Honorary Physician, Royal Lancaster
Infirmary.

THE SWALLOWING OF OPEN SAFETY-PINS

I think it may be instructive to record two cases of very young children who swallowed open safety-pins. Both were admitted to the Victoria Central Hospital, Wallasey.

The more recent case was that of a child of 2 years. The pin stuck behind the cricoid, and the child was admitted crying and in pain, with its hand held over its mouth. It resolutely refused to swallow anything, no doubt because of the pain that any effort of deglutition caused. The child had been very sick after swallowing the pin, but without returning the foreign body.

The oesophagoscope was passed without any anaesthetic, local or general. The intention was to try and draw the pointed shaft into the oesophagoscope, and, having got it thus out of harm's way, to withdraw both pin and tube together. This could not be done. The keeper of the safety-pin was immediately found at the cricoid level, but the pointed shaft could not be seen even after prolonged search. As traction on the keeper would have drawn the point into the tissues, and the pointed shaft could not be found, I had no choice but to free the pin and try and work it into the stomach. I did not find this easy, but eventually I lost sight of the pin, and concluded it was probably in the stomach.

A little haemorrhage, however, made it difficult thoroughly to search the lower end of the oesophagus, and I was not very surprised, therefore, to find, on taking a further radiograph, that the pin was arrested at the cardiac opening of the oesophagus. The child could now, however, swallow fluids easily, and the pin was soon carried into the stomach, where it remained about two days. It subsequently travelled slowly and uneventfully downwards, and was voided on the sixth day.

As soon as the pin had been dislodged from the cricoid region, and the child was able to swallow, cotton-wool was given in the food and drink. The wool was teased into tiny pieces about the size and thickness of confetti, and freely mixed with the meals. Unless it is in very small pieces wool is easily detected in the food, and young children will extrude it from the mouth. Ordinary food was given and no aperient allowed. When found in the motion the pin was completely enveloped in wool. No particle of metal was discernible, and it was necessary to tear away the woolly covering to be sure the pin was within. The pin was 1½ inches long, and the span at the open end was 5/6 of an inch.

A very similar case was in the same ward a short time ago. In this instance the child was 3 years old, and the pin was not caught in the oesophagus. It was rather a larger pin, about 1½ inches long, with a wide gap at the open end. Cotton-wool was given in the same way, and the pin was voided completely enclosed in a woollen envelope.

The chief conclusions to be drawn from these cases are: (1) if an open safety-pin will pass through the oesophagus there is a good prospect of it making a safe journey through the whole alimentary canal; (2) the mixing of wool in the food will, certainly in many cases, cause the pin to become completely embedded in a matted cocoon-like covering.

Reviews

PRACTICAL ASPECTS OF ALLERGY

In *Allergy in General Practice*¹ Dr. S. M. FEINBERG has produced an account of the subject which is refreshing. Many books have been published in recent years on the subject of allergy, and it is difficult as yet to assess their relative merits. But it can be stated with confidence that this book is essentially practical, and the author has no particular theory to exploit. It is written with the object of enabling the medical practitioner to diagnose and treat a case of allergy with understanding, and this object is largely attained; it is not, and does not claim to be, a book for the research worker.

There are sections on the history of our conception of allergy and anaphylaxis, on the pathology, symptoms, and complications of asthma. The specific causes of asthma are adequately discussed, and the diagnosis and treatment of asthma are dealt with in detail; hay fever and its treatment also receive due attention. The account of the American pollens naturally will be of less value to European readers, but the principles underlying the conventional treatment of hay fever are clearly stated. A chapter is devoted to other allergic and possible allergic diseases, and is of interest in that the author does not overstate his case, and yet discusses such debatable subjects as the justification for including migraine and epilepsy in this group. The book concludes with an interesting series of case histories taken from the author's own experience, which should be a help to others in the management of similar cases.

The impartiality of Dr. Feinberg's judgement may be illustrated by the following quotation, in which he is discussing the nature of the asthmatic constitution:

"We may summarize by saying that of all the concepts explaining the constitution of the allergic individual there is no evidence for many, some evidence but no proof for some of them, and no absolute proof for any one of them. And yet there must be an allergic constitution!"

This attitude of the author adds greatly to the attraction of the book, as the limitations of our knowledge both of the causation and of the treatment of asthma and allied diseases is made manifest. This is a sound book, well printed, and should prove of value to anyone interested in the subject, especially from the practical point of view.

PROBLEMS OF DUST

The interesting and instructive monograph on *Dust*² by Dr. CYRIL BLACKTIN commends itself to meteorologists and students of the physical sciences and of problems of public health. The widespread distribution of dust on the earth's surface, and its diffusion through the atmosphere, give to the subject an importance which cannot be ignored. Dust, as the end-product of material degradation, assumes various forms consequent upon the attritional influence of physical forces upon the earth's surface, of chemical actions, and of industrial operations. It is composed of visible and invisible particles of matter, in such a fine state of subdivision that the particles are light enough to be easily raised, and carried as a cloud, by the wind. A diameter of 50 microns is the dividing line between visible and invisible units in the atmosphere. Once formed the tendency is for dust particles to decrease in size. It is the invisible particles which are the more important. Clear air may contain as many as 30,000 to

60,000 particles per cubic centimetre, which the ordinary tests of visibility might not affirm. Dust accumulates in certain territorial areas more than in others, so that the material is raised as sand-storms in the deserts or carried as snow-dust clouds over mountains, while in its minor quantities it is raised in the streets of towns by vehicular traffic, and in factories by the feet of the workers, the wear and tear of machinery, and the escape of products of manufacture in fine division. Instead of using the phrase "a dust-laden atmosphere" the author suggests the word "staubosphere" for the aerial surrounding medium which is coextensive and coexistent with the earth's atmosphere.

The question has on several occasions been asked as to how far, in the first instance, life was conveyed to the earth by clouds of meteoric dust, how far dust is of cosmic origin and the outcome of meteoric disintegration; but these questions need not detain us. It is enough for us to know that it plays an important part in mundane phenomena by precipitating rainfall, and by obstructing the penetration earthwards of certain of the sun's rays. Particles of dust contain solid nuclei, which are water-soluble or insoluble. The nuclei of city carbon dusts are mostly insoluble. Rain surrounds dust particles with a watery envelope, and, in falling, it depletes the atmosphere of solid particles. The liquid evaporating on the settlement, the solid particles remain. These are subsequently lifted by the wind and carried hither and thither, deposited in fresh areas, or wafted into the streams and carried seawards. Dust by facilitating rainfall clears and cleans the atmosphere, but in the neighbourhood of smoke-laden cities and industrial works, where the nuclei of the dust particles are carbonaceous or metallic, and the surroundings are soiled, rainfall will temporarily increase the dirtiness. Rain may contain slightly dissolved gases, and while it is pure when falling in remote country areas it cannot, in towns, for long remain thus. Dust is a medium for the conveyance of bacteria by adhesion. Polar air is free from micro-organisms; so, too, may be the hot air of the desert, although rich in dust. Ocean air is remarkably free from bacteria, partly owing to the large number of salt particles of which it is the bearer.

In the ordinary walks of life we cannot escape from dust, visible and invisible. In addition to dust raised in the streets as the result of traffic, the air we breathe is polluted with smoke from chimneys and the debris given off from the rubber tyres of motor cars and lorries. Dr. J. T. Dunn and Mr. H. C. L. Bloxam have drawn attention to the possible injury to health by exhaust particles escaping from motors. Analysing dust collected in the streets of Newcastle-upon-Tyne and grasses growing on roadsides leading to and from that city and much frequented by motor vehicles, these analytical chemists found lead and copper to the extent of 6.5 parts per million. The wearing down by friction of tramway and railway lines, also the chemical corrosion of exposed iron structures, not only impregnate the atmosphere with metallic dust, but are a serious economic loss to the country. A distinction is made between smoke and dust. Smoke particles are primarily large: they increase in size and agglomerate: later, ceasing to increase further in size, they disintegrate and become dust. There is, therefore, a continuous transition from smoke to dust, but never vice versa. Without dust, light itself would be invisible. It is the presence of dust which confers upon the sky its colour.

Dealing with dust in industry and technology the author divides dust into two types—nuisance and dangerous. The former is that found on the floors of factories and smithies, and in the neighbourhood of disintegrating colliery spill heaps: dangerous dusts, on the other hand,

¹ *Allergy in General Practice*. By Samuel M. Feinberg, M.D., F.A.C.P. London: H. Kimpton, 1934. (Pp. 339; 23 figures, 1 coloured plate. 21s. net.)

² *Dust*. By Cyril Blacktin, M.Sc., Ph.D., A.I.C. London: Chapman and Hall, 1934. (Pp. 296; illustrated. 15s. net.)

are those which are capable of inflicting considerable damage physically, for if disseminated through the aerial medium of a coal mine, for example, they create a highly combustible dust-laden atmosphere, capable of becoming ignited by an electrical spark and causing an explosion. Of all dusts that evolved from coal is the most dangerous, owing to its combustibility, the extent of its production, and the readiness with which it is fired and exploded in the presence of methane and hydrogen-air mixtures.

The earliest treatise dealing with metallic dust is, according to Blacktin, *De re Metallica*, by G. Agricola, published in 1556, several decades before Ramazzini was born. Since then the study of the subject has grown apace. It is not that dust alone is always the harmful agent to persons employed in industrial occupations, so much as that the particles are carriers of microbes. For over a century and a half the medical profession has been familiar with the harmfulness of the metallic dusts of industries and of mining. Mineral rocks rich in silica are the main sources of the lung diseases which affect rock-drillers, hence the term "silicosis." Silica and silicate dusts, when inhaled, stimulate the phagocytic activity of the large cells in the alveoli of the lungs. Industrial dusts may be swallowed or inhaled, but the principal and more dangerous portal of entry is the respiratory tract. When inhaled the particles may cause irritation of the tracheal and bronchial mucous membrane, and, by recurrent bronchial catarrh, a denudation of their protective mucous membrane, so that the finest particles of dust readily reach the alveoli of the lungs, and while many of these particles are phagocytosed and eliminated by expectoration, others of the dust-laden cells are retained in the alveoli, pass into the lymphatics, and are carried to and deposited in the glands at the roots of the lungs, while simultaneously the interstitial tissue of the pulmonary parenchyma is becoming overgrown and fibrotic. Dust diseases of the lungs have been so fully dealt with in the pages of this *Journal* that there is no call to consider now the symptomatology and pathology of the pneumoconioses. *Dust*, by Blacktin, is a wealth of carefully collected data; it bears the imprint of wide reading and of a discriminating personality.

TREATMENT OF SPASTIC PARAPLEGIA

Mrs. MARGUERITE K. FISCHEL records in *The Spastic Child*³ her experiences in the training of her paraplegic son, and shows what in a suitable case may be achieved by unremitting maternal devotion and paediatric skill. This record would have pleased William John Little, to whose work Mrs. Fischel refers, for he insisted strongly on the importance, even in apparently hopeless cases, of frequent manipulations and training directed to the overcoming of spasm and acquisition of muscular control. No exact account is given in this book of the extent or degree of spasm in the case in question, but we must infer from the results attained that the higher cerebral centres were not seriously affected, but that the disease affected only the spinal cord.

In this little book Mrs. Fischel describes the exercises and manipulations which, during sixteen years, were with unflinching perseverance carried out by her and her son with astonishing results. No surgical operation was performed and no orthopaedic appliance was found necessary, except for the treatment of an intercurrent compound fracture of the femur, the result of a motor car accident. Mrs. Fischel informs us that the boy's father, who is a surgeon, nevertheless took no part in the treatment here described.

³ *The Spastic Child. A Record of Successfully Achieved Muscle Control in Little's Disease.* By Marguerite K. Fischel. London: H. Kimpton. 1934. (Pp. 97; illustrated. 6s. net.)

MILTON'S BLINDNESS

To the perennial subject of Milton's blindness Miss ELEANOR BROWN has added a contribution of an intensely personal character,⁴ for her interpretation of Milton's life and writings is based on her own experience of blindness since childhood. On many points generally accepted by the sighted critic she differs considerably, drawing on the emotional reactions of the blind to emphasize her arguments. Most critics would agree with the estimate Rose Macaulay gave in her recent study of Milton that "he died a vanquished and embittered idealist, in a world with which he had never come to terms, nor could." It is also generally accepted that *Samson Agonistes* is almost a crypto-autobiography, in which the vanquished and embittered idealist wreaks imaginary vengeance on his enemies. There are also those who see autobiographical references in every mention of blindness in Milton's writings. With all this Miss Brown breaks radically. She argues persuasively that Milton was at peace with the world; that though he passed through a stage of agony during the development of his blindness, he had reached a serene resignation by the time he penned his sonnets on the subject; that he was complete master of his soul when he wrote *Paradise Lost*; and that so far from being autobiographical, *Samson Agonistes* with its complaints on blindness is the least autobiographical of Milton's writings, for the emotions portrayed are wholly at variance with the dispassionate resignation apparent elsewhere. She definitely makes a strong point in saying that his pride would never have allowed Milton to lament his blindness in the stark nakedness of *Samson's* complaints, and that anyhow Milton would not have given his enemies the satisfaction of such complaints. Miss Brown's view of Milton certainly conjures up a happier man, but one cannot help feeling that Milton was a more dynamic character and less at ease amongst men than the nice old gentleman that emerges from her studies.

The opening chapters of this able and very interesting study are devoted to a discussion on the nature of the poet's blindness. The author rightly dismisses the absurd view of Saurat that congenital syphilis was the cause, and Mutschmann's still more preposterous theory of albinism. Between the two possible causes—glaucoma, as held by W. H. Wilmer, and myopia with detachment, as argued by Arnold Sorsby—Miss Brown, like the wise critic she is, refuses to adjudicate.

WILDBOLZ'S TEXTBOOK OF UROLOGY

Anyone who has read Professor HANS WILDBOLZ's textbook of urology will rejoice at the appearance of a second edition.⁵ The original work was, in the reviewer's opinion, the best of the smaller textbooks on the subject, and the new edition is even better than the old. About one hundred pages of new matter and fifty illustrations have been added, yet all the good points of the original have been retained. Among the additions are a chapter on Bright's disease, which, the author mentions in his preface, has been made at the request of many readers, and an account of gonorrhoea in the male. The inclusion of the former in a work that is otherwise entirely surgical may be open to question, but there can be no doubt that the latter subject should be incorporated in a work on diseases of the urinary organs in both sexes, and of the genital apparatus of the male. These two additions account for about half the new matter, the remainder

⁴ *Milton's Blindness.* By Eleanor Gertrude Brown. New York: Columbia University Press; London: H. Milford, Oxford University Press. 1934. (Pp. 167. 12s. 6d. net.)

⁵ *Lehrbuch der Urologie.* Von Professor Hans Wildbolz. Zweite Auflage. Berlin: J. Springer. 1934. (Pp. 645; 218 figures. R.M. 64; geb., R.M. 68.)

being interpolations necessary to bring the book up to date.

The great charm of Professor Wildbolz's book, which applies to all his writing, is that he has the happy knack of making his meaning perfectly clear. There is never the slightest ambiguity in his statements. Moreover, his style is simple and his sentences short. The book can therefore be read easily by anyone with a limited knowledge of German, and can be recommended to those who wish to gain facility in reading medical literature in that language.

The book is divided into two parts. The first deals with the physical examination of the patient, the examination of the urine, cystoscopy, catheterization of the ureters, estimation of the renal function, and radiography of the urinary tract. It concludes with a chapter on general symptomatology—pain, changes in micturition, pathological conditions of the urine, urinary fever, etc. The second part, by far the longer of the two, is purely clinical, and is divided into sections according to the organ affected. The pathology and symptomatology of the different diseases are fully described. The operative methods are given in less detail, but their modifications to meet special conditions are carefully considered. The teaching is extremely practical, and is the result of great experience.

On the whole, the book is crammed with sound, useful information. There is no repetition or unnecessary verbiage. Although the matter in it is condensed, it is set forth in an interesting and readable form. There is only one fault to be found with it. The book, like many other German works, is too expensive. A paper-covered volume of less than 650 pages should not cost 64 marks. At the present rate of exchange this is approximately £5.

Notes on Books

A second edition has now been issued of *The Practice of Absorption Spectrophotometry with Hilger Instruments*,⁶ by Mr. F. TWYMAN and Dr. C. B. ALLSOPP. The subtitle of this book gives a sufficient indication of its scope—"An introduction to the theory of the subject, and guide to the technique of absorption measurement in the visible, ultra-violet, and infra-red regions of the spectrum."

Of the five articles in the September number of the *Annals of Medical History* two deal with European and three with American medical history. In an extremely complete account of Sir Dominic Corrigan and the water-hammer pulse, Professor George Dock, formerly of Washington University, St. Louis, now of Pasadena, who has written similar interesting footnotes to medical history, traces the origin of the familiar descriptive name "water-hammer pulse." It did not appear in Corrigan's original article in 1832; after a long search, in which for a time the earliest use appeared to be in an article by Galabin in 1876, it was found that another Guy's physician, Hilario Barlow, had in 1852 written about "the splashing or water-hammer pulse," and that Sir Thomas Watson may have anticipated him. At one time, like Sir Dyce Duckworth at St. Bartholomew's Hospital, Professor Dock always showed his students the water-hammer toy, but in 1915 he could no longer obtain one. Dr. W. T. Dempster of Ann Arbor completes his well-illustrated account of European anatomy before Vesalius, which he began in the July number of the *Annals*; he points out

⁶ *The Practice of Absorption Spectrophotometry with Hilger Instruments*. By F. Twyman, F.Inst.P., F.R.S., and C. B. Allsopp, M.A., Ph.D. Second edition. London: Adam Hilger Ltd. 1934. (Pp. 140; 40 figures. 12s. 6d. net.)

⁷ *Annals of Medical History*. New Series, vol. vi, No. 5, September, 1934. Edited by Francis R. Packard, M.D. New York: Paul B. Hoeber, Inc.; London: Baillière, Tindall and Cox. (Pp. 381-474; illustrated. Volume of six numbers, £2 15s.; single number, 12s. 6d.)

that with the exception of Leonardo da Vinci the serious-minded anatomists lacked the insight and appreciation of method which in succeeding centuries raised anatomy from a colourless discipline to a vigorous science. Dr. W. B. Howell of Montreal tells the story of the Hôtel-Dieu of Quebec, from its start as a small log cabin in 1639, with six nuns from the ancient Hôtel-Dieu at Dieppe to the present great teaching hospital, and relates how in the interval it has played its part in many troubles, including great epidemics of cholera and other infections a hundred years ago. Dr. Jonathan Forman of Columbus, Ohio, tells in detail the history of the first cholera epidemic in that town in 1833; and Dr. A. E. Fossier continues and concludes his history of medical education in New Orleans.

The August issue of *Arquivos de Medicina Legal e Identificação*⁸ is devoted to the proceedings of the Congress of Identification organized by the chiefs of the police of the Federal District of Brazil and of São Paulo, held at Rio de Janeiro from June 16th to 23rd, under the presidency of Professor L. R. Almandos of the University of La Plata. The issue is illustrated by portraits of the leading personalities of the congress and numerous photographs of the São Paulo Institute of Identification.

⁸ *Arquivos de Medicina Legal e Identificação*. Edited by Leonido Ribeiro. Rio de Janeiro: Imprensa Nacional. 1934. (Pp. 242; illustrated.)

Preparations and Appliances

WELLCOME INSULIN (CRYST.)

We have received a sample of Wellcome Brand Insulin (cryst.), which the makers (Messrs. Burroughs Wellcome and Co.) state is the first commercial insulin made from pure crystalline insulin. This is an interesting advance in the chemistry of endocrine products, and it is satisfactory to note that the price for the highly purified product is only 2s. 3d. per 100 units.

RHINITOL

Rhinitol is a preparation for nasal administration. It contains a mixture of volatile oils, together with ephedrine; they are dissolved in a vehicle which is stated to be an advance on ordinary liquid paraffin. The preparation has an antiseptic and vaso-constrictor action, and is recommended for use in a variety of forms of nasal infection. It is manufactured by E. T. Pearson and Co., Ltd., London Road, Mitcham.

"ALLENBURY'S" PRODUCTS

Allen and Hanburys Ltd. are putting two new preparations on the market. One is "Allenbury's" tannic acid jelly, a water-soluble antiseptic application containing 2.5 per cent. of tannic acid ready for immediate use in the treatment of burns; free from oil or grease—price 1s. 9d. a tube. The other preparation is "ferrédis" iron granules—chocolate-flavoured granules containing 1.75 per cent. of ferrous iron in glucose, suitable for children and adults—prices 2s. 3d. and 4s.

POCKET REFRACTOMETER

Bellingham and Stanley Ltd., 71, Hornsey Rise, N.19, announce the production of a pocket refractometer, primarily designed for the direct reading of the percentage of sugar in solutions. This instrument covers a range of from 0 to 25 per cent., and has a sufficiently open scale to allow of estimations down to 0.1 per cent. It is thought that it may have important uses in medical work for blood and urine estimations. Following in design that of the larger instruments, it consists of two glass prisms mounted in a hinged box. A drop of the liquid to be tested is placed between, and readings are made by an orthodox optical system upon a scale divided from 0 to 25 per cent. soluble solids. The refractometer is sent out correctly adjusted, with a check reading for water of 0 at 20°C. Three types of instrument are offered, and certain other ranges are available to suit special purposes. The overall length is 16 cm.; weight, 112 grams. Prices vary from £5 10s. to £6 10s.

LA GRANULIE FROIDE

Nomenclature in medicine is not seldom a source of much misunderstanding. The French, keen observers, have often been responsible for labels descriptive of morbid anatomical appearance alone. Grancher's *splénopneumonie*, now better known as epituberculosis, offers a good example. When, however, Empis, in 1865, applied the term "*granulie*" to acute miliary tuberculosis, he clearly wanted to distinguish the condition from pulmonary tuberculosis. Although the tuberculous nature of the disease was soon recognized, the name *granulie* has persisted in France to the present day. In more recent years evidence from various sources has accumulated which indicates that the appearance of *granulie* did not necessarily imply rapid death, and in 1924 the "rumblings" were crystallized in a paper by Burnand and Sayé,¹ who attempted to differentiate a new clinical entity—*granulie froide*. Impressed by the fibrotic disseminated tubercles seen post mortem in the lungs of a boy of 12, who had ailed for four years, and shown fine granules in the chest skiagram when he came under observation fourteen months before his death, they collected over twenty cases, in both children and adults. In these, similar symmetrical fine shadows were revealed radiologically; the patients presented only mild constitutional symptoms and very slight or no fever—hence "*froide*"; and the clinical course lasted one, two, and even up to ten years. Finally, they suggested that such patients could probably completely recover. The term "*granulie froide*" was taken up with enthusiasm, but a recent discussion in Paris² has shown that considerable confusion still exists on the subject.

No one will deny that a clinical syndrome which in the living patient is primarily based on a chest skiagram must be accurately defined in that respect. For while the presence of tubercles in other organs is undoubted, they are not there so easily detected except in the later stages. Thus Duken,³ Hellgren,⁴ and Miller⁵ have published x-ray photographs of cases showing calcified tubercles in the spleen, liver, and mesenteric glands. Ameuille, Burnand, Debré and Lelong, and Besançon emphasized the care needed to exclude other conditions which may give an appearance not unlike *granulie*: pneumoconiosis, carcinomatosis, dissemination following haemoptysis, diffuse fibrosis, congestion, and even the sequel of lipiodol injection. Little difficulty should be experienced in the differential diagnosis, especially if one remembers to look for fine

nodules of similar size, symmetrically disposed in the whole of both lungs.

Inadequate attention was, however, drawn to two other aspects of the syndrome. Bacteriological control by guinea-pig inoculation of the gastric lavage centrifugalized deposit is a method widely employed on the Continent in children, and now practised by Clausen in Copenhagen and Sayé in Barcelona, even in adults. And the development of a lesion in one or more organs at some stage of the illness is not infrequent. Léon Bernard, disregarding anatomic-pathological evidence, concluded that it was unnecessary to distinguish a special clinical form "based entirely on an x-ray picture"—a picture "representing merely a certain type of lesion met with in many clinical forms and associated with other lesions." He thought that it was merely "a transitory state, often initial, of tuberculosis, but was not a special form." Debré and Lelong admitted the existence of such a special chronic form in children, but they considered it to be merely a transitory stage of acute miliary tuberculosis, and described eight cases in which it led to death within three to nine months. Their findings may, however, be influenced by the fact that they deal with acute illness in a children's hospital, as contrasted with the chronic and contact material of a dispensary like Sayé's. This argument also applies to Lesné *et al.*, who stated that a large number of cases of *granulie froide* in young children are really subacute slow forms and always fatal, although they admitted the existence of a much more chronic form in older children.

Can the position be clarified? At the basis of the subject lies the conception of the common haematogenous origin of chronic pulmonary tuberculosis—a conception long held in France, extensively studied of late years in Germany (for example, by W. Page⁶), and recently introduced into American literature by Miller.⁷ The rarity of a bacillaemia in these conditions—concluded by Wilson in his critical survey⁸—need cause no surprise, as Miller points out, when it is remembered that even in acute miliary tuberculosis it can only be demonstrated in 40 per cent. of cases. Clinically evidence is accumulating in favour of a prolonged second stage of Ranke, for the tuberculous origin of conditions like pleurisy, erythema nodosum, phlyctenules, and anal fistula is steadily being recognized, and tuberculous foci in bones, kidneys, and skin, occurring successively or simultaneously, are not uncommon. It would indeed be remarkable if the lungs, filters of the lesser circulation, did not frequently become involved. The chronicity of these conditions and the varied clinical forms they assume—of which *granulie froide* is but one—must presumably be attributed to humoral factors about which our knowledge is still incomplete. The question is, however, not one of mere academic interest. In the presence of a "miliary" skiagram the practitioner should search for evidence of haematogenous spread elsewhere and seek the aid of modern methods of bacteriological

control. However mild or chronic, these cases are of serious prognosis owing to the probability of fresh crops of tubercles and to the likelihood of one of these episodes becoming acute. Indeed, Pagel⁶ has found that acute milary tuberculosis almost always arises from pulmonary tuberculosis which has had a haematogenous origin. Hence with regard to treatment, which is thus also prophylactic in nature, attention must be drawn to the satisfactory results obtained by Sayé with sanocrysin.⁶ It would appear, therefore, that the subject merits further study to clarify much that is yet obscure, but a plea must be made for the rejection of an expression which has already caused too much confusion. Even "chronic milary tuberculosis" represents only part of the truth, so that in view of the relative rarity of pure examples of the condition perhaps some justification may be found for a term which, though cumbersome, accurately describes the syndrome—"chronic disseminated haematogenous tuberculosis with pulmonary localization."

THE BIOLOGY OF SOCIAL LIFE

The basis of the scientific attitude is the recognition that all life is one and that progress in the knowledge of one part may be made by reasoned analogy from another. This was the faculty that made Francis Bacon unique in his time and enabled him to lay the foundations of modern inductive reasoning. In an attempt to find a solution for the urgent sociological problems of the day, the British Institute of Philosophy has arranged a course of lectures on the importance of a philosophy of life for mental health.* Professor W. Langdon Brown, in his opening lecture, on November 1st, on "The Biology of Social Life," diagnosed and interpreted some of the outstanding modern political problems in terms of biology. The results of his inquiry are most interesting. It seems obvious that, man being a social animal, he must be subject to the biological laws which govern life in general and gregarious animals in particular, yet few writers have examined him in the light of this truth.

Professor Langdon Brown's theme is that the most striking quality about the living cell, from which all life starts, is its insistent urge to assert itself as strongly as environment will admit. The whole story of many-celled organisms is one of mutual adjustment between the different tissues. At first a number of single cells herded together for mutual support and each did the same work. In the next stage different groups of cells did different work, the central nervous system co-ordinating and controlling their efforts. The development of the invertebrate was checked by the fact that the nervous system could not develop without choking the digestive tract, and two ways of escape were found.

One was the gregarious habit in which each individual is absorbed into the community, like the bee or the ant; the other was the development of a vertebral column. The mesozoic vertebrates went in for mere size, and their central nervous system soon proved itself too rudimentary to control their vast bulk. As before, a substitute was found in gregariousness—co-operation between smaller individuals. The course of successful evolution has all along been to increase, not the size of the individual, but the size of the unit. For the mammal in general and for man in particular this has been a much longer, more painful, and more dangerous path than for the insect, because his brain is capable of so many different reactions. The development of communal life restricts the freedom of the individual, and man has not found this easy. As the unit has been enlarged from the family to the tribe, the tribe to the small nation, and the small nation to the empire, the individuals within the unit have been clamorous for self-expression and the small units within the empire for self-determination. There are two tendencies in eternal conflict: the general demand for enlargement of the unit, and the species-making impulse which attempts to segregate a particular type. The former instinct leads towards international co-operation; the latter towards the fanatic nationalism of many European nations to-day.

For the moment the segregating, species-making impulse has the upper hand. One of the most disturbing features of the present political situation, as Professor Langdon Brown sees it, is that the nations which have forsaken the higher ideal for the lower seem perfectly content. They appear even to have gained a new hope, a new faith, and a new stability. The new level is more suited to their evolutionary development and they are more comfortable in it. Liberty is regarded as a curse, tyranny as the way of salvation. Nevertheless he holds, and we agree, that the position is fundamentally unsound. Although human beings in a community are the equivalent of cells in an organism, they have achieved self-consciousness and individuality. If the repressing force upon their originating and creating powers is strong enough, these powers will die and degeneration will follow. The solution, he thinks, can only be found by a method which gives adequate freedom to the individual life within a large co-ordinated unit. If our civilization is not to go back to the melting-pot, its members must remorselessly strip off the labels from outworn symbols, resolutely adopt reality principles, and realize the latent possibilities in human life. In the willing co-operation of free individuals for the common weal lies the only cure for the world's ills. Professor Langdon Brown, to his great credit, is optimist enough to believe that man may find this way to salvation. Of one thing he is sure. If this civilization falls it will be succeeded by a long period of chaos. In the course of centuries another dominant blend will inevitably arise and found a new civilization, but this thought holds little consolation either for us or for our children.

⁶ *Crisoterapia de la Tuberculosis*, Salvat Editores, Barcelona, 1933.

* Further lectures will be given at 5 p.m. on November 8th, 15th, and 22nd, by Dr. William Brown, Dr. Emanuel Miller, and Dr. Crichton-Miller, at University Hall, 14, Gordon Square, W.C. Applications for tickets should be made to the Director of Studies.

GENERAL MEDICAL COUNCIL ELECTIONS

Practitioners in England and Wales should have received last week the voting papers for the purpose of an election of a direct representative on the expiration of the present term of office of Mr. Bishop Harman, who is a candidate for re-election. Voting papers for the purpose of an election of a second direct representative on the expiration of the present term of office of Sir Henry Brackenbury, who has also been nominated for re-election, will be issued on November 13th. The last day for the return of voting papers in the first election was October 30th; for the second election it is November 20th. In order to enable practitioners readily to distinguish between the two sets of voting papers, white papers were issued for use in the first election, and the papers to be issued for use in the second will be coloured.

Under Section 9 of the Medical Act, 1886, when a vacancy occurs in the office of President of the General Medical Council, the Council "shall elect one of their number to be president for a term not exceeding five years, and not extending beyond the expiration of the term for which he has been made a member of the said Council." Sir Norman Walker, who succeeded Sir Donald Macalister in the presidential chair on November 24th, 1931, comes to the end of his period of office as direct representative for Scotland on January 1st, 1935. Sir Norman has now been duly nominated again for the constituency which he has represented without a break since January 1st, 1907, and his re-election may, we hope, be regarded as a foregone conclusion.

Our *Supplement* this week contains at page 231 the election address of Dr. Leonard Kidd, who for more than twenty-eight years has served as direct representative of the practitioners of Ireland upon the General Medical Council.

THE MOUSE AND INFLUENZA VIRUS

Two years ago the medical profession was still deploring the fact that a suitable animal was not available for the experimental study of influenza. Then last year came the announcement by Smith, Andrewes, and Laidlaw¹ that the ferret was susceptible to the virus of this disease and the convincing demonstration by them that, as many had suspected, the prime cause of influenza was a filterable virus. The use of the ferret also enabled these workers to show the close relationship, if not identity, of the virus of human influenza and the virus isolated by Shope from swine influenza. A relatively inexpensive animal was now available for influenza work; this was a great step forward. But there was one drawback to the use of the ferret. Its susceptibility to this virus was such that infection passed readily from animal to animal, so much so that stringent quarantine measures were necessary to make the results of experimental transmission of any value, and not every laboratory could do this. Andrewes, Laidlaw, and Smith² have just published a further paper on

their influenza work which is probably of even greater significance than their first. They find that, contrary to what they first thought, the mouse can be infected with the virus of influenza. If the virus is administered by nasal instillation to mice under light ether anaesthesia a proportion of the animals develop a bronchopneumonia which in the majority of instances has a fatal termination. Serial passage has been achieved by them in mice with ferret strains of both swine and human influenza virus, and filtration and cultural experiments have shown clearly that the disease in mice was due to a filter-passer. Further, these viruses have been shown to produce typical influenza in the ferret after having undergone several mouse passages, and neutralization tests have given final proof that the disease produced in mice was due to influenza virus. It is interesting to note that the serum used to neutralize the human strain of influenza virus is one that has been prepared in the horse; further details of this serum are to be published shortly, and will be eagerly awaited. Another important point emerges from this new work. It would appear that influenza in the mouse does not spread from animal to animal as it does in the ferret, thus doing away with all the elaborate precautions which have to be taken when working with the latter animal. This is of the greatest significance; for, with such an easily handled and inexpensive animal as the mouse available for work on influenza, and with elaborate precautions against spontaneous spread no longer necessary, this line of research comes within the scope of most laboratories. Transmission to the mouse direct from man has yet to be achieved, but there seem to be no sound reasons for doubting the possibility of this. Should this prove to be so one can hopefully predict a rapid advance in our knowledge of influenza in the near future.

NEWCASTLE SCHOOL OF MEDICINE

We published a short account of the history of the Newcastle-upon-Tyne School of Medicine thirty-seven years ago,¹ and we now welcome the addition² made to the story by Professor G. Grey Turner and Dr. W. D. Arnison. Both are well qualified to continue the tale, for both are distinguished alumni of the school, and the book appears appropriately on the occasion of the centenary of the school's foundation. The history is wonderful, and is a remarkable example of North Country grit and perseverance in the face of every obstacle. The school is the outcome of a desire on the part of a small band of local general practitioners to provide better teaching in a rapidly developing locality which was remote both from London and from Edinburgh. It began in the humblest manner, and at first the teachers themselves paid for the privilege of lecturing. The school had its troubles in the early days, but it was always strong in the existence of the general hospital or infirmary, where there was a wealth of clinical material and a fairly constant supply of men able and willing to teach. The energy of the teachers and the background of the infirmary soon gained

² Andrewes, C. H., Laidlaw, P. P., and Smith, W.: *Ibid.*, 1934, ii, 559.

¹ *British Medical Journal*, 1897, i, 213.

² *The Newcastle-upon-Tyne School of Medicine, 1834-1934*, by G. Grey Turner, assisted by W. D. Arnison. Newcastle-on-Tyne: Andrew Reid and Co., Ltd. 1934. (10s. net.)

recognition for the school by the great licensing bodies of the time, the Society of Apothecaries, the Royal College of Surgeons, and later the University of London. The school itself became affiliated to the University of Durham, although the teaching was carried out at Newcastle-upon-Tyne, and in due course, as the Faculty of Medicine, became an integral part of the university. Professor Grey Turner and Dr. Arnison continue the story, and show in admirable language and with a wealth of excellent illustrations the position of the school at the end of one hundred years—well equipped in every department and with a first-rate reputation. They lighten the dry facts and statistics with sketches of a student life which has now passed away, though it is within their own personal experience. They deal—perhaps too kindly—with the foibles of the “characters,” Hare Philipson, Murphy, McBean, and many others who seem to have been indigenous. Of them we should like to have had some of the stories told or invented by their colleagues and the students. Their kind is non-existent now, and can never be reproduced. On the whole a most satisfactory book and well worth reading.

ENDOMETRIAL HYPERPLASIA

Severe and irregular uterine haemorrhage is a symptom the gynaecologist often encounters, and of recent years attention has been focused on the condition known as endometrial hyperplasia. Burch, Phelps, and Wolfe¹ have written a general review of the literature devoted to this condition and included observations from their own experience, and from this paper the following points are taken. The French knew of a polypoid condition of the endometrium as early as 1846. Seven years later Brennecke noted the absence of corpora lutea in the ovaries of patients suffering from this type of haemorrhage, and suggested that an ovarian disorder was the cause of the endometrial changes. In 1900 Cullen introduced the term “endometrial hyperplasia,” but it was not until after the classical paper of Hirschmann and Adler, describing the normal cyclical changes in the endometrium, appeared in 1908 that a clear conception of abnormal histological appearances in the uterine mucosa could be obtained. The view of Schroeder that the uterine changes before ovulation were caused by a hormone elaborated in the follicle and those after ovulation by one arising in the corpus luteum is widely accepted. In endometrial hyperplasia the corpus luteum is absent, so that the normal changes in the endometrium which immediately precede menstruation fail to occur. The thickness of the endometrium may be excessive or not greatly above the normal, and indeed in many cases the diagnosis is not made without difficulty. “In still other specimens the bleeding originates in an endometrium corresponding in time relations and histology to the type seen in the interval phase . . . yet there is an absence of corpora lutea as evidenced by the absence of progestational changes.” It is therefore clear that the histologist is often dependent on an exact gynaecological history for his diagnosis. There is usually an absolute increase in the number of cells and glands, which sometimes present bizarre forms. Small cysts are frequently

observed in the endometrium, as are patches of oedema and small areas of necrosis. The cause of the bleeding is not clear, and the areas of necrosis may be the cause or the result of the haemorrhage. The persistence of the haemorrhage is due to the fact that two or three months may elapse before desquamation of the endometrium occurs. Indeed, desquamation to the basal layer may never take place. It is natural that attempts should be made to implicate the pituitary gland. The ovaries themselves are frequently the seat of an old inflammation and contain cysts. In many cases only one functioning ovary is present. Wilfred Shaw believes “that the polypoid endometrium reacts upon the ovaries to produce an inhibition of follicle ripening or of ovulation or of full formation of the corpus luteum: in turn the ovaries respond by producing continuously a toxin, identical in type with that causing the disintegration of the premenstrual endometrium in normal menstruation. In consequence disintegration of the superficial layers of the polypoid endometrium occurs.” The abundance of observations and the variety of views make it manifest that as yet little is known concerning the cause of endometrial hyperplasia. It may occur at any time in life, but is decidedly more common at or near the menopause. There is no evidence that it may develop into cancer, and its only danger is that consequent on haemorrhage. The condition is frequently associated with fibromyomata of the uterus. In young women repeated curettage may be followed by normal menstruation and pregnancy, and indeed the condition may clear up of its own accord or after various forms of therapy. Some authors have obtained good results from the exhibition of hormones, while others have had success with thyroid medication. At the menopause either radium treatment or hysterectomy is indicated, though the authors propose to try an old remedy of packing the uterus with gauze soaked in pure formalin. Endometrial hyperplasia is therefore to be regarded as one of the causes of severe and irregular bleeding which probably arises as the result of hormonal disharmony. Histologically it is characterized by hyperplasia of the endometrium, which does not undergo the normal progestational changes initiated by the hormone elaborated in the corpus luteum. The difficulty in the diagnosis of endometrial hyperplasia is illustrated by the fact that Taylor, in a review of the microscopical material of the Roosevelt Hospital, concluded that out of 216 cases diagnosed as such only eighty-eight deserved to remain in that category. Such a conclusion surely means that from the therapeutic point of view endometrial hyperplasia is at present of greater academic than practical interest.

THE FIGHT AGAINST DISEASE

The fourth quarterly issue this year of *The Fight Against Disease*, issued by the Research Defence Society, opens with an article by Sir Leonard Rogers on the reduction in the sufferings and deaths of children from diphtheria due to the use of anti-diphtheritic serum treatment during the last forty years. After illustrating by statistical tables the fall in the death rates since the introduction of antitoxin treatment, and stressing the importance of realizing its comparative failure when

started after the fourth day, Sir Leonard puts forward an approximate and conservative estimate of the life-saving value of diphtheria serum, based on the data published by Dr. Graham Forbes. He shows that probably 80,000 children have been saved in each year from death due to slow suffocation, or approximately 1,680,000 individuals in only twenty-one years out of nearly forty during which the serum has been available. He then deals with the arguments often advanced by the opponents of antitoxin treatment, especially with the long-exploded but still exploited total mortality myth. Another article discusses medical research from a layman's point of view, and there is a note on anti-vivisection advertisements in sub-post offices. A letter is published from a correspondent who was formerly an enthusiastic anti-vivisectionist, revoking his previous views, but holding that experiments might be more frequently performed on human beings than is at present the case.

HALL INSTITUTE OF RESEARCH, MELBOURNE

The fifteenth annual report of the Walter and Eliza Hall Institute of Research, Melbourne, opens with an appeal for additional support amounting to £1,000 annually, failing which measures of retrenchment implying reduced usefulness will become inevitable. It is hoped that an investigation of virus diseases, particularly of those affecting the nervous system, will shortly be started in close co-operation with the Commonwealth Serum Laboratories, supported by the Rockefeller Foundation. The investigation of Australian snake venoms continues to occupy a prominent place in the report, information now being available about the mortality of the various species and the decrease in their yield of venom in captivity. A study of the bacterial flora of their mouths showed that, whereas direct smears from the mouths of newly caught snakes contained few or no organisms, after a month or two in captivity the smears are crowded with organisms, including coliform bacilli, *B. proteus*, other bacilli which do not ferment lactose, staphylococci, and some anaerobes. Freshly collected venom contains but few organisms, and drying kills off many of the lactose non-fermenters. These findings are important from the point of view of immunizing horses, it being necessary to filter or otherwise sterilize venoms before using them for injections, or to devise better methods of collecting the venom. Neutralization experiments *in vitro* on the protective power of pooled normal adult serum against the virus of poliomyelitis indicated that it had only about one-third of the power of convalescent serum. Experiments on the sterilization of catgut drew attention to the importance of not relying upon an alcoholic solution of mercury biniiodide for this purpose, and led to the recommendation of the method of impregnation with iodine. A review of the accumulated evidence regarding lead poisoning and nephritis in Queensland emphasized the primary factor of chronic poisoning in childhood. The weathering of lead paint on the outside of houses and veranda railings exposes young children to a definite lead hazard, while some poisoning may result from spraying fruit and vegetables with lead arsenate. There is no indication that hereditary influences, scarlet fever, congenital syphilis, or other infections play any important part in causing

the increased mortality from chronic nephritis in Queensland, except in so far as they conduce to diminished resistance. The lines of future work are indicated, including the correlating of pathological changes in the kidneys of persons dying before middle age from chronic nephritis with evidence of the storage of lead in the body. Further legislation against the use of lead paint is also necessary, particularly in respect of house painting, the supply of articles for the use of children, and fruit spraying.

CHRISTINE MURRELL FELLOWSHIP

The October issue of the *Medical Women's Federation News Letter* makes further reference to the project for founding a post-graduate fellowship in memory of the late Dr. Christine Murrell. The members present at the annual general meeting in Sheffield felt that the best way in which they could honour their former president and treasurer was by the provision of means whereby the living might be served. Dr. Murrell's interest centred itself in general practice, and it was her conviction that in this sphere, with all its difficulties, lay a great opportunity for women of the right kind. She also took a keen interest in the question of medical education, and felt strongly the need for all doctors to keep themselves abreast of modern methods and teaching. It was agreed that a fitting memorial to one who had so much at heart the welfare of women in general practice would be the creation of a fund to be used to enable young women general practitioners to benefit by a course of post-graduate study. Many of our readers, men as well as women, would wish to take some part in thus commemorating Christine Murrell, whose work for the profession as a whole was recognized by repeated election to the Council of the British Medical Association and (a few months before her death) by election to the General Medical Council as direct representative for England and Wales. Donations may be sent to the treasurer of the Medical Women's Federation, 9, Clifford Street, Bond Street, W.1.

Sir Humphry Rolleston will give the FitzPatrick Lectures before the Royal College of Physicians of London on Tuesday and Thursday, November 6th and 8th, at 5 p.m. The title is "History of the Endocrine Organs."

On Wednesday next, November 7th, at 5 p.m., Professor A. Castiglioni will read a paper before the Section of the History of Medicine of the Royal Society of Medicine. His subject is "Morgagni and the School of Anatomy of Padua," which should prove as attractive to anatomists and surgeons as to medical historians, and the president of the Section, Sir StClair Thomson, asks us to say that visitors will be welcome.

The 1934 Nobel prize for medicine and physiology has been awarded jointly to Professor George F. Minot and Dr. William T. Murphy of Boston, Mass., and Professor George H. Whipple of Rochester, N.Y., for their researches into liver therapy in connexion with pernicious anaemia.

HARVEY MEMORIAL AT HEMPSTEAD

THE UNFINISHED TOWER

A further appeal is being launched this week for funds to complete the rebuilding of the tower of Hempstead Church, Essex, as a memorial to William Harvey, whose remains are deposited there. This parish church, seven miles from Saffron Walden and some fifty miles from London, is a fourteenth century building of much interest; it was closely linked with the Harveys, and contains memorials to other members of the family who achieved distinction in varied walks of life.

On January 28th, 1882, two hundred and twenty-five years after William Harvey's death, the massive tower, with its clock and fine peal of bells collapsed towards the south-west, and the stones lay in dismal heaps in the churchyard until eighteen months ago. The smallness and the comparative isolation of the parish of Hempstead were such that it was not possible to collect enough funds to make good the damage; all that could be done, in addition to some urgent temporary repairs, was to gather and stack the stones and flints, in the hope of some day rebuilding the tower. The Harvey vault, with lapse of time, also fell into disrepair, and in 1883 the Royal College of Physicians of London removed the leaden shell containing the body of the immortal William Harvey and placed it reverently in a marble sarcophagus in the Harvey Chapel of the church, where it now rests.

During the last few years a committee, comprising representatives of the medical profession, of Caius College, Cambridge, and Merton College, Oxford, of St. Bartholomew's Hospital, and of the parishioners of Hempstead, has striven to raise funds to re-erect the tower as a visible memorial to Harvey, and it has obtained altogether about £3,000. This sum was not enough to restore the tower to its full height, but the committee decided to make a start, in the hope that further money would be forthcoming to rebuild the ringing-room and the belfry. On July 7th, 1933, Lord Dawson of Penn, President of the Royal College of Physicians, laid the foundation stone of the new tower at a ceremony in which representative members of the profession took part.¹

We reproduce on this page a drawing by the architect, Sir Charles Nicholson, whose design for restoring the tower is agreed on all hands to harmonize perfectly with the ancient church. The arrows and black line show the point at which the work of reconstruction has stopped for the time being. The part below the line has already been completed, largely with old stone and flints from the fallen tower. A further appeal for the sum of £2,000 is now made to finish the work. The members of the Harveian Society of London, to mark their centenary in 1931, instituted a special fund for reconditioning and

re-hanging the old bells when the tower is built to the top, and this fund is held in readiness to round off the pious task of associating the name of "the great exponent of the experimental method in biology and the founder of scientific medicine" with his resting place in a little English village.

Donations are invited from members of the medical profession and others. They should be made payable to the Harvey Memorial Fund, and sent to Dr. G. de Bec Turtle, Royal College of Physicians, Pall Mall East, London, S.W.1.

The Chairman of the Harvey Memorial Committee is Sir John Rose Bradford, the vice-chairman is Lord Stanmore, the treasurers are Dr. Arnold Stott and Mr. A. W. Ruggles-Brise, and the honorary secretary is Dr. de Bec Turtle. Other members of the committee include the Bishops of Chelmsford, Colchester, and Barking, Sir Thomas Barlow, Sir Humphry Rolleston, Sir D'Arcy Power, Sir Archibald Garrod, Sir Farquhar Buzzard, Sir Charles Sherrington, Sir William Hale-White, Dr. Arnold Chaplin, Dr. Herbert Spencer, the Master of Caius, the Warden of Merton, the Master of the Apothecaries' Society, the Vicar and churchwardens of Hempstead, and the Editors of the *Lancet* and the *British Medical Journal*.

It is the earnest wish of the committee that the response to this appeal should be not only adequate in amount, but also thoroughly representative of the profession of medicine as a whole. The members of our profession are singularly qualified to estimate, at their real worth, the greatness and far-reaching character of Harvey's discovery, and to apprehend the truth and value of Harvey's exhortation to the Fellows of the College of Physicians, "to search out and study the secrets of Nature by way of experiment." It is to be hoped that the appeal will reach laymen

as well, for the name and fame of William Harvey are national possessions. His discovery of the circulation of the blood "remains to this day the greatest discovery of physiology, and its whole honour belongs to Harvey."

The first meeting of the new session of the Hunterian Society was held on October 15th, when Dr. W. H. F. Oxley delivered his presidential address, on "The Opportunities of General Practice." At the meeting of the society on November 19th, at the Cutlers' Hall, Warwick Lane, E.C., a discussion on "That the Lay Cult of Health has become Injurious" will be opened by Sir Ernest Graham-Little. The meeting on December 17th will be given up to a discussion on the diagnosis, prognosis, and treatment of coronary disease. The Hunterian Lecture, on "Rehabilitation Surgery," will be delivered by Dr. H. H. Kessler of Newark, New Jersey, on January 14th, 1935, and Professor John Eyre will give the Hunterian Oration on "Undulant Fever: A Retrospect," on February 25th. The annual dinner of the society will be held at the May Fair Hotel on February 14th, and the annual general meeting at Simpson's Restaurant on April 8th.

MEDICAL USES OF RADIUM

MEDICAL RESEARCH COUNCIL'S REPORT

The Medical Research Council has issued this week the twelfth of its series of reports upon the radium treatment of cancer and of some non-malignant conditions, summarizing the reports from the research centres for 1933.¹ In addition to describing work done during the past year, it supplies statistical data relating to the after-histories of patients treated in previous years, and contains a section dealing with some purely experimental inquiries into the action of radium. There has been a marked increase in the use of radium without any surgical operation, other than that termed "the surgery of access." Collecting the data contributed by the research centres for the years 1930 to 1933 inclusive, it is shown that a total of 7,955 patients suffering from malignant disease have been treated. Of these, 2,275 were treated by surgery alone (29 per cent.), and 3,415 by radium alone (43 per cent.). In 1933, out of 2,434 patients, 554 were treated by surgery alone (22.8 per cent.), whereas 1,240 were treated by radium alone (50.9 per cent.).

CANCER OF THE BREAST

Surgery, however, still maintains its prominence in the field of mammary cancer, owing to its success in early cases. Yet, since invasion of the axilla reduces markedly the prospects of a satisfactory outcome, it is stated in the report that there is therefore a definite need of radiological methods being explored to the utmost in dealing with extensions to this region. Interstitial radium therapy has been much employed in this part of the body, but it is not a favourable site for this procedure, there being so many important nerves and blood vessels in the vicinity which may easily be damaged and are difficult to restore to healthy functioning. It is suggested that *x* rays may constitute a more suitable agent. In the research centres surgery and radiology are being employed to an almost equal extent. Some of the chief advances in radium therapy of breast conditions have been made in this country.

Radium has been applied interstitially at Aberdeen and at St. Bartholomew's Hospital, both the primary growth and its probable extensions being dealt with simultaneously. After six to eight weeks the primary growth has been removed for investigation. In the last two years at Aberdeen it has been shown that under certain definite conditions of irradiation there are found comparatively few actively growing malignant portions. Results obtained at St. Bartholomew's Hospital indicate that the five-year survival rate is approximately the same for the two branches of treatment, being in each case about 40 per cent. It has now been decided there to combine interstitial radiation with surgery, the breast and glands being excised after radiation, and to compare the five-year survival rate with those of operation and radium respectively. In addition, an intensive histological study will be made of the breast and glands after removal, in order to find out: (1) the histological effects of radium on carcinoma tissue; (2) whether the treatment has destroyed all the tumour cells or left some areas untouched; (3) whether carcinomatous glands are effectively treated by radium; (4) the optimum time for excision of the breast after radiation.

At the Marie Curie Hospital in London a change in procedure is being made. In cases not suitable for radical operation some primary tumours and most of the recurrent growths will be treated by radium alone. Other primary growths will have interstitial radium for the primary focus, and *x* rays for the glandular extensions. Recurrences in the supraclavicular glands will be treated by deep *x* rays. Selected cases of primary cancer will be treated by deep *x* rays alone. Since cancer of the breast belongs to the group of the generally less sensitive types of this disease, the methods employed will be according to the principles of therapy, with special reference to the view of cell maturation elaborated by Coutard.

¹ Medical Uses of Radium. Summary of Reports from Research Centres for 1933. Medical Research Council, Special Report Series No. 197. H.M. Stationery Office, 1934. (8d. net.)

CANCER OF THE CERVIX

At Aberdeen thirty-seven cases of cervical carcinoma were treated during the year, the Heymann technique being practised when possible, or modified as the local occasion demanded: No case of vesico-vaginal or recto-vaginal fistula is known to have occurred. The Marie Curie Hospital reports a steady improvement in the ratio of early cases. Treatment has been by intervascular radium alone. Histological grading has been studied intensively, and a separate report on this is to be published. No evidence was forthcoming that the adenocarcinomata were insensitive to radiation. Complications have been of rare recurrence, probably on account of slight improvements in the technique. There is still much doubt about the pathogenesis of these reactions. Obliterative endarteritis seems to begin the lesion, and the rectal ulceration is suggestive of a broken-down infarct. The sudden development of massive infiltration, with or without ulceration, which often subsides as suddenly as it appears, is difficult to explain. Radium reaction is less frequent now than formerly. The Scottish associations of the Medical Women's Federation complain, on the contrary, that patients delaying until the disease is very far advanced are still all too common.

CANCER OF THE BUCCAL CAVITY

At most responsible radium clinics in the country there has been comparatively little difficulty in dealing with primary lingual growths by radium, the treatment being either interstitial or by means of larger units (1 gram and upwards) applied externally. As regards the glands associated with buccal cancer, there seems at present to be about an even balance of opinion and practice between surgical removal and irradiation, either interstitially or externally by radium, or by *x* rays. From Birmingham comes the warning that radium therapy is being demanded by many advanced cases still, and that statistics must be considered to lie under this handicap. The radio-resistant nature of tumours arising in leucoplakic patches has been particularly noted there during 1933, and in three such cases it was found necessary to excise the growth by diathermy after irradiation had failed. A slight improvement in oesophageal cases has followed the distribution of large doses of radon seeds (eight instead of four of 3 mc. each) throughout the length of the growth, and not only in the upper part as previously. The opinion at Birmingham with regard to malignant glands is that the only really valuable treatment is a block dissection, with complete removal of the sterno-mastoid. A new technique has been designed for growths in the tonsil or side of the tongue extending over or round the ramus of the jaw. To avoid trismus resulting from resection of the ramus and needling of the growth, a separate incision is made over the temporomandibular joint, and the capsule and ligaments are cut. The effects have been remarkably good, especially in the case of large growths extending from the tonsil into the pterygoid and mandibular muscles.

OTHER RESEARCH

At Aberdeen an investigation into the radiation treatment of adenocarcinoma of the ampulla of the rectum is being conducted. Eight patients, of whom five were technically inoperable, were treated by unscreened radon. In two the growth completely disappeared; three are still alive, with considerable palliation of the symptoms and reduction of the growth; and three died, but in these cases evidence of destruction of the growth in part was demonstrated at the necropsy.

While many cases reported from the centres show the unresponsive character of these growths to radium, others indicate an extraordinary good reaction to properly directed radiotherapy. There remains work to be done in correlating radio-sensitiveness with histological character.

The Royal Free Hospital has obtained good results in cases of functional menorrhagia of middle and later life, menorrhagia accompanied by physical signs, and the menorrhagia of puberty. There were treated 134 cases of the first of these, fourteen of the second, and six of the third.

At the Strangeways Research Laboratory has been investigated the irradiation of chick tissue in the presence

of blood circulation. It was found that degeneration was most evident in areas of active cell division and absent from non-mitotic areas. This has been shown to be a direct effect, which is less apparent after the third day of incubation. A stickiness seems to develop in the circulating erythroblasts, although chemical constituents necessary for clotting are not yet present in the blood. The blood vessels of the area pellucida are more easily damaged than those of the area opaca. At the Middlesex Hospital work in connexion with the histological classification of squamous tumours of the mouth region has been continued, with a view to determining if there is any relation between the histological appearance of a growth and its subsequent clinical behaviour, especially with regard to the response to irradiation. Among other conclusions it is mentioned that liability to metastasis may depend as much on the anatomical site of the growth as on its histological character, a fact, it is remarked, which has been too little considered in assessing the value of histological gradings.

BIRMINGHAM HOSPITALS CENTRE

INAUGURATION BY THE PRINCE OF WALES

The foundation stone of the Birmingham Hospitals Centre at Edgbaston was laid by the Prince of Wales on October 23rd. This ambitious and promising scheme, for the co-ordination of hospital services in the capital of the Midlands, is being carried out on a site of 150 acres (provided by the generosity of Messrs. Cadbury Brothers, Ltd.) near to the University, with whose medical school the centre will be in close connexion. The scheme is expected to cost ultimately one and a quarter million pounds, but only the first instalment of the total enterprise, costing about half that amount, is at present beginning construction. This first instalment, which will be completed in three years' time, provides 500 beds, and the entire scheme is designed to provide 750 beds, together with a separate wing for one hundred paying patients, and the housing of all the appropriate services in a self-contained domain. One feature of the Hospitals Centre will be provision for the treatment of rheumatic diseases by a variety of balneological methods, which will virtually bring the resources of a modern spa to the threshold of Birmingham.

The stone-laying ceremony took place at the spot where the skeleton of the administration block is already rising. The Lord Mayor (Mr. H. E. Goodby) welcomed the royal visitor to the city, and Sir Charles Grant Robertson, chief of the executive board of the Hospitals Centre, as well as Vice-Chancellor and Principal of the University (and formerly, as the Prince remarked in his speech, his own tutor in history at Magdalen College), outlined the objects of the centre. In laying the stone the Prince acclaimed the enterprise as one worthy of the progressive spirit of Birmingham, a pioneer scheme, unlike anything else at the moment being planned or carried out in Great Britain. After remarking on the urgent need for further hospital accommodation in a great and growing city like Birmingham, he said that those concerned had also realized how essential was a working partnership between the hospitals and the medical faculty of the university.

"It is up to the citizens of Birmingham," said the Prince in conclusion, "to see this scheme through. It is a voluntary one, and it is financed without any grants from public authorities, except in so far as the city of Birmingham has contributed to the construction of the necessary roads over the site. When we think of the economic crisis through which we have passed since the original appeal was launched in 1930 the response has indeed been remarkable, but, needless to say, more money is still required. In view of the need for further hospital accommodation and facilities for medical research and training, I would like to think that it will be readily forthcoming, and that the scheme will start three years from now free of debt."

Among those who were presented to His Royal Highness were Sir Gilbert Barling, Bt., F.R.C.S., late Pro-Chancellor of the University, and Dr. Stanley Barnes, dean of the faculty of medicine, who represented Lord Dawson

of Penn, President of the Royal College of Physicians of London; and the company included Sir Holburt Waring, President of the Royal College of Surgeons of England, Mr. Horace H. Rew, secretary of the Conjoint Examining Board in England, Dr. C. John Bridge, H.M. Senior Medical Inspector of Factories, Home Office, and Dr. C. M. Wilson, dean of the Medical School, St. Mary's Hospital, London.

NEW MEDICAL SCHOOL BUILDING

After laying the stone the Prince received gifts for the Hospitals Centre Fund. Among those who handed in gifts and had the honour of being presented was Dr. Clement Belcher, who was the first student to receive a medical degree at the inaugural ceremony of the University of Birmingham in 1901. It was announced that the fund had reached a total of more than £735,600, a record for a hospital appeal in Great Britain. His Royal Highness then walked to the site reserved for the new medical school building of Birmingham University, and, at the request of Mr. Walter Barrow, the Pro-Chancellor, cut the first sod. By this double ceremony he inaugurated a scheme which it is the proud belief of the citizens will make Birmingham in the near future one of the greatest hospital and medical school cities in the world. Before leaving Edgbaston the Prince visited the Students' Union, and recorded his name in the visitors' book. He afterwards visited occupational centres for the unemployed, and saw other aspects of social service work in Birmingham. He was also taken to the areas marked for slum clearance, and visited several of the dwellings. It is not before time that Birmingham tackles its housing problem. A recently published survey, by a group of citizens, states that in the seven central wards 19,000 houses, or 41.6 per cent., were found to be below a decent standard of habitation in point of disrepair, insanitariness, or overcrowding.

PATENT MEDICINES LEGISLATION

• STATEMENT BY ROYAL COLLEGE OF SURGEONS

The views of the Royal College of Surgeons of England having been asked for by the Standing Committee on Scientific Research of the Economic Advisory Council, the statement printed below was adopted by the Council after receiving the report of a committee, and it now appears in the annual report for 1934, copies of which may be obtained by Fellows and Members on application to the Secretary of the College, Lincoln's Inn Fields, W.C.1.

SALE OF PATENT MEDICINES AND APPLIANCES

The sale of secret remedies has in this country reached very large dimensions, and it is desirable in the interests of the public that it should be placed under some control. Among the objectionable features of the uncontrolled sale of these remedies we may mention the following: (1) The remedy may contain some drug which is injurious, such as acetanilide (headache powder). (2) More generally the remedy is purely fraudulent, containing no substance of therapeutic value. (3) The claims made for the remedy are always exaggerated and are, in general, purely fraudulent.

In many other countries secret remedies are either not permitted at all or are only allowed under the most stringent control. Thus in Germany a large group of preparations can only be sold under medical prescription, and may not be publicly advertised. In Austria the composition must be disclosed. In France they can only be sold under Government approval, whilst in Italy the prescription must be approved by the Government and accompany every package. In the United States the sale of medicinal preparations is regulated by the Food and Drugs Act, and every package must carry a label with the exact prescription. In Australia both the medicines themselves and all printed matter related to them are strictly supervised, and, in general, the prescription must appear upon the label.

In England it would appear that there is no effective control either of the composition of secret remedies or of the claims made for them, and, in fact, proprietary medicines are definitely excluded from the operation of the Food and Drugs Act. The only restrictions are those relating to scheduled poisons and to remedies for venereal disease. The situation cannot be better expressed than in the words of the Select Committee on Patent Medicines in 1914:

"For all practical purposes British law is powerless to prevent any person from procuring any drug, or making any mixture, whether potent or without any therapeutic activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any names he chooses, with payment of a small stamp duty, for any price he can persuade a credulous public to pay."

RECOMMENDATIONS OF SELECT COMMITTEE

The Select Committee recommended: (1) That the administration of the law governing the advertisement and sale of patent, secret, and proprietary medicines and appliances be co-ordinated and combined under the authority of one Department of State. (2) That this department be the Ministry of Health. (3) That there should be a Register of Manufacturers, Proprietors, and Importers of these remedies and appliances, and that every such person should require to obtain a certificate of registration. (4) That an exact and complete statement of the ingredients of every such remedy, and a full statement of the therapeutic claims made for any remedy or appliance, be furnished to the Department. Such information to be regarded as confidential.

The Committee made various recommendations for machinery to ensure the enforcement of their proposals. After careful discussion they definitely rejected the proposal that each article should bear a label describing its composition. The Committee referred to the enormous sums spent on advertising patent medicines, and to the opposition which may be expected from the Press to any interference or control.

PROPOSED LEGISLATION

Based on the proposals of the Select Committee, a Bill was introduced by Viscount Astor in 1920, but was withdrawn. In 1931 Mr. Somerville Hastings introduced a Bill supported by the Public Health Advisory Committee of the Labour Party, but this also was dropped. A Bill is at present being considered by the Parliamentary Committee on Food and Health, the object of which is to prohibit the advertisement and sale of medicines or appliances for the prevention, cure, or relief of certain diseases and conditions, the use of fictitious testimonials, and the offer of diagnosis and treatment by correspondence. The representatives of the patent medicine trade declined to support any Bill on the lines of the Select Committee, but it agreed not to oppose a measure such as has now been drafted.

In the opinion of the Council of the Royal College of Surgeons the problem can only be adequately dealt with on the lines laid down by the Select Committee of 1914 by bringing the sale of proprietary medicines and appliances under the control of the Ministry of Health. Such a control should ensure: (1) That the article in question is not injurious. (2) That the description of its therapeutic action is not fraudulent. (3) That the sale of the article in question and the methods of its advertisement are not against the public interest. (4) That no medicine or appliance is advertised as a cure for any of the following diseases and conditions:

Blindness.	Epilepsy.
Bright's disease.	Fits.
Cancer.	Locomotor ataxy.
Consumption.	Lupus.
Diabetes.	Paralysis.

This opinion was duly communicated to the Committee on Scientific Research of the Economic Advisory Council.

Nova et Vetera

THE EXECUTION OF CHILDREN

The Children and Young Persons Act, 1933, in Clause 50, says: "It shall be conclusively presumed that no child under the age of 8 years can be guilty of any offence." In Section 53 it is enacted that sentence of death shall not be pronounced on or recorded against a person under the age of 18 years. As a contrast to present-day views it is interesting to consider the attitude to juvenile crime which prevailed in olden times, when the ferocity of the law allowed such atrocities as the hanging of a child of 8 for arson and the burning alive of a girl of 13 for murder. An account of a few selected cases will be of interest to doctors and sociologists, and all who are concerned in the treatment of the juvenile criminal.

At Bury Assizes in 1748 William York, aged 10, was convicted before Lord Chief Justice Willes of the murder of a girl of 5, and was sentenced to death. The Lord Chief Justice was doubtful whether he ought to allow one so young to be hanged, so he postponed the execution till he had an opportunity of consulting the rest of the judges.

The following were the facts of the case. Both the children were parish children under the care of a parishioner, with whom they lived. On the day the murder happened the man of the house and his wife went out early and left the children in bed together. When they returned from work the girl was missing. The boy, when questioned, denied any knowledge of her whereabouts. A search was made, and it was found that a heap of dung near the house had been recently disturbed. This heap was searched, and buried in it was found the body of the girl, cut and mangled in a terrible manner. The boy was at once charged with the crime. He denied all knowledge of it. He was closely questioned, and then said he would tell the truth. He said the little girl was wont to "foul" her bed, and had done so that morning. (The bed was examined, and this was found to be untrue.) He took her out of bed and carried her to the dung heap, and with a large knife mangled her body and buried it in the heap.

The judges, having considered all these facts, agreed unanimously

"that supposing the boy to be guilty there was clear evidence of a mischievous discretion and he was certainly a proper subject for execution and ought to suffer, for it would be a very dangerous consequence to have it thought that a child might commit such a crime with impunity. There are many crimes of the most heinous nature, such as in the present case the murder of young children, poisoning parents or masters, burning houses, etc., which children are very capable of committing; and which they may in some circumstances be under strong temptations to commit; and therefore, though the taking away the life of a boy of 10 years old may savour of cruelty, yet as the example of this boy's punishment may be the means of deterring children from the like offences; and as the sparing of this boy, merely on account of his age, will probably have a quite contrary tendency, in justice to the public the law ought to take its course; unless there remaineth any doubt touching his guilt."

In this general principle all the judges concurred. Two or three, with some slight element of mercy, suggested another reprieve for the boy, in case there might be any element of doubt as to his guilt. This was granted, but as the Lord Chief Justice received no evidence to help the boy he ordered his execution. However, the Secretary of State later granted him a pardon upon condition that he would enter the Navy, and thus the horrible tragedy of the execution of this child was averted.

At Abingdon in 1629, John Dean, aged 8, was tried for burning two barns in Windsor, and as it appeared he had "malice, revenge, craft, and cunning," he was sentenced to death and actually hanged.

At Dorchester, in 1794, a girl, Elizabeth March, was convicted of the murder of her grandfather, and was executed; and in 1828 a boy, Giles East, aged 17, was convicted at the Kingston Assizes for carnally knowing

a girl of 9 years, and was hanged. There is also recorded at a much earlier date the case of a girl of 13 who was burnt alive for the murder of her mistress. There is a record of a case of a child under 7 years who was tried for murder. The jury found that when the crime was committed the child was under 7, and a pardon was therefore granted.

The method of hanging in these old days was much more cruel and brutal than that of to-day. The victim was placed in a cart under the gallows, the rope put round his neck, and the cart drawn away, or he mounted a ladder, which was afterwards withdrawn. In all cases death was prolonged, and due to slow strangulation. Sometimes the friends (for executions were in public until 1868) or a kindly executioner would hang on to the feet of the victim, and thus bring about death more quickly. It was about sixty years ago that the method of the long drop was adopted; this caused instant death by breaking the neck. Some very good specimens of fracture-dislocation of the cervical vertebrae by execution are to be seen in the museum of the Royal College of Surgeons in Lincoln's Inn Fields, London.

L. A. PARRY.

England and Wales

Welsh National Memorial

In the twenty-second annual report of the King Edward VII Welsh National Memorial Association (Prevention, Treatment, and Abolition of Tuberculosis), which covers the twelve months ended March 31st, 1934, are included the reports of the council of the Memorial Association, the principal medical officer, the directors of research and education, the research bacteriologist, medical superintendents of hospitals, and area tuberculosis officers. Five clinical studies are published relating respectively to epituberculosis, milk infection in children, miliary tuberculosis at the clinic, an analysis of cases admitted to the South Wales Sanatorium in 1933, and hydatid disease of the lung in a child. The report concludes with medical statistics (Memorandum 37 T revised) concerning the work of the dispensaries and hospitals and the immediate results of treatment. Successful progress was made during 1933 with the work of erecting the new hospital at Hayes Farm, Sully, which will contain 300 beds. The extension programme of the council envisages the provision of 500 new beds, and it is proposed to place the remaining 200 in a hospital near Swansea. Discussion is proceeding as regards a suitable site. At a conference held in Carnarvon last November various practical recommendations were approved for submission to the councils of certain northern counties in Wales where there is a high tuberculosis death rate. Two Welsh-speaking health visitors were also appointed for the Anglesey and Carnarvon and the Merioneth and Montgomery areas respectively; they began work last March. Dr. D. A. Powell, principal medical officer of the association, records decreases in the numbers of new cases and of contacts examined, the latter being due partly to shortage of staff. There was, however, a rise in the incidence of, and the death rate from, pulmonary tuberculosis in young adults. A statistical table shows that the age period 15-25, and particularly the lustrum 20-25, is by far the most susceptible for pulmonary tuberculosis, and the decade 5-15 for non-pulmonary. It has been suggested that we are reaping the aftermath of the war, persons belonging to the most hardly hit age, about 20, having been born during the war years. A more important factor is thought to be the industrial depression, with its repercussions on physique, nutrition, and morale, on the ebb and flow of the population, and, therefore, on the individual make-up of that population as regards age, sex, and vigour. Professor

Cummins, director of research, states that acid-fast bacilli other than the tubercle bacillus have been receiving continued study in view of their appearance in the sputum of patients who were certainly not tuberculous. Two strains have now been cultivated and are under detailed examination. Investigations on sensitivity problems promise useful results; one series has cast doubt on the value of the subcutaneous test in tuberculosis, a considerable number of positive reactions having been obtained in patients free from any of the signs or symptoms of tuberculosis, though probably infected to a greater or less extent in a degree consistent with health. Dr. R. Owen Morris, director of education, contends that emphasis should not be laid on the negative policy of avoiding disease, but rather on the positive virtue of keeping well. The laws of health should be more widely taught to the young, who alone have sense to profit therefrom, and have not yet contracted faulty habits of thought. As in previous reports of the association, a wide range of topics is covered in the various incorporated statements by medical officers of hospitals and dispensaries. Dr. R. J. Matthews of Mid-Glamorgan, for example, expresses the view that tuberculosis officers should devote themselves to treatment rather than to differential diagnosis, which could be left more economically to medical practitioners and hospitals. He also thinks that hospital dietaries could be made more palatable and less monotonous, with therapeutic benefit, while institutional regulations could be relaxed with similar advantage. Dr. R. M. Hiley of Pontypridd and Rhondda stresses the value of the dispensary as a unit in the tuberculosis scheme when associated with good domiciliary work. Others suggest that, while present-day patients are seeking medical advice earlier than used to be the case, the disease is more extensive when first detected, indicating that it is now of a more acute type. Reference is made to the importance of realizing that a definite history of pleurisy in adults means in a very large proportion of cases definite—not threatened—tuberculosis, with the disease in its most favourable form for treatment. Moreover, prolonged or frequently recurring respiratory attacks in young persons should be regarded with suspicion and the patients subjected to careful examination. The steady advance of pneumothorax as a valuable line of treatment is noted. In these and many other respects this annual report sheds light on the way in which the treatment and the prevention of tuberculosis are advancing side by side, the conclusions being reached by a survey of an adequately large number of patients by physicians of varying outlook and long experience.

Cerebro-spinal Fever in England and Wales

In a communication to the Office International d'Hygiène Publique, published in the September *Bulletin*, Dr. M. T. Morgan gives the following survey of the incidence of cerebro-spinal fever in England and Wales. The notifications, which in 1931 had amounted to 2,157 in a population of about forty millions and in 1932 were 2,136, fell to 1,695 in 1933. In the West Riding of Yorkshire, where the increase was greatest, the notifications in 1933 were not half the number of those in 1931. The general incidence of the disease, therefore, though still above the normal, shows a well-marked decline. Examination of the serological type of meningococci from 169 cases of cerebro-spinal fever during the period April 1st, 1933, to March 31st, 1934, showed that 112 (66 per cent.) belonged to Group I and fifty-seven (34 per cent.) to Group II, whereas during the war the epidemic of cerebro-spinal fever was caused by meningococci belonging to the two groups in about equal proportions. During the period 1931-4 the epidemic showed little tendency to

spread beyond the West Riding, although the disease showed some degree of abnormal frequency in the adjacent county of Derbyshire. The cases in which meningococci of Group II were isolated did not differ clinically from those due to Group I, though that may partly be due to the disease being principally found in infants. In 811 cases in which serum treatment had a fair chance of acting the fatality was 26.9 per cent., although in many of these cases it was not employed until late in the disease.

The Health of Holborn

The report of the medical officer of health for Holborn for 1933 contains many reminders of the late Dr. C. W. Hutt's wide outlook and his enthusiasms, as well as of his attention to detail. It is interesting to note, in view of some of his previous reports, that nuisances arising from litter on the public highway have been mitigated, following steps taken by the dust inspector to secure the use of properly covered ashbins in streets where the refuse is put out on to the footway. Efforts have also been made to prevent the turning over of the refuse by children. Routine inspections were made of 533 factories, 614 workshops, and 3,376 workplaces. It is remarked that workshops are automatically converted at a very small cost into factories by the installation of a small electric motor; the health conditions then may no longer be inspected by the staff of the borough council, except as regards sanitary accommodation. The more important industries carried on in these factories are printing, engineering, bookbinding, and metal work. There were 1,046 inspections of market streets containing stalls at which meat, fish, fruit, and vegetables are sold. This regular inspection helps to secure the sale by stallholders of sound food only, and also discourages casual and unsatisfactory hawkers who generally avoid streets that are under strict supervision. The large day population in the borough calls for many eating-houses ranging from the "cookshop," where cheap meals are provided, to the high-class restaurant. Inspection of the kitchens of such places has become a routine but important part of the work of the public health department. Generally, it is stated, the kitchens are found to be satisfactory and the food clean and wholesome. Now and then, however, some action is needed to ensure compliance with a reasonable standard of efficiency. The report refers to the urgent need of establishing definite standards for cream, cheese, and other foodstuffs; a small permanent committee or board of reference should be appointed with power to make recommendations or amendments. The great advances in the scientific investigation of foodstuffs have made new standards imperative. Such a body should be in a position to consider the new methods of examination which are constantly being evolved, and to prescribe the appropriate value to be attached to them in determining the purity, or otherwise, of articles of food.

Conference on Mental Welfare

A conference on mental welfare will be held in the Great Hall, British Medical Association House, Tavistock Square, W.C., and at the Royal Agricultural Hall, Islington, N., on Wednesday to Friday, November 21st to 23rd, inclusive. Arrangements have been made to hold this conference in the same week as the Public Health Congress, so that the Central Association for Mental Welfare may collaborate with the committee of that congress for one session, and also that the travelling expenses of delegates may be saved. An exhibition of the work of defectives who are being taught under the scheme organized by the Central Association for the Middlesex County Council in occupation and industrial centres, and in their own homes, will be on view in a room adjacent

to the conference hall at B.M.A. House. On the first morning there will be a joint session with the Public Health Congress at the Royal Agricultural Hall on boarding out from mental hospitals, when the chair will be taken by Mr. L. G. Brock, chairman of the Board of Control. The morning of the second day will be devoted to a discussion on modern tendencies and developments in work for mental defectives, with special reference to institution care, community care, and research. In the afternoon Mr. Brock will preside over a discussion of the voluntary provisions of the Mental Treatment Act. Friday morning is left free for delegates to be able to attend a session of the Public Health Congress on voluntary sterilization and the report of the Departmental Committee on Sterilization. Friday afternoon will be spent in a discussion of the work of the educational psychologist, and of some experiments in the training of the retarded child. Mr. Herwald Ramsbotham, Parliamentary Secretary to the Board of Education, will give an opening address. Tickets, at 10s. 6d., to include advance copies of the papers, will also admit to the Wednesday and Friday morning sessions of the Public Health Congress. They can be obtained from the secretary of the Central Association for Mental Welfare, 24, Buckingham Palace Road, S.W.1. A luncheon for delegates will be held at the Hotel Russell on Thursday, November 22nd, at 1.15 p.m., when Sir Hilton Young, Minister of Health, will speak. Luncheon tickets, price 6s., must be obtained beforehand from the offices of the Central Association.

Instrument Manufacturers at Dinner

The annual dinner of the Surgical Instrument Manufacturers' Association (Incorporated) was held at the Holborn Restaurant, London, on October 26th, with the new president, Mr. H. Guy Drew (Down Brothers, Ltd.), in the chair. Mr. W. H. Ogilvie, in proposing the health of the association, contrasted the progress of surgical instrument manufacture with that of the motor-car industry, the latter seeming to him to typify all that the former should not become. The consumers in the motor-car industry were becoming every year less skilled in technique and more desirous of appearance and speed. Cars were turned out by mass production, in which craftsmanship was sacrificed. On the other hand, the making of surgical instruments was still a craft, even though routine work had to be done to some extent. Its products were built to meet special needs, and the user and the manufacturer were continually in counsel. The making of surgical instruments demanded long training, hard work, the best materials, and the most scientific testing. The maker had to be an expert in wood, leather, metal, glass, something of a physicist, perhaps a chemist, certainly a mathematician, and also a fashion designer. In Mr. Ogilvie's view the fourth age of surgery was near. The first age was the primitive one, extending into the lifetime of some of those present, when, although it was true that bones were set, limbs amputated, and stone removed, the patient very often died, and the instruments used were not greatly different from those employed in Pompeii. The second age started with Lister and ended with the war. The third age was one of consideration and criticism, the collection of enough experience to be able to abandon bad methods and eliminate unnecessary steps, until technical skill had reached a stage when it seemed to some it could not go further. But in the new epoch, with finer contrivances, new opportunities for the surgeon would arise. Already there were available instruments which reduced considerably the time spent on major operations, or enabled stitches to be put with mechanical exactitude into hitherto inaccessible positions. He concluded with an expression

of his own personal gratitude to the surgical instrument maker. He had taken him on occasion some Heath Robinson-like drawings, and from them the instrument maker had contrived something exactly to his purpose—really his (the surgeon's) own instrument, though he was probably the only person who could recognize it as such. Mr. Drew, in response, spoke of the astonishing number of new patterns which, at the call of the profession, the instrument makers were required to produce. In view of this great fertility of invention it was important that the industry should be as free as possible from restrictions and the domination of outside interests. He mentioned that it was proposed to form an institute to look after the education of those entering the industry. In reply to the toast of "The Guests," proposed by Dr. A. N. Gardner, Dr. G. C. Anderson, Medical Secretary of the British Medical Association, also spoke of the service which the craft had rendered to the profession, and through them to the community. He mentioned that the hosts of that evening had co-operated with the British Medical Association and other bodies in furthering a Bill to prevent the indiscriminate advertising of surgical and other appliances. Although the proposed measure was not as far-reaching as had been hoped, yet the Bill, if it could be got through, would do much to redress a very present evil. Dr. Anderson also mentioned that the register of medical auxiliaries, with which the British Medical Association had had much to do, had taken a wider connotation, and he hoped that in course of time all who were occupied in any branch of work ancillary to the medical profession would be placed on a national register.

Duration of L.C.C. Specialists' Sessions

The London County Council as recently as June last decided that a session in relation to the employment of all consultants and specialists should be a period of approximately two and a half hours' duration. The Hospitals and Medical Services Committee, however, has decided that the request of an assistant physician for x-ray work at one of its hospitals that the length of his sessions should remain at two hours is one that should be granted, his remuneration remaining unaltered. In this particular case the duration of the session was two hours under the terms and conditions of service laid down by the late authority at the time of the specialist's appointment. He also, in order to economize time, owing to the necessity for "tuning up" the x-ray apparatus before it can be used on each occasion, works in double rather than single sessions, and it is stated that the work can be done in sittings of four hours each. The situation of the hospital requires a journey by car of about an hour each way from and to Harley Street, for which no travelling expenses are payable.

Reconstruction of a London Fever Hospital

The Hospitals and Medical Services Committee has submitted to the London County Council proposals for reconstructing and modernizing the North-Eastern Hospital for Infectious Diseases, South Tottenham. At present the hospital contains 661 beds, of which 509 are in temporary buildings. The new buildings will provide for 608 patients, making, with the 152 beds in existing permanent buildings, a total of 760, or just upon one hundred more than at present. The work is to be spread over three or four years, so as not to affect materially the patient accommodation at the hospital. The new buildings will comprise eight two-story general ward blocks, two two-story isolation blocks, and four single-story buildings, containing patients' receiving and discharge sections and other departments. Each of the general ward blocks will contain sixty-two beds, and on

each floor there will be twenty beds in open wards divided by dwarf glazed screens into bays of four beds each, also five one-bed and three two-bed isolation wards. A T-shaped plan has been adopted for the open wards, so that from a centrally placed combined ward kitchen and duty room most of the patients can be kept under observation. The planning of the new blocks will secure the maximum of sunshine, together with effective ventilation, as a folding type of casement window will be provided to enable practically open-air conditions to be secured without movement of beds. At the outer ends of the wards sun verandas will be provided. Each of the isolation blocks will contain fifty-six single-bed rooms, with a centrally planned entrance, duty room, and sanitary unit. An operations block is to be erected, containing on the ground floor an operating theatre, anaesthetizing room, sterilizing and preparation rooms, and an x-ray and light treatment unit with separate entrance; and on the upper floor a teaching section, with lecture room, demonstration room, library, and laboratory of three rooms. The estimated cost of the work is £209,443.

Scotland

Biology in Education

A Scottish national conference on "The Place of Biology in Education," organized by the British Social Hygiene Council, met in the City Chambers, Edinburgh, on October 19th. Sir Basil Blackett acted as chairman, and the Rt. Hon. Sir Godfrey Collins, Secretary of State for Scotland, opened the conference, which was attended by some 160 delegates representing Scottish Government departments, universities, local authorities, and educational institutes. Professor F. A. E. Crew, in a paper on "Biology Applied to Human Problems," said that a serious disability of the modern world was the sense of purposelessness which was encountered on all sides, and it was important to remove this from the minds of those to whom the future belonged. To numbers of young people the present seemed to be meaningless, with the result that they were apt to cultivate a harmful hedonism or to attack enemies created by their own ignorance and imagination. In the teachings of the biological sciences there might be discovered serenity, hope, and purpose, which could give enjoyment to the acts of living, and of all the adventures of to-day the greatest was to be found in the search for knowledge. Man had performed remarkable feats in the past by changing the characters of domesticated animals and cultivated plants to his own advantage, and by the same methods mankind might be refashioned if it only knew what it wanted, and wanted this sufficiently ardently. There was nothing in biology which denied that the universe would continue to be as creative in the centuries to come as it had been in the past, but development and differentiation must be controlled and directed by man. Mankind was able to destroy or control all living competitors for supremacy, but the continuance of mankind was not necessary for the advancement of life, and if man did not continue to advance, some other form of life would occupy his place. The future might see types of humanity and of social organization very different from those existing to-day. Professor James Ritchie (Aberdeen) said that attempts to make a school course in biology a kind of attenuated university course were sure to end in disaster. The teacher of biology at present required to have an honours degree in science, but this was a useless requirement for teaching biology in the schools. The honours year for a degree in science was a year of

specialized research, which could have very little bearing on the teaching of biology to school children. If a student had taken a particular science subject, he could be regarded as having the necessary qualifications for teaching that subject, and an extra year would be more profitably spent on an intensive study of common British animals and plants than on doing honours work. This study should not be of the structure and differentiation of animals and plants, but should be an investigation of their life-histories and environment. Sir Thomas Holland, Principal of Edinburgh University, who presided at the afternoon session, said with regard to the study of biology that there was at present the difficulty that students had to take this as an extra subject, and some means must be found of getting over this difficulty, as, for instance, by co-operation between the universities and the schools. He was not sure that it would not be a good plan to make biology a subject for entrance to a university course. Professor James Ritchie considered it was an astonishing sign of the times that, whereas at every stage of education biology was being accepted as a necessary ingredient, the General Assembly of the Church of Scotland should, in 1934, have abolished the only chair of natural history in the Church colleges, which had been occupied in succession by Professor Henry Drummond and Professor J. Y. Simpson. The suggestion that natural science could be adequately taught to divinity students by the professor of another divinity subject showed a strange ignorance of the progress of the study of life and of the equipment desirable in men who were to guide the people in the ways of religious and social advancement. Dr. J. B. Orr, Director of the Rowett Institute, Aberdeen, who summarized the day's discussions, said that they were moving on to a time of a higher material standard of life, but also to a time of a higher intellectual outlook. There was especial need in the direction of affairs of men who had a biological outlook, and all who set themselves to guide and direct the people should have a systematic training in biology. On his recommendation a resolution was adopted by the conference requesting educational and administrative authorities to do their utmost to secure greater prominence for general biology at all stages of education.

University of Edinburgh

At the half-yearly meeting of the General Council of the University of Edinburgh, held on October 26th, the Business Committee reported that the total enrolment of full-time students in the universities of Great Britain for the session 1932-3 had been 50,155, of whom 74.3 per cent. were men and 25.7 per cent. women. The medical faculties in the British universities had shown an increase of 807 students. Of the total students 35,813 were in England, 10,975 in Scotland, and 3,367 in Wales. This showed a considerable excess of university students in Scotland as compared with England in proportion to the total population. The total disbursements for Edinburgh University during 1933 had amounted to £293,764. Principal Sir Thomas Holland, in a survey of the university during the year, said that out of the total of 4,478 students in British universities from outside the British Isles Edinburgh had 505, while Oxford had 524 and Cambridge 538. It had been agreed at a universities congress in Edinburgh in 1931 that as a general principle students from over-seas should, as a rule, be discouraged from coming to British universities to take a first degree, but that they should be encouraged to come for special training or post-graduate instruction. In Edinburgh an adviser of over-seas students had been secured in the person of Mr. Gaudin, a former master at Merchiston, and Sir Thomas thought that the distant parent or

guardian had now no good cause for feeling alarmed about the life and comfort of the boy who came to Edinburgh University. Since the 350th anniversary celebration last year of the foundation of Edinburgh University, over 1,000 new members had joined the Graduates' Association. There had also been up to date an increase of 174 in the number of students in the faculties of medicine, science, law, divinity, and music, although there had been a fall in those joining the faculty of arts. A special feature in the university had been the progress made in the various forms of physical training instituted five years ago under the control of Colonel Campbell. Physical training for the ordinary student was of more importance than record breaking by recognized athletes. With regard to accommodation, the provision of hostels was increasing, and 527 students were now provided for in this way, or 14 per cent. of the total. The increase of modern transport facilities meant, however, that a larger number of students lived at home in the districts surrounding Edinburgh, or 47 per cent. of all the students. Of the remaining 39 per cent. there were many who would gladly enter hostels if accommodation were available.

Glasgow Graduation Ceremony

At a graduation ceremony held in Glasgow University on October 20th, Principal Sir Robert Rait conferred degrees on 116 students, including 104 students of medicine. In congratulating the graduands the Principal said that the progress of knowledge in their own time had added greatly to the burdens which fell upon the student of medicine. While students of other subjects could choose what they would study, there was a tendency for the layman to demand that his doctor should know everything about every disease. As fresh discoveries were made and new discussions arose, the universities and the General Medical Council would have to consider important questions about the length and nature of the medical curriculum. Students did not pass from an exacting training to an easy life, and they must not consider the layman unreasonable in his demand. The latter trusted them because of the long and glorious tradition of the medical profession. To every generation the profession had given a response by increasing its power to heal. The exercise of the will to heal included continuance of studies as opportunities might serve. It also included the duty of keeping fit, the display of unwearying patience and self-restraint, the power of inspiring hope, and the sacrifice of ease and comfort.

Life Statistics in Scotland

A supplement to the seventy-eighth annual report of the Registrar-General for Scotland, which was summarized in these columns on October 20th, 1934 (p. 736), contains a report on life tables by the Government Actuary. It is pointed out that no complete official life tables based on Scottish statistics have appeared since those contained in the nineteenth annual report of the Registrar-General for Scotland based on the census of 1871 and the deaths of that year. The population of Scotland at the 1931 census was 4,842,980; this was a decrease in the ten years since the previous census of nearly 40,000. This census population was smaller by some 12,000 than the calculated figure. It was found that the mortality of married men was much lighter than that of single men or widowers, and that the mortality of widowers was heavier than that of either of the other classes. There was less difference in the case of females. At every age, however, the rates of mortality of widows were appreciably heavier than those of single or married women. The mortality experience was investigated in Edinburgh and Glasgow, in the twenty-

four large boroughs excluding these two cities, in the northern counties where the population is sparse, in the central counties, which form the industrial area, and in the southern counties, which are predominantly rural. It was found that the mortality rates for Edinburgh were more favourable than those for the country generally at the lower ages in both sexes. The heaviest rates were found in Glasgow, where at every stage of life the mortality was less favourable than that of the country as a whole. As the population of the city of Glasgow was approximately one-fourth of the total population of Scotland it followed that this mortality experience affected materially the rates shown in the Scottish national tables. Density of population, accompanied presumably by a considerable element of unsatisfactory housing and environment appeared to be the factor to which excess of mortality over the average of the whole country was traceable, and incidentally created a comparatively high national average because the population to which these unfavourable conditions were applicable included 2,631,320 persons as against 2,211,660 living under more favourable conditions. It is apparent from comparative tables that between the censuses of 1921 and 1931 there was a substantial improvement in the vitality of the people of Scotland. The probability of a child, whether male or female, dying in the first year of life decreased by nearly 12 per cent. The decrease in the mortality rates was most marked at the younger adult ages, and at the age of 30 amounted to over 20 per cent. At the advanced ages, however, there was evidence of deterioration, and the death rates at ages over 80 were greater in 1931 than in 1921. The supplement to the report may be obtained from H.M. Stationery Office, 120, George Street, Edinburgh (price 1s. net).

Extension of Glasgow Mental Hospital

At the commencement of operations for the building of an extension to Hawkhead Mental Hospital, Glasgow, it was pointed out that the Glasgow Health Department now controlled 9,000 beds, which accommodated 50,000 patients annually. When the present scheme was completed there would be provision for a further 200 beds for mental cases, and a nurses' home with accommodation for 124 nurses. These buildings would cost about £120,000. A new experiment was being tried of eliminating the boiler house and heating the water for the institution by electricity, which, it was thought, would be cheaper than the coal fire.

The nineteenth annual report of St. Dunstan's for the year ended March 31st, 1934, is able to record successes which justify its appeal for more money. The institution still looks after about 2,000 men in one way or another, and nineteen new cases of war blindness were admitted during 1933, including five gas cases, the pernicious effects of which had been delayed for over fifteen years (see *British Medical Journal*, October 27th, 1934, p. 769). In addition to the 2,000 St. Dunstan's looks after about 5,000 of their dependants. More work has been found for blinded masseurs, telephone operators, and other commercial and business men, while home-workers and craftsmen are still assisted. More than a quarter of a million articles made by them were sold last year—about the same number as in 1932. The large convalescent and holiday home at Brighton is also a training centre, and the wide variety of occupations which are available now for skilled men, though blind, is illustrated well in the report. More than a hundred are qualified masseurs, either attached to hospitals or in private practice. Nearly 200 poultry farmers are at work, many having been trained in the St. Dunstan's model poultry farm at King's Langley. Between 200 and 300 are keen gardeners, and all who wish are taught during their general training to play some musical instrument. The institution has its own dance band and singers.

Reports of Societies

PROGNOSIS IN CORONARY OCCLUSION

At the meeting of the Section of Medicine of the Royal Society of Medicine on October 23rd a discussion took place on the ultimate prognosis of coronary occlusion.

Professor JOHN HAY of Liverpool, in opening, said that prognosis was the most difficult task in medicine. A statistical approach, of course, was available, but it was primarily actuarial in its usefulness. A long series of cases helped one to assess with some confidence the true prognostic value of the various factors. There were two essentials in arriving at an opinion as to the future of a patient suffering from coronary occlusion: (1) a clear conception of the actual happenings in the heart, the underlying pathology, the changes preceding and following the coronary block; (2) the history of the disease condition. The future efficiency depended upon the extent of the necrotic area, the relative proportion of muscle fibre involved, and the integrity of the remaining myocardium. Occlusion might come suddenly and without warning, or there might have been an increasing liability to anginal pain or cardiac failure of the congestive type. Coronary occlusion having taken place, the patient might die suddenly from shock, or death might occur within a few weeks from ruptured heart. Cardiac failure of the congestive type might develop—rapidly from the onset of the occlusion; later on, slowly from the general deterioration of the myocardium. Those who survived the shock did so with a gravely crippled heart, and, of course, with the factors still persisting which had predisposed to the original occlusion. On the other hand, the patient had had his lesson, he was probably under medical supervision, and was prepared to live within his limitations.

The chances of surviving the first attack were difficult to assess because many of the milder cases escaped diagnosis, and those in which death occurred suddenly at the onset were often not included in the published statistics. The initial mortality was heavy. Carey Coombs, in a total of 144 patients, reported forty-nine deaths in or very shortly after the initial attack; of the surviving patients, thirty-two died within twelve months. A number of figures, not greatly different, from other observers were quoted. Of the survivors it could be said only that sooner or later they would die a "cardiac death." They could be divided into two groups. The first consisted of those in whom the cardiac disability was shown by an increasing tendency to dyspnoea and a gradual drift towards failure of the congestive type. Pain was not the dominant feature with these patients. In this group could be included those whose cardiac reserve was still further hampered by auricular fibrillation, which might have originated in the attack of occlusion or have appeared later and become permanent. The outlook for the patients in this group was bad from the start. Their future was measured by months. The second group consisted of those who made a satisfactory recovery, and were able to lead reasonably useful lives, though rarely entirely free from some form of cardiac distress. They learned, however, to live within their limitations, and sometimes showed surprising longevity. They eventually succumbed to some kind of cardiac difficulty: of course, they were liable to die from intercurrent disease, but it was remarkable how relatively few died from other than a cardiac cause. The life of the members of this group might be measured by years instead of months. If the first critical stage could be weathered, their expectation was two to five or more years. A classic example was John Hunter, who had his first attack of coronary thrombosis twenty years before his death, when he was 45 years of age; three years later he had a second attack, and during the last few years of his life was liable to recurrent attacks of effort angina; yet his life continued at high pressure throughout. Amongst his own patients the speaker had had one who died last year at 70, fourteen years after his first attack; he was

liable to slight angina of effort. On careful scrutiny two facts stood out: (1) the frequency with which life was ended suddenly, presumably by a terminal thrombosis, and (2) the significance of a progressive tendency to dyspnoea and congestive failure. The age of onset might modify the prognosis. The younger were more apt to recover, and, having recovered, their expectation of life was a little longer. He could not satisfy himself that any reliable inference was to be drawn from blood-pressure findings after the attack was over. If anything, persons with lower blood pressure fared worse. Electrocardiograms were of far more value in the diagnosis of coronary occlusion than in its prognosis. In his own cases glycosuria of a mild type did not appear to add to the difficulty or diminish the expectation of life.

Dr. T. F. COTTON said that the occlusion syndrome was very easy to recognize. When the patient was seen during an acute illness the clinical features were characteristic. It was said that half the patients died rapidly during the acute illness. If that statement were accepted there must be included in the group patients who died from a recurrence of thrombosis. To forecast the course of recovery from the acute illness was difficult. A good deal of useful information could be obtained by observing and recording the notes on those patients who presented themselves with a history of angina before it was known that the angina was a sequel of coronary thrombosis. Of the last 200 anginal cases of which he had notes, seventy-three gave a history of past occlusion or had occlusion at the time he examined them. Of this number, thirty-three had angina after the occlusion. These anginal cases after occlusion seemed to suffer an increasing disability from angina of effort, or spasmodic angina, or recurring thrombosis. He had not seen one case of good functional recovery in this anginal group, and of the total number he knew that twenty patients were dead. Of the other forty cases of occlusion, but not angina, sixteen patients were noted as having made a recovery. Of the patients who recovered from the acute illness, therefore, a large number would have angina and die as a result; but patients who had coronary thrombosis and did not get angina might be expected to make a good functional recovery. Prognosis was distinctly more grave in the anginal group after occlusion.

Dr. B. T. PARSONS-SMITH remarked that the title of the discussion implied recovery from a catastrophe which until moderately recent times was regarded as invariably fatal. As a result of clinical observation on the part of many workers, a reasonably clear-cut conception of coronary thrombosis was nowadays recognized, and although the differential diagnosis of the condition was at times a matter of extreme difficulty one could not fail to be struck by the universally accepted prevalence of the malady, even allowing for the fact that errors might arise. Particular attention should be paid to subjective symptomatology, which might vary from a trifling degree of effort syndrome to serious manifestations of circulatory embarrassment, giddiness, breathlessness, and physical fatigue. In a large number of cases retrosternal pain would be complained of as a prominent symptom; its later recurrence must always be viewed with alarm. A comprehensive study of physical signs was essential to correct understanding of the course of the disease. Unfortunately, there was no reliable method of estimating the functional capacity of the heart in anything approaching a concrete form. For these reasons every case should be investigated on its individual merits, obvious discrepancies being noted and their significance assessed. Well-known signs of circulatory incompetence might proclaim their presence in unmistakable fashion. He had notes of several cases in which a relative asystole, observed by x-ray examination, proved to be a valuable sign of developing atheroma. Another sign was cardiac arrhythmia, to which special attention must be devoted. Some 50 or 60 per cent. of all cases of coronary thrombosis were immediately fatal; a relatively small number of patients recovered completely, and the remainder, roughly 40 per cent., might be expected to make a partial recovery. Their prognosis might be determined to some

extent by careful investigation of the circulatory efficiency and its reserve capacity, always remembering that complications might develop in a disease the pathological basis of which was coronary atheroma associated with myocardial dystrophy.

Sir MAURICE CASSIDY said that there was one factor which he thought was important in producing a coronary thrombosis or thrombosis elsewhere than in the coronary circulation—namely, infection. There could be no doubt that many thromboses were infective, and probably the fever and leucocytosis which were seen so often in coronary thrombosis were part of the evidence of its infective nature. This was a factor that could be modified by suitable treatment, sometimes with very satisfactory results. He agreed that the electrocardiogram was very disappointing so far as prognosis was concerned. Serial electrocardiograms, with the noting of progressive changes in the myocardium, might afford valuable information, but he did not think that a serious prognosis ought to be based entirely on electrocardiographic changes.

Dr. EVAN BEDFORD said that post mortem it was frequently found that the heart was blocked by a recent thrombosis, with nothing to be seen in the myocardium at all. It was these cases which were so often the subject of coroners' inquests; they formed a large percentage of all cases of coronary occlusion. The next most common thing found post mortem was hearts with healed fibrous infarcts, and the rarest thing to find at necropsy was infarcts of less than two months' duration. The type of case which accounted for the heaviest mortality was one which was rarely seen clinically. The question was, on seeing clinically a case of coronary thrombosis, what to say to the anxious relatives. The truth was that during the acute stage no one could give a prognosis, though the chances were three to one in favour of recovery from the attack. People who died suddenly after an attack of coronary thrombosis often died within the first twenty-one days, and when the patient had survived that period his chances might be said to be definitely better. It was not always the patient who lived longest who had the best health; sometimes people lived for several years in a most precarious condition. Persistently low blood pressure indicated that the myocardium as a whole was insufficient—that is to say, probably the infarct was very large, and therefore the outlook was bad.

Dr. T. S. KEITH said that out of the last 200 coroners' post-mortems in which he had been interested, 111 revealed cardiac conditions, and of this number fifty-one cases showed definite diseases of the coronary artery. Twenty of these had generalized atheroma, and the remaining thirty-one had either an infarct or a clot. The most interesting point was the previous history of these coronary cases. In twenty of them there was no history whatever—the man was found dead and there was no story of previous illness; in nine of the remaining cases the deceased person had complained of indigestion, and had had treatment of some sort; six had had shortness of breath for a matter of months before death. Only two had any story of heart disease which had been diagnosed as such. Sixteen of them had fibrous infarcts, but in spite of that no cardiac history beforehand. Professor PLESCH said that so long as all angina and coronary troubles were regarded as the same not much progress could be expected in either prognosis or diagnosis. He pleaded for a more discriminating study of the arteries. It was most desirable to build up a better understanding and a more widely recognized pathology of angina pectoris. Dr. PHILIP ELLMAN asked a number of questions. What was the relative prognosis in coronary thrombosis when there was clinically a comparatively healthy heart and when clinically there was a diseased heart? What was the relative prognosis with and without cardiac aneurysm? What was the significance of the persistent Q wave in these cases?

Professor HAY, in reply, said that to make a statement as to the prognostic significance of aneurysm would require a very much larger number of recorded cases than were available at present. The only significance of a persistent

Q wave was that it might help in diagnosing the previous existence of coronary thrombosis; it had no prognostic value. As for the prognosis when coronary thrombosis occurred in a healthy heart, he could only say that it was most unlikely to occur in a healthy heart, unless due to embolism. On the general question, as to the attitude to be adopted towards inquiring relatives, he thought that during the acute attack one could only talk of possibilities; after the acute attack, probabilities might be discussed. He hoped there would be another discussion in the Section in five years' time, when this whole subject, which was now perhaps a little premature, might be approached with greater confidence.

THE ANAEMIAS AND THEIR TREATMENT

At the Medical Society of London on October 22nd, with Dr. HOPE GOSSE in the chair, a discussion was held on "The Anaemias and their Treatment."

Dr. LESLIE WITTS, in an opening paper, traced the work done since 1926, in which year several noteworthy contributions were made, including that of Minot and Murphy on the treatment of pernicious anaemia by special diet, establishing the curative properties of liver. The merit of these authors in discovering the liver treatment had rather overshadowed their work on the reticulocytes, which had made possible a useful means of assessment of the value of therapy in various types of anaemia. Of anaemias due to defects of diet he gave two examples: the nutritional anaemia of infancy and tropical nutritional anaemia. The most important anaemias due to condition deficiencies, apart from pernicious anaemia, were sprue and idiopathic steatorrhoea. Since 1926 the nutritional aspects of anaemia had preoccupied the attention of clinicians and research workers, but the first-fruits in this field were quickly gathered, and attention was now directed to the way in which the ripening of the blood cells might be inhibited by infection and other agencies. The effects of infection on blood formation were complex; for example, it had a definitely inhibitory effect upon the utilization of iron. The inhibition of the ripening of the red cells by infection was well seen in syphilitics artificially inoculated with malaria, also in those suffering from natural malaria. Among unusual anaemias was a striking one produced by the ingestion of radium salts; this had been seen in girls engaged in painting luminous watches and accustomed to point the brushes with their lips. After giving other examples, Dr. Wits said that it was evident that in addition to anaemias due to increased destruction of blood, as from haemolysis and haemorrhage, and those due to chemical and bacterial poisons, there was a third and most important group, due to disturbances in the growth of the red cells, and in which the marrow, although perhaps anatomically extensive, was functionally ineffective, delivering few cells into the circulation. The cause was most often an insufficient supply of materials for blood formation, either through faulty diet or alimentary disease, but it might be an inhibition of the utilization of the raw materials by infection, toxic substances, or malignant disease. Drugs which contained the benzene ring were potent agents in producing agranulocytosis, and this condition might be expected to be more frequent with the wider use of these forms of medication. The same general principles as applied in diseases of the red cells applied also in leucopenia. Dr. Wits concluded by saying that there were few fields in which the relation between nutrient factors and orderly tissue development could be seen so clearly as in the haemopoietic system.

Dr. F. J. POYNTER, who mentioned incidentally that Galen used liver for the treatment of anaemia, asked a question concerning remissions. Some years ago he saw a young girl with secondary anaemia who did well on ordinary treatment, but came back to hospital nine months later with a profound anaemia of the pernicious type. Her red cells diminished to between 500,000 and 750,000. At that time liver treatment had just been established, but she was too ill to take liver, and appeared moribund. Then, without liver treatment or drugs, she

showed some improvement, was able to take liver, recovered, and was well for several years, dying eventually of pulmonary tuberculosis. It was difficult to understand a condition which presented such a picture.

Mr. ZACHARY COPE said that anaemia troubled the surgeon as well as the physician. He recalled the case of a boy who had pelvic peritonitis resulting from appendicitis, and it was necessary to perform enterostomy. This served for a time, and then the inflammation spread up the gut, and it was necessary to do an enterostomy higher up. The patient was extremely toxic and collapsed, but he got over it, and two years later developed anaemia of the pernicious type. Was it possible that the toxæmia might in some way have affected the liver or bone marrow, leading to pernicious anaemia? He responded to liver treatment for about a year, but ultimately died two years after the onset.

Mr. EARDLEY HOLLAND said that anaemia also interested the obstetrician and gynaecologist. The simple anaemia of pregnancy seemed a very common thing, and he wondered whether it might not fall into the category of nutritional anaemias. Not all the simple anaemias of pregnancy, however, were nutritional, for sometimes they were found in women who lived extremely well. It was a common fallacy that meat was not good for the pregnant woman, and some anaemias might be traced to abstinence in this respect. At about the age of the climacteric irregular and profuse menstruation often occurred, and it was frequently supposed that the anaemia was secondary, but that was not necessarily so; some of these patients had a primary anaemia. Dr. F. PARKES WEBER asked as to the frequency of aplastic anaemia. He had once seen a case of acute aplastic anaemia in which there was no opportunity to do transfusion. The patient died, and the bone marrow, examined post mortem, was found to have practically no red blood-forming tissue left. This type of anaemia seemed to be exceedingly rare. Many cases supposed to be of aplastic anaemia were of an atypical disease allied to leukaemia.

Dr. G. W. GOODHART said that he had been "horrified" by the advice given by the Ministry of Health that small infants who were anaemic should be given doses of iron with their food. This seemed to him unbiological. The proper thing was to give iron through the mother, not some iron salt to the infant by mouth. He also mentioned that the large majority of women who had anaemias after abortion did not need transfusion; they did perfectly well on ordinary treatment with iron. Mr. V. B. GREEN-ARMYtage referred to megalocytic anaemia found among young women returning to this country from the Tropics. Liver was practically useless. The only treatment he knew of in such cases was marmite. If in the case of these pregnant women a blood transfusion was done, and more than 100 to 200 c.cm. of blood was given, they practically always had an abortion or premature labour.

Dr. P. H. MANSON-BAHR discussed some tropical anaemias, including the anaemia associated with ankylostomiasis. It was said that worms of the *Ankylostoma* genus were the most potent source of anaemia in the Tropics, but there were natives in the Pacific Islands heavily infected with ankylostomiasis who showed no signs of anaemia. The anaemia did not appear if the people were well fed and well housed. With regard to the history of liver therapy, he mentioned that Sir Patrick Manson, who discovered sprue in 1880, was in the habit of giving liver in sprue anaemia, and said that he got the idea from the Chinese, who attributed it to Confucius. Dr. W. BURTON WOOD described a patient who was quite symptomless, but whose white count remained obstinately low notwithstanding all kinds of treatment. Was this likely to be a case of agranulocytosis?

Dr. WITTS, in reply, said that the remissions which occurred in the pernicious and other forms of anaemia might be attributed to changes in gastro-intestinal function. In many nutritional and metabolic disorders, such as rickets and scurvy, similar remissions were noted. Any gross disease of the small intestine might easily lead to severe anaemia, and to remove more than six feet of the small intestine was inviting trouble in the future. The

idea that meat should be cut down in the diet of the pregnant woman was a fallacy which ought to be combated strongly. There would be far less anaemia and chronic ill-health in pregnancy if the mother was better fed. It had to be borne in mind that she had to give iron to the foetus which would serve the infant until weaning, for iron was not given to any great extent in the milk. He did not know why Dr. Goodhart should be horrified at the idea of giving iron to infants. He was not so certain that the feeding of the mothers would preserve the children from anaemia. The majority of children took iron quite well. He agreed that aplastic anaemia was a very unusual disease; at Guy's two or three cases were seen in a year. Transfusion was much too readily resorted to nowadays; it was a more dangerous operation than was generally supposed. With regard to the treatment of patients with chronic leucopenia, he usually put them on a diet with plenty of vitamins and plenty of such foods as sweetbread, liver, and kidneys, and was extremely careful to inquire into their history and the possibility of their having taken any toxic drugs. Beyond advising general hygienic measures and care to avoid as far as possible intercurrent infection, there was not a great deal to be done.

MEDICAL SERVICES AT HOME AND ABROAD

At a meeting of the Royal Society of Tropical Medicine and Hygiene at Manson House on October 18th, with the president, Sir LEONARD ROGERS, in the chair, Professor W. W. JAMESON read a paper on "The Medical Services at Home and Abroad," in which he recounted his impressions gained from a tour of India, Ceylon, and Malaya.

As a background Professor Jameson gave in outline the history of the public medical service of Great Britain from its beginnings just one hundred years ago, when the reformed Poor Law gave England its first general medical service, to the present day, with its public health service founded on sound sanitation, and aiming at the improvement of conditions of living throughout the country and the raising of the general level of health of the community by every available means. In India and in most of the Colonies official medical services owed their origin either to some form of military medical organization or to the need for medical care for European residents. Only in comparatively recent years had attempts been made to extend the benefits of public medical services to native populations. The early bias towards curative medicine was reflected in the costly hospital system established in many parts of the Empire, making undue demands on the money available for medical services, but having little effect on disease prevention or on the raising of the general standard of hygiene in the Tropics. The importance of establishing medical schools in suitable centres had been universally admitted. From them would come the medical officers who would one day form a large proportion of the medical staffs of the Colonies. Such schools gained from close association with Government institutions, but should be given as large a say as possible in the management of their own affairs, and not be regarded merely as a division of the Government medical department because they were paid for out of local revenues. It was now realized that maternity and child welfare work was best carried on as part of a general public health programme. Malaria and the diarrhoeal diseases as the chief causes of infant deaths must be got rid of if the high infant mortality rates were to be reduced. Improved sanitation was the real remedy. Better midwifery required the provision of trained midwives in selected areas, their registration and supervision. This was being achieved in parts of Malaya. In India the problem was unbelievably difficult in rural areas. The tendency was to diffuse effort over too wide an area. Maternity and child welfare work must be concentrated to be successful; to give a certain amount of training to a native midwife and then send her out to practise without supervision was of little or no value. Midwives and

health visitors must be public health "missionaries" first and foremost.

The value of active preventive measures against leprosy was now recognized; mere segregation of infective cases was no longer considered sufficient. Ceylon's scheme of a leprosy survey, involving careful records of cases, examination of family contacts, and supervision of non-infective cases by the public health staff, offered great hopes of success. Tuberculosis, now as serious a killing disease in parts of the Tropics as in Europe, called for more accurate information. Work on the lines of that carried out by Scott in Hong-Kong, by the Rockefeller Foundation in Jamaica, and by Wilcocks in East Africa was needed as a preliminary to any special action in the East. All other tropical diseases dwindled in comparison with malaria. The amount of man-made malaria due, for example, to uncontrolled jungle clearance or to engineering work carried out without consultation with the medical department was astounding. It was unfortunate that information made available by the Malaria Survey of India had not been put to more practical use by the public health departments in India itself. The impression gained in India was that too much attention was paid to arrangements, never adequate, for the wholesale distribution of quinine, while measures directed against anopheles took a second place. In striking contrast was the attitude of managers of many commercial undertakings in India, Assam, and Malaya to antimalarial work. Some of the railways, some of the gardens in Assam, and some of the rubber estates in Malaya, where there was close co-operation with the Government medical department, were an object lesson in the much-vaunted co-operation between science and industry. As regards general sanitation, upon which the control of so much tropical disease depended, there seemed a tendency in some quarters to prefer methods of control based on laboratory findings to sound sanitary measures. Anti-typhoid, anticholera, and antiplague inoculations had a place in preventive work, but good sanitation was a permanent safeguard. The need of India particularly, from this point of view, was good sanitary engineering, and plenty of it.

The organization of medical services at home and in India presented striking contrasts. In England the bulk of public medical work was directed by whole-time medical officers of health, appointed with the approval, and not dismissible without the consent, of the Ministry of Health, which in its turn maintained a technical staff whose services were available to local authorities in cases of difficulty. India had no comparable organization. Unfortunately there was no provision in its constitution for a strong central department with health as its concern. The Public Health Commissioner with the Government of India works practically single-handed at New Delhi with very limited official right of entry to any of the Provinces. The Indian Medical Service was based essentially on the military needs of the country, and lacked the necessary flexibility for civil administration. It had been allowed to develop rather on clinical lines, and the old-established custom of allowing private practice still held. Most of the large medical schools in India had special institutes for the training of post-graduate students in public health, but at least two of those visited were conducting no such courses of instruction owing to lack of demand for health officers. It was to be hoped that the All-India Institute of Hygiene, recently opened in Calcutta, would stimulate India to fresh efforts by training men and women for public health appointments in that country.

Progress in the medical services in the Colonies had been most marked since the war. The regulations of the recently unified Colonial Medical Service envisaged a service of whole-time officials whose primary duty was to the State, and no entrant to the service would be entitled to a right to private practice. In Malaya and Ceylon a real attempt was being made to hold a proper balance between the claims of curative medicine and of sanitation. Most Colonies now trained sanitary inspectors locally, and to assist in this and to relieve medical officers of a good

deal of work experienced European inspectors were needed. As an encouragement to young medical men to undertake service abroad it needed to be made known that conditions were good, that abundant opportunities for original work offered themselves, and that the standard of professional work was often as high as at home. The quality of the laboratory work done was admirable, but the wisdom of keeping a man too long on research work in the Tropics, away from contact with fellow research workers in his own and similar fields, was questionable. Here was a matter for the Medical Research Council to consider now that their sphere of operation had been made Empire-wide. Perhaps it was too much to envisage for the future a Government medical service which would include within its scope service over-seas as well as service at home, but the result would be well worth any expenditure of effort in overcoming the administrative difficulties.

DISCUSSION

Sir JOHN MEGAW said that England's sanitary victories were achieved because of public co-operation, and because the economic standards of life were improving as the work of disease prevention was proceeding. The example of Japan, where magnificent public health efforts had not achieved success, was more applicable to India, and showed that the new wine of scientific sanitation could not be poured into the old bottles of antiquated custom. Modern sanitation was obviously a mockery to people who were ill nourished, and, as long as the provision of the necessities of life did not keep pace with the reproduction of children, must remain so. The public health officers belonging to the I.M.S. had not organized a co-ordinated policy of public health for India because they had been deprived by the administrative system of India of even the limited influence they once had in the affairs of the central Government. More than twenty years ago the late Sir Pardey Lukis had put forward an admirable scheme for a public health organization for the whole of India which had good prospects of being taken up by Government, but the war came and stopped everything.

Sir MALCOLM WATSON said that when criticizing the I.M.S. one must remember that the Indian Government itself had never put the public health of the people first. The I.M.S. perhaps had its greatest opportunity thirty or forty years ago, but at that time the civil service and the military service in India were more concerned with the first duty of a Government, which is to preserve peace. In Malaya peace was never a problem, so that health had been the concern of the Government from the beginning, and it had been prepared to hand out money in a most generous way for sound health purposes.

Surgeon General P. J. KELLY said that he had found in British Guiana that it was easier to educate and to instil public health measures in races such as the descendants of African slaves, without long years of culture, than in races such as the Indians, with a culture of their own. Dr. A. R. PATERSON thought that to form and influence the policy of Governments it was necessary to get across to them somehow a knowledge of the actual condition of the peoples in the Tropics—how truly appalling it was—and that nothing in the way of maternity services, health centres, etc., was going radically to alter that condition. Group Captain H. E. WHITTINGHAM instanced the wide-awakeness of the Colonial Medical Service in sending a certain number of Colonial medical officers to the Royal Air Force for special training in aviation medicine.

Sir RICKARD CHRISTOPHERS pointed out that the money available for public health in India was too small for anything at all to be done in India, of the type of public health work done in England, without the most careful thought and knowledge and continued policy. He agreed that there was no prospect of any permanent benefit in India, except through what Professor Jameson had spoken of as somebody doing the driving. Sir LEONARD ROGERS said that the ordinary expenditure in India for the whole of the work—teaching, hospitals, schools, and sanitation—had to come from an income of two or three shillings per head of population.

DENTAL PROBLEMS OF MEDICAL INTEREST

At a meeting of the Liverpool Medical Institution on October 18th, with the president, Dr. J. MURRAY BLEIGH, in the chair, Mr. ROBERT KENNON read a paper on "A Few Dental Problems of Interest to the Medical Profession."

He said that whereas caries was often considered to be the result of starch and sugary food, the modern child was indulging in far more sweets than formerly in order to combat acidosis. Serious infection from the teeth was rare in childhood, apart from concurrent infectious fevers, when the mouth should be watched carefully for development of caries. In adults acute pulpitis might lead to extensive osteomyelitis. More frequently the apical abscess had led to decalcification of bone over a long period of time, so that cortical sequestra were more common. The fact that the molar roots were beneath the mylohyoid ridge meant the early approach of abscesses to the neck, and these should be opened before extensive cellulitis had developed. In dental cysts the whole sac should be removed. In trismus gags were necessary, and relief might be obtained by a spring over the head pressing lightly upon the infected joint. Ill-fitting dentures were a source of leucoplakia and carcinoma. The life of a denture should not be more than five years.

Mr. J. A. WOODS agreed with Mr. Kennon as to the importance of retaining deciduous teeth when possible. The early loss might in some cases seem an immediate gain, but it frequently led to serious irregularities later on. He stressed the great importance of normal breathing, and pointed out some of the evils seen by the dental surgeon in "mouth-breathers." He had found that an abscess caused by the upper lateral incisors frequently caused oedema on the palate (and from a development point of view that was easily explained); on the other hand, an abscess from the upper central incisors more frequently caused oedema in the sulcus of the lip. He quite agreed that where a large number of extractions was necessary it was very important that it should be done in several stages. The more septic the mouth the more important this became.

Mr. J. COSBIE ROSS pointed out the occurrence of large sequestra in the region of the mental foramen of the mandible, following an alveolar abscess of the posterior molar. Normal bone was present in these cases between the original alveolar abscess and the residual sequestrum, and it was possible that thrombosis of the inferior dental artery, and the subsequent diminution of blood supply to the bone, was the cause of the necrosis. Mr. ROSS also emphasized the association between the wearing of ill-fitting dentures and carcinoma of the mouth, and the appreciable percentage of cases where a definite causative relationship could be established. He quoted one case where a man had worn a very large denture for eighteen years, during which time an indurated crack had developed at the corner of the mouth on both sides owing to excessive stretching of the mouth required to permit the denture to be removed. When this case was seen by the speaker recently an epithelioma (confirmed by microscopical section) had developed at the site of the crack on both sides.

Mr. A. E. BURROUGHS drew attention to the connexion between dental caries and inflammation of the ciliary body, cyclitis. This was an extremely obstinate, deep-seated inflammation, due to sepsis, and one of the first foci to be thought of was in the teeth. If dental caries was the cause the case should be referred to a dental surgeon for investigation. In these cases dental treatment would generally cause the cyclitis to clear up quickly and an eye be saved which would otherwise surely be lost. Dr. RAWDON SMITH stressed the importance of team work, and agreed that adrenaline more often caused trouble than cocaine or one of its derivatives. He further thought that reactionary haemorrhage was more common after local than after general anaesthetics. He was glad to know that dentists were becoming more conservative by not agreeing to wholesale extractions in cases of chronic rheumatism.

Dr. G. GRAHAM MACPHEE said that he remembered when glucose, and particularly glucose in cheap sweets, was considered to be the chief factor in dental caries, yet nowadays glucose appeared to be regarded as an essential constituent of the diet of the growing child. Perhaps both views might be reconciled if the necessary glucose and sweets were eaten only at meal-times and the teeth cleaned immediately afterwards. Dr. Macphee said he was glad that Mr. Kennon had stressed the importance of alveolar abscess. There certainly were cases where removal of the offending tooth was not indicated, but in most cases if the tooth concerned was unsavable it should be extracted at once, without "waiting for the swelling to go down." He instanced a case with a history of discharging external sinus of eighteen months' duration which was cured by extracting two septic roots; yet although five doctors had treated the case nobody had looked inside the mouth. Dr. Macphee then showed slides of radiographs which proved deposition of new bone in the apical region of two upper lateral incisors after appropriate root-canal treatment. He could not agree that post-extraction haemorrhage did not occur after a general anaesthetic had been used, having seen two cases in hospital only that afternoon. In the treatment of true dental cysts he had obtained good results by simply removing one wall of the cyst and bringing the buccal mucous membrane into apposition with the epithelial lining of the cyst. Dr. Macphee felt sure that all dental surgeons would agree with Mr. Kennon that dentures should be renewed more frequently. Patients did not realize the harm that might be done by dentures which no longer fitted their shrunken gums. A particularly pernicious practice was to continue wearing temporary dentures long after they had ceased to fit. Here again was an opportunity for more co-operation between physician and dental surgeon.

Professor HENRY COHEN also supported the plea for closer co-operation between general medical and dental practice. Many diseases had oral presenting symptoms. Six cases of adult scurvy had applied to the Dental Hospital for treatment in the past three to four years. Emphasis should be laid on the part played by the salivary glands as excretory organs for the products of intestinal putrefaction, especially of indoxyl compounds, which were responsible for the stains often seen in the molar region of an upper denture in the constipated female. A simple support in facial paralysis could be made from a pipe-cleaner and inner-valve tubing, bent so as to hook round the affected angle of the mouth and ear on the same side.

MANGANESE POISONING

Dr. DONALD OWEN, in a short paper on "Manganese Poisoning," first outlined the various commercial uses of manganese, and gave a brief description of the manufacture of the metal and its separation from other ore. The history of chronic manganese poisoning dated back to 1837, when Couper described five cases. Only fifteen cases had been recorded up to 1913, and these were found in France, Germany, and the United States. Esdall in 1919 reported further cases, but it was not until 1922 that the first publication on this subject appeared in our own literature, by J. R. Charles of Bristol. The pathology was practically unknown, and animal experimentation had failed to assist, with few exceptions. Findlay was able to produce cirrhosis of the liver in rabbits, and Mella changes in the corpus striatum and globus pallidus of monkeys, following administration of manganese chloride. In June and July, 1934, the speaker saw four cases of chronic manganese poisoning at the Bootle General Hospital, occurring in men working in the same manganese works. The appearance of symptoms of intoxication to the metal was in one case after only eight months' work, and in the other three after two and a half, six and a half, and eight years respectively. The clinical picture in each case was indistinguishable from that of chronic post-encephalitic Parkinsonism, but the extent of involvement of the extrapyramidal system varied in each. Signs and symptoms of hepatic cirrhosis were not found.

CORRESPONDENCE

Treatment of Haemoptysis

SIR,—I was pleased to see Drs. Morlock and Pinchin's condemnation of the use of morphine in the treatment of haemoptysis (*British Medical Journal*, October 27th). At final examinations in medicine, candidates, when asked about the treatment of haemoptysis, invariably reply that they would inject morphine. If further pressed they may mention calcium lactate, and then seem to be at an end of their resources. In my experience the most effective immediate remedy for haemoptysis is the sub-cutaneous injection of 1 c.cm. of pituitrin. My house-physicians use it as a routine method in cases brought to hospital, and rarely have any trouble from recurrence. It is surprising that its use is not more widely known. It is not mentioned in textbooks. In the *Extra Pharmacopoeia*, under the heading of "Pituitary," there is a reference to an article of mine in the *Clinical Journal* (January 24th, 1923). At first sight a drug which raises systemic arterial pressure would seem contraindicated; but we know little about the action of drugs on the pulmonary circulation. Pituitrin is said to lower the pressure in the pulmonary vessels. In the treatment of haemoptysis it has the great advantage of being a drug usually carried in the practitioner's bag, and therefore available in an emergency.—I am, etc.,

Birmingham, Oct. 30th.

W. H. WYNN.

Congenital Pyloric Stenosis

SIR,—On reading the excellent article by Dr. H. L. Wallace and Mr. L. B. Wevill, analysing 145 cases of pyloric stenosis (*Journal*, June 30th; p. 1153), we were surprised at the high mortality rate recorded therein, and therefore decided to analyse a series of our own cases to see how the various features of the disease compared with those recorded by Wallace and Wevill. We have collected and tabulated a series of 120 cases, operated on within the last ten years; fifty-six were operated on by one of us (P. L. H.) and sixty-four by the other (L. G. T.). Most of the cases were operated on at the Royal Alexandra Hospital for Children, Sydney, N.S.W.

Out of the total number of cases there were ninety-five males and twenty-two females, the sex not being stated in three. The average age at time of operation, which generally coincided with the age at which the diagnosis was made, was 5½ weeks. The average weight at time of operation was 7 lb. The average age at which the projectile vomiting appeared was 3 weeks, the range varying from birth to the age of 11 weeks. Visible gastric peristalsis was present in all; as this is such an unequivocal diagnostic feature it was not considered necessary to determine the presence of a tumour. No case has been included in the series in which the diagnosis was not confirmed at operation. There were five deaths in the 120 cases, a mortality of about 4 per cent.

We consider that gastric lavage should be carried out in every case immediately before operation, otherwise infants will be lost either at or immediately after operation, owing to asphyxia from regurgitated stomach contents. Most of our patients were given saline solution per rectum soon after operation, and this was repeated at four-hourly intervals as long as seemed necessary. In most instances the infants were placed in a specially warmed shock ward immediately after operation, and were given breast-milk from a spoon or pipette as soon as they could swallow. The simple Rammstedt method without modifications was the operation in every instance. The operations were all done under general ether anaesthesia, and this was usually given by a resident medical officer, who had had

no special experience in administration of anaesthetics beyond the experience gained by a short period of residence in hospital. The majority of the cases were operated upon as soon as possible after the diagnosis was made, and very rarely was any special preliminary treatment given, excepting gastric lavage, as mentioned before.—We are, etc.,

P. L. HIPSLEY, M.D., F.R.A.C.S. Sydney,
Honorary Surgeon, Royal Alexandra Hospital for
Children, Sydney.

L. G. TAIT, M.B., Ch.M.,
Honorary Assistant Surgeon, Royal Alexandra
Hospital for Children.

Sydney, Australia, Sept. 29th.

* * The writers of this letter have submitted tabular records of the cases operated on by them.—Ed., B.M.J.

Ether Convulsions

SIR,—The spasmodic correspondence about ether convulsions goes on without apparently providing any real conclusions, and I take this as my excuse for writing to you. Though not an anaesthetist, I have had some experience of giving ether, first of all in New Zealand; and then from time to time I have had to give it over here.

In some 1,000 cases in which I gave open ether in New Zealand, either by the drop method or with Shipway's apparatus, I never saw anything suggesting convulsions; and I never, while I was in practice there (some four years), heard of anyone else doing so. At first in England I also never saw any suggestion of them so long as I used the procedures I was accustomed to—namely, drop-bottle alone or a Shipway worked by a bellows. Lately, however, I had begun to use oxygen with a Shipway, and on two occasions I saw definite facial twitchings. Fortunately, neither case went further. The coincidence of the appearance of the twitchings with my first use of oxygen instead of air struck me forcibly; so on the second occasion I used CO₂ as well. Again it may have been only coincidence, but with pure oxygen twitchings appeared; on changing to CO₂ they went, but returned once more with the oxygen. It really seemed as if they were heralded each time by the appearance of a bright pink colour.

Naturally one can place very little confidence in observations on only one case; but it has been noticeable in the previous correspondence that oxygen is always used. Some writers have queried its responsibility, only to rule it out as being of good quality, etc. May not the cause lie in the three factors—susceptibility, ether vapour, oxygen above the content of atmospheric air?—I am, etc.,

London, S.W.13, Oct. 24th. L. A. RIDDELL, F.R.C.S.

Motor Backache and Neuralgia

SIR,—The letter on this subject from "G. H. A." is most interesting as it describes a condition that has been very common in recent years, and with the increasing popularity of motoring is likely to be a frequent cause of disability.

I agree with "G. H. A." that the bucket-seat, so popular in all cars to-day, is the cause of the trouble, and he would add greatly to the value of his letter if he can suggest a type of seat that will retain the advantages of the adjustable bucket-seat and at the same time allow the muscles in the lumbo-sacral region to relax during a long drive. My own observations suggest that such a seat must be deep enough to support the thigh, and by means of "wings" that grip the pelvis prevent tilting and rotation in the lower lumbar vertebrae when cornering.

It may be that a seat with these features is already on the market, and "G. H. A." would be doing a great service to the motoring public and the motor designers if he will give his experience.—I am, etc.,

Shrewsbury, Oct. 29th.

B. A. ASTLEY-WESTON.

SIR,—The letter of "G. H. A." regarding motor backache in the *Journal* of October 27th (p. 791) prompts me to write this. During the last two years I have done 40,000 miles in a popular 9-h.p. saloon car, in both town and country work and long-distance journeys, the longest being 490 miles in fourteen hours, with stops only for petrol and oil. During that period I have never yet experienced any undue fatigue or backache. I attribute this to the type of seat I have. It is a bucket-seat, with a back practically upright. It has an air cushion not very tightly inflated, and with the front edge slightly higher than the rear edge. I sit square in the middle of the seat, leaning neither to one side nor to the other, with the lower part of the spine pressed against the back of the seat, and the result is that my whole spine is comfortably supported in its entirety.

The point I would stress is the importance of sitting erect and not slouching, as one sees so many drivers do nowadays. Some cars I have driven have given me backache within a few miles due to faulty seats.—I am, etc.,

Liverpool, Oct. 27th.

T. W. G.

Residual Infection of the Jaws

SIR,—Is not the picture painted by Mr. A. M. Nodine in your issue of October 20th badly out of perspective? The occasional occurrence of residual bone infection and the advantages of so-called "surgical" removal of teeth in certain cases have long been recognized by the dental profession; but to suggest that "teeth that are removed by the ordinary pulling method" (as he contemptuously terms it) "in most cases only stir up the infection . . . while the infecting process continues undisturbed" is surely gross distortion of the facts of everyday experience.

The vast majority of infected teeth are removed by forceps, with a minimum of trauma, often under gas-and-oxygen anaesthesia, the "whiff" in the hands of a competent anaesthetist extending to whatever length of time the dentist may need for the careful and deliberate execution of his work, and usually the expected relief of symptoms is obtained.

To substitute for a comparatively simple operation, as a routine method, one much more extensive and severe, and often involving painful and prolonged convalescence, would hardly seem to be in the best interests of patients generally. A good case is marred by over-statement.—I am, etc.,

London, W.1, Oct. 29th.

J. H. BADCOCK.

SIR,—Mr. A. M. Nodine's letter on residual infection of the jaws seems intended to give the impression that extraction carried out with the forceps is an unsurgical procedure, calculated to leave in the majority of cases an aftermath of residual infection. If this is his contention I feel that it should not pass unchallenged, but that the medical profession should know that this opinion, which is held by a relatively small body of American ultra-specialists, is not accepted by the majority of dental surgeons in this country, whether engaged exclusively in general practice or on the staff of teaching hospitals, and therefore having special facilities for, and experience in, that side of dentistry which borders on "oral surgery." There would seem to be two main points in Mr. Nodine's letter. One is that no tooth should be removed in the direction of its long axis, but by prising it out

sideways after the removal of the entire outer bony wall of its socket, and thereafter trimming away the resulting sharp corners of bone and stitching the gum over the wound. The other point is that where a tooth is removed because it is infected, either through pyorrhoea or because it is apically septic, the zone of infection in the surrounding bone should be removed in its entirety at the same time.

With regard to the first point, surely the best method of removing a tooth is that which combines the greatest ease and simplicity with the minimum of trauma, both local and psychic, and the absence of undesirable sequelae. A considerable proportion of dental extractions can be performed in a few seconds with the forceps under local or general anaesthesia, with little force beyond that required to rupture the periodontal membrane, with no damage to, or loss of, surrounding bone, and with such complete absence of after-pain that the patient is only reminded of the extraction by the consciousness of the gap left. When difficulty is expected more elaborate methods may be used in order to avoid bruising of the bone and gum, and such methods may vary from the preliminary separation of divergent roots to the removal of less or more bone, even up to the full rigours of Mr. Nodine's operation; though the last, I contend, is only rarely necessary.

That this more conservative method of dealing with the teeth is justified by the results is exemplified, in the case of impacted wisdom teeth, by the lessened after-pain and greater rapidity of healing which follow removal by deliberately splitting the tooth into pieces, which can be taken out without the extensive cutting of bone which would be necessary to permit its removal whole. Nor must the time factor be ignored. When general anaesthesia is used the advantage of rapidity is obvious; where a local injection is preferred a more or less prolonged operation, under presumably aseptic conditions, is a considerable ordeal as compared with extraction by forceps, equal skill being assumed in each case. With regard to shaping a suitable bony base for dentures, it is true that the "surgical" method offers certain advantages, but the same end is attained by the simpler and quicker method of trimming away the sharp margins of the socket after extracting the tooth.

Mr. Nodine's second principle relates to the removal of infected bone. It would be of interest to know how Mr. Nodine determines the precise extent of infection in a given case, and whether he removes all this bone and a trifle more to be on the safe side, and whether in the case of infected bone near the antrum he has the courage of his convictions and removes it even at the expense of opening the antrum. I feel that in the last case he would do what most of us do in this and other cases—he would leave the infected bone there, and trust Nature to deal with it *secundum artem*. Does she not do so in the case of osteomyelitis of the long bones once drainage is established, and in the case of an incised boil? (Or should we excise boils completely, and save Nature any responsibility in the matter?)

My reference to the antrum is not frivolous. I have had the opportunity of examining microscopically a large number of sections of human maxillae showing the molar teeth *in situ*, and noted that a quite moderate degree of pyorrhoea led to round-celled infiltration of large tracts of bone, extending frequently to the near neighbourhood of the antral floor.

If Mr. Nodine could show that, in a high percentage of cases treated by simple extraction, infected areas of bone persist for a long time, to the detriment of the patient's health and comfort, I think he would have a strong case for removing bone where radiographs show it to be abnormal, though it must be remembered that up

to the present we do not know with certainty how to interpret many of the abnormal x-ray appearances of alveolar bone, though work on these lines has been commenced in the Hale Research Laboratory of the Royal Dental Hospital. I submit that so far clinical evidence is all the other way; the great majority of edentulous alveoli give rise to no reasons, local or otherwise, for suspecting trouble within, and experimental evidence is entirely lacking on either side.

It is true that areas of infection are found in edentulous jaws from time to time, and that conditions as serious as trigeminal neuralgia have been benefited by Warwick James, Bowdler Henry, and others by the removal or diathermy of such areas, but to use this fact as an argument in favour of replacing present methods by one so much more elaborate and so liable to abuse seems to me quite unjustifiable.—I am, etc.,

London, W.1, Oct. 29th.

NORMAN J. AINSWORTH.

"German Measles": A Plea

SIR,—My attention has recently been drawn to the unsuitability of the term "German measles," used to describe rubella. I believe the word originates from "germane," meaning "closely allied to." But the diagnostic differences between measles and german measles are distinct enough to warrant the use of a better name for the latter.

The use of this term is misleading to the public in many ways. It confuses in their minds a comparatively mild infection with one which may be serious. It also leads to a false impression as to immunity. The parent vaguely knows that a child has had "measles of some sort or other, German or English, I don't know which"; and therefore has a false sense of security and thinks him adequately protected against further infection with either disease. I have even heard of practitioners not troubling to differentiate between these different diseases, leaving the parent in ignorance.

Cannot the medical profession lead the way—educate the public—by themselves consistently using the word "rubella," or by fixing upon some other suitable name? Surely the usage of the term "German measles" by medical men and women is far from the accuracy which should be the basis of scientific nomenclature.—I am, etc.,

Bromfield, Oct. 22nd.

G. M. L. SUMMERHAYES MACRAE.

* Unfortunately, the official *Nomenclature of Diseases*, drawn up by a joint committee appointed by the Royal College of Physicians of London (H.M. Stationery Office, 1931), gives "German measles" first, with "rubella" and "röteln" in parentheses, as admissible synonyms.—Ed. B.M.J.

Local Treatment of Coryza

SIR,—A recent recruit to the stage of medicine is the theory that a general infection is less dangerous to the organism as a whole in proportion to the extent of any local reaction it produces on an individual mucous membrane or tissue.

This *enfant prodigue* is commended to our attention by such distinguished sponsors as Lord Horder and others, and it must be said that there are strong grounds for admitting that there may be "something in it" in spite of its suspicious resemblance to our old but rather *démodé* friend the fixation abscess, or even to that old reprobate of Victorian days known as "laudable pus." The comparative safety of pneumonia with a good solid lobe and of puerperal infections with a determined parametritis are cases in point.

It would appear, however, that certain practical applications of this proposition have not received sufficient attention. For example, the common cold, that ever-present reproach. This normally attacks the nose, and admittedly makes the sufferer uncomfortable and perhaps ridiculous. It is nowadays considered *de rigueur* to attack the sufferer's nasal mucous membrane with oils, inhalations, sprays, pastes, and snuffs whereby the beneficial and harmless local reaction in the nose is greatly diminished, but a severe bronchitis or other manifestation takes its place, and may prove most obstinate, and even dangerous. As we are unable to cut it short by local means, ought we not rather to encourage and welcome a streaming cold in the nose as the best and most harmless means of overcoming the infection and producing an immunity at least for a season? If so, we must consider all local curative treatment as dangerous, and confine our efforts: (1) to promoting the general resistance, and (2) to protecting the lungs and bronchi by the means and remedies which in our experience are useful for these ends.

Similarly, it may be that the prevalence of "mastoids" in our schools might be less if, instead of doing the universal "T. and A.," we contented ourselves with removing the A. where they are causing obstruction and merely "hoovering" the T. Again, is a chlorine mixture worse than useless in typhoid? Certainly intestinal disinfectants are useless in acute dysentery.

Other similar examples of acute infections where local treatment is contraindicated or clinically useless will readily occur to mind—as erysipelas, diphtheria, meningitis—but it is towards acute coryza that I desire to direct attention.—I am, etc.,

East India United Service Club,
London, Oct. 23th.

W. C. SPACKMAN.

Alkali Reserve in Asthma

SIR,—With reference to Dr. James Adam's letter in the *Journal* of September 15th (p. 531), I may state that a condition of lowered alkali reserve (acidosis) with low blood sugar content in asthma was reported by B. C. Roy and myself in 1923 (*Calcutta Medical Journal*, March, 1923, p. 1). Since then many cases of asthma have been treated with sodium bicarbonate and glucose, often with very good results.—I am, etc.,

Biochemical Department, Carmichael
Medical College, Calcutta, Oct. 9th.

H. N. MUKHERJEE.

Concurrent Varicella and Herpes Zoster

SIR,—In connexion with the clinical memorandum on the relation between herpes zoster and varicella by Dr. Douglas Robertson, published in the *Journal* of October 20th (p. 721), a case presenting the combined appearance of the rashes of herpes zoster and varicella is sufficiently rare to warrant recording.

A mechanic, aged 31, was first seen on October 10th, 1934, complaining of shooting pains under his left arm and a rash on his chest, which first appeared on October 7th. Examination showed a typical herpes zoster, localized to the second and third thoracic segments of the left side and along the cutaneous distribution on the inner aspect of the left upper arm. The temperature was 98.4°. On October 13th the patient was again seen, when he complained of a further rash, which had first appeared on October 11th. Examination showed that in addition to the herpes zoster a further rash was present, consisting of papules, vesicles, and pustules, being thickest on the trunk, and also present on the face, scalp, proximal portions of the limbs, soft palate, and fauces. The forearms and distal parts of the legs were quite free from the rash. The temperature was 101.4°, and a diagnosis of varicella was made.

In this case there was no history of any previous exposure to herpes zoster or varicella, and if it may be presumed that the virus causing herpes zoster can infect another person and cause varicella, then it is interesting to note that this virus can presumably cause the two clinical conditions in the one person.—I am, etc.,

London, N.W.2, Oct. 19th.

M. FISHMAN, M.B., B.S.

Whither General Practice?

SIR,—While we realize that in these days of hurry and bustle it is not possible to observe many of the courtesies previously believed in, surely it is still possible for a certain degree of professional etiquette to be maintained. May I cite one of my experiences as a general practitioner?

A panel patient was treated by me for pleurisy with effusion, and was warned as to the possible underlying cause. On x-ray and further examination during convalescence no definite evidence of tuberculosis was obtained. After a holiday he was very well, and his weight was increasing. He was allowed to return to light work and was to report weekly, pending a second x-ray investigation and examination by the tuberculosis officer. After an absence of fourteen days he came to my surgery with the following information. His firm had insisted on his return that he saw another medical man. I received no intimation of the examination from the firm or the doctor. The patient, however, was told by him that he was to see the tuberculosis officer at once, and have another x-ray examination. As it happened, it was during the week in which he failed to call that I intended sending him for these examinations. His absence was explained by the fact that he had been sent for a holiday by his firm at their examiner's request.

I think it is widely accepted that there is a growing tendency on the part of the general public to criticize the abilities of the general practitioner, particularly the panel doctor. Surely, therefore, this practice of examining another doctor's patients without his consent is much to be deplored? I may add that the above case is only one of several in my own experience, and from what I have been told by other practitioners it is a fairly common occurrence.—I am, etc.,

Cheshire, Oct. 23rd.

E. M. DAVIES.

Medical Benevolence

SIR,—Dr. A. J. Hawes, in his letter to you of October 20th, gives me the opportunity, as Sir Thomas Barlow's "Assistant Tormentor," of thanking him: first for writing to you about medical charities, a form of propaganda in which we rejoice; and secondly, for being a direct subscriber to the Royal Medical Benevolent Fund (a) through our Charities Committee, and (b) via a banker's order so many years. How I wish every one of the 52,000 men on the Scottish and English Registers would do likewise: if these did his grievance would at once be abolished, and my wished-for increased subscription list would be attained.

So, Sir, you see now why Dr. Hawes has never been approached in person and asked to subscribe. We only go to the delinquents who do not attempt to do anything for their poorer brethren, and such splendid fellows as Dr. Hawes, who don't require reminders, we avoid "tormenting" as much as possible.

With regard to local secretaries, we are always asking for more help in this direction, so that the personal application which Dr. Hawes suggests can be effectively made, but I regret to say that we have only had two answers in reply to our request for local secretaries which

was sent out in the last annual report. Could he not help us in this direction?—I am, etc.,

LEWIS G. GLOVER,

11, Chandos Street, Cavendish Square, W.1, Oct. 23rd.

SIR,—It is good to see that the subject of medical benevolence is attracting more attention in your columns. Perhaps it might more correctly have been headed "The Lack of Medical Benevolence," for surely the inadequacy of support given to the leading medical charities is a blot on the profession. There are now more than 56,000 names on the *Medical Register*, and the income of the Royal Medical Benevolent Fund last year from subscriptions was £11,856. Comment upon these figures is superfluous.

The medical profession to-day provides a good living for its members, but when the cost of buying a practice, life insurance, education, and the deep dip into the banking account every few years to buy a new car are taken into account the difficulties of accumulating capital to provide for old age and the widow and orphans are obvious. From the exacting nature of our work it is inevitable that the number of those who break down in health, or die early, must be considerable. The importance of the Royal Medical Benevolent Fund having adequate funds at its disposal, with which to assist cases of necessity, is surely a duty which the profession owes to itself.

I have been impressed by three lines in Dr. Hawes's letter; he says that "in eighteen years of qualified life I have never once been personally approached and asked to subscribe to the fund." That, I believe, is the secret of the apparent apathy in the profession to the needs of the Royal Medical Benevolent Fund and other medical charities. It is the personal appeal that is necessary. What can be done is illustrated by my own experience as Charities Secretary in this Division—one of the youngest and smallest in the Association.

By personal appeal, during the five years of its existence, I have raised a sum of nearly £100 for the Royal Medical Benevolent Fund. Every practising colleague contributes, and I have rarely to ask a second time for the now recognized yearly subscription. I might add that I am careful not to make my appeal synchronize with that of the income-tax collector.

What can be done in this Division can be done in others, but the personal appeal is essential. I feel certain that it is not apathy to the needs of the less fortunate members of our profession and their dependants but the distractions of a busy life that has been the real reason for the meagre support given to our own particular charities.

The British Medical Association itself is so busy flying flags, *re* hospital policy, public medical services, and other schemes for socializing the profession, that it has little time to devote to the needs of medical charities. It would, however, do a good service to the profession if it would urge a little more vigorously upon the Divisions the necessity of having an active charities secretary. To those who are willing to undertake the task of collecting subscriptions for the Royal Medical Benevolent Fund I can promise, from personal experience, the warmest appreciation and thanks from the committee of that Fund.—I am, etc.,

W. G. HARNETT,

Charities Secretary, Barnet Division, B.M.A.
Haddeney, Oct. 23rd.

SIR,—The questions with which Dr. A. J. Hawes opens his letter on this subject may be answered comprehensively in a sentence. It is apparently *not* the desire of the majority of the profession to provide decently for its own

poor. The excellent machinery of the Royal Medical Benevolent Fund is there for the purpose. In many areas there are already local secretaries appointed, who try to practise the suavity and persistence recommended by Dr. Hawes. And with what result? A generous cheque from a minority, some expressed irritation and even downright opposition from a few, and a stony unresponsiveness from the majority.

All that Dr. Hawes desires could be achieved if every medical man with a modest income subscribed a guinea yearly to the Royal Medical Benevolent Fund, well-to-do and wealthy practitioners proportionately higher. The implied reproaches, the begging letters, and the unrelieved distress of our own poor would then all vanish together. Now then, non-subscribers! Why not sit down and write that cheque now?—I am, etc.,

HONORARY LOCAL SECRETARY, R.M.B.F.

Scotland, Oct. 23rd.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on October 19th the degree of Master of Arts was conferred upon the new Professor of Anatomy, Henry Albert Harris, D.Sc., M.D.Lond.

UNIVERSITY OF LONDON

A meeting of the Senate was held on October 24th, with the Vice-Chancellor (Professor L. N. G. Filon) in the chair.

Dr. L. J. Witts was appointed to the chair of medicine, and Professor Geoffrey Hadfield to the chair of pathology, at St. Bartholomew's Hospital Medical College, both from January 1st, 1935.

The following appointments to readerships (indicated in parentheses) at the British Post-Graduate Medical School, from November 1st, were also made: Dr. R. S. Aitken (medicine); Mr. Lambert Rogers (surgery); Dr. J. Chassar Moir (obstetrics and gynaecology); Dr. A. A. Miles (bacteriology); Earl J. King, Ph.D. (pathological chemistry).

Dr. Alexander Haddow was reappointed to the Laura de Saliceto Studentship.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Annual Meeting of Fellows and Members

The annual meeting of Fellows and Members will be held at the College in Lincoln's Inn Fields, W.C., on Thursday, November 15th, at 3 p.m., when a report from the Council will be presented. Fellows and Members can obtain copies of the report on application to the secretary, and can, if they so desire, have their names placed on the list of those to whom the report is sent annually. Motions to be brought forward at the meeting must be signed by the mover, or by the mover and other Fellows and Members, and must be received by the secretary not later than November 5th. A copy of the agenda will thereafter be issued to any Fellow or Member who may apply for one.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A quarterly comitia of the Royal College of Physicians of London was held on October 25th, with the President, Lord Dawson of Penn, in the chair. Dr. J. R. Charles, Dr. C. E. Lakin, and Dr. W. W. C. Topley were elected councillors. Sir Raymond Crawford was elected a representative on the Committee of Management, and Sir Comyns Berkeley a representative of the College on the Central Midwives Board.

The College decided to revise the regulations for the Licence so as to preclude the possibility of foreign medical graduates obtaining the diploma, by an indirect channel, with less than three years' clinical study in this country.

The College approved, by an overwhelming majority, a report from its special committee, which was in general agreement with the recent report of the Departmental Committee on Sterilization.

The President announced the following appointments: Dr. F. Ridehalgh, as Prophit Scholar for the Tuberculosis Survey Scheme; Dr. E. L. Middleton, as Milroy Lecturer for 1936; and William Richard Lambert Harrison, late of Epsom College, as Jenks Scholar for 1934.

Membership

The following candidates, having satisfied the Censors' Board, were admitted Members of the College:

Henry Howarth-Bashford, M.D.Lond., L.R.C.P., Philip Graeme Benthif, M.D.Camb., L.R.C.P., Stanley George Bradfield, M.B. Sydny, Ernest George Brewis, M.D.Durh., Felix Warden Brown, M.B.Oxf., Sushil Chandra Chatterjee, M.B.Calcutta, L.R.C.P., Hugh Richard Jarvis Donald, M.B.Oxf., L.R.C.P., Cyril Percy Donnison, M.D.Lond., L.R.C.P., Clarence Michael Guiney, M.B.Sydny, John Fullford Jarvis, M.B.Lond., L.R.C.P., Bhagwan Singh Khurana, M.B.Punjab, Frank Graham Lescher, M.C., M.D.Camb., L.R.C.P., Harry Stephenson Lecaft, M.D.Ed., Samuel Nevin, M.D.Belf., Carlyle Thornton Potter, M.D.McGill, Lawrence Orred Roberts, M.B.Lond., L.R.C.P., Ibrahim Shawky, Rupert Sykes, M.B.Lond., L.R.C.P., Padukotah Sreenivasachari Varadarajan, M.B.Madras, Herbert John Williams, M.D.Birm., L.R.C.P., Rupert Allan Willis, M.D.Melb., Frederick James Wright, L.R.C.P.

Licences

Licences to practice were conferred upon the following 123 candidates (including eight women) who have passed the final examination in medicine, surgery, and midwifery of the Conjoint Board, and have complied with the necessary by-laws:

A. S. Amsden, N. Angel, T. G. Armstrong, J. C. Baillie, C. R. Barker, G. Batts, D. M. Blomfield, C. H. T. Bond, A. C. E. Breach, D. M. Bressler, Margaret M. B. Carey, R. C. F. Catterall, F. B. Champion, Dora J. A. Clark, J. H. Li. Conway-Hughes, T. Csato, R. H. Dale, S. M. Davidson, D. A. Davies, G. B. Davis, E. W. Dunkley, A. G. Edwards, J. K. Elliott, R. S. Ellis-Brown, E. A. Evans, R. Rouse, B. D. Sachdeva, J. I. Seidman, R. H. Shah, D. B. Shulman, C. W. T. Shuttleworth, J. A. Sidebottom, L. W. Spratt, I. K. Thomas, Nest Thomas, B. Thorne Thorne, T. G. Tregaskis, J. L. Treneman, R. C. H. Tripp, R. J. Vakil, W. Waks, P. A. Walford, H. A. Wallace, F. H. Weston, F. C. H. White, C. T. H. Whiteside, N. Whittaker, S. M. Whitteridge, C. W. K. Willard, E. G. K. Williams, T. M. Williams, W. Wilson, P. L. E. Wood, L. S. F. Woodhead, R. F. Wyatt, Winifred F. Young, R. Clarke, J. R. Dickinson.

Diplomas in Public Health were granted, jointly with the Royal College of Surgeons, to the following:

M. R. Burke, J. O. F. Davies, Joan Goodger, Margaret I. Porteous, K. Rai, A. W. Russell, A. Singh, J. T. Wybourn.

A Diploma in Gynaecology and Obstetrics was granted, jointly with the Royal College of Surgeons, to Hussein Yousri Gohar.

CONJOINT BOARD IN SCOTLAND

The following candidates have been approved at the examinations indicated:

DIPLOMA OF L.R.C.P.ED., L.R.C.S.ED., L.R.F.P. AND S.GLAS.—M. F. Schneekloth, J. L. Jackson, F. Anschacher, M. Gruenbaum, H. Lipschutz, F. Dannheisser, F. M. Abeles, J. Levy, S. L. Last, L. Wislicki, H. Winter, H. Davidsohn, S. James, P. Resenthal, H. Goldschmidt, I. H. B. Ghosh, G. Friedlander, A. B. Sternberg, F. Besser, F. Whyte, O. E. Manasse, K. H. Lepchne, P. L. Rothschild, P. V. J. Solomon, P. A. Printz, C. H. Goldmann, C. H. Straughan, G. Wolff, M. Rakofsky, D. C. L. Stevenson, M. Kraus, A. Ehrlich, W. Cohen, W. Grunstein, H. K. Rosenkranz, R. E. Elkan, J. Puller, Li R. Studebaker, A. B. Morrison, O. S. Kohnstamm, G. Kesak, Erka Schwabacher, T. C. A. Wilson, F. Auerbach, Else F. Meyer, A. Rossmann, R. E. Wilson, H. W. Beetham, W. Buky, F. Muller, M. E. Tausend, R. Friedlander, H. F. D. Whitelaw, T. G. B. Bhagavat, H. Nusbaum, H. Kai-Gee Wong, F. Bernstein, F. Leviv, F. Hussan, Y. Carask
D.P.H.—J. A. Guy, Barbara C. Welsh, J. W. Brydon, H. A. Raeburn, H. Somerville, J. Macfarlane.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—T. D. R. Aubrey, G. A. Bell, W. McC. Graves-Morris, D. W. Houldless, A. Lassman, A. G. Manley.

MEDICINE.—J. W. D. Bull, F. M. Kerry, J. A. McClintock.

FORENSIC MEDICINE.—G. A. Bell, J. A. Carter, W. McC. Graves-Morris, C. C. Joannides, O. C. John, J. C. Pateron, D. Reya-Jones.

MIDWIFERY.—J. H. Bentley, N. Bickford, R. Fleming, C. McK Johnston, H. N. Levitt, A. Ponder, R. C. Sen.

The diploma of the Society has been granted to T. D. R. Aubrey, G. A. Bell, R. Fleming, A. G. Manley, and J. A. McClintock.

Obituary

Sir HAVELOCK CHARLES, Bt., G.C.V.O., LL.D., M.D.

Major-General I.M.S. (ret.)

We regret to announce that Major-General Sir Richard Henry Havelock Charles, Bt., G.C.V.O., K.C.S.I., Bengal Medical Service (retired), died in London on October 27th, aged 76.

He was born on March 10th, 1858, the sixth son of David Hughes Charles, M.D., of Cookstown, County Tyrone, and was educated at Queen's College, Cork, and University College, London, subsequently studying in Paris, Berlin, and Vienna. In 1881 he graduated M.D. with honours and gold medal, and B.Ch. in the Royal University of Ireland. He entered the I.M.S. on April 1st, 1882, passing first into the Service, and at Netley gained the Herbert prize as best man of the year, the Montefiore prize in surgery, and the Parkes gold medal in hygiene. He was, as usual, posted to military duty for the first few years, during which period he served with the Afghan Boundary Commission of 1884-6, afterwards writing a *Report on the Hospital Service of the Commission* in 1886. On his return he was appointed professor of anatomy in the Lahore Medical College; in 1894 he was transferred to the same chair in the Calcutta Medical College, and second surgeon to the Medical College Hospital, and subsequently professor of surgery and first surgeon. He became lieutenant-colonel after twenty years' service, and retired on March 20th, 1908.

In 1906 he was placed on special duty with the Prince and Princess of Wales, now Their Majesties the King and Queen, for their tour in India, and appointed physician-in-ordinary to the Prince of Wales. King George, on his accession to the throne in 1910, appointed him serjeant-surgeon to the King, an ancient post which requires the holder to attend the King when he goes on active service. He held this post till 1928, when he resigned it, and was appointed honorary serjeant-surgeon.

On his retirement Sir Havelock Charles was appointed member of the Medical Board of the India Office from December, 1907; on February 28th, 1913, he became president of the Board, and from June, 1916, also medical adviser to the Secretary of State for India. On becoming president of the Board he was promoted to the rank of major-general. He held these offices up to 1923. He had a long list of honours and titular distinctions. In 1894 he became F.R.C.S.I. In 1906 he received the honorary gold medal from the Royal College of Surgeons of England, and was created K.C.V.O. He received the G.C.V.O. in 1912, a good service pension on October 22nd, 1917, the K.C.S.I. on January 1st, 1923, and a baronetcy on January 2nd, 1923. He also received the LL.D. from Queen's University, Belfast, in 1923. He was dean of the London School of Tropical Medicine in 1916, and president of the Society of Tropical Medicine and Hygiene, and a knight of St. John of Jerusalem. He had been a member of the British Medical Association for thirty-six years. As medical adviser to the Secretary of State for India he attended the Annual Representative Meeting at Cambridge in 1920, during the discussion on naval and military business, and thanked the B.M.A. for what it

had done for all the Medical Services, explaining how conditions of pay, service, and pension of the I.M.S. had been greatly improved, mainly owing to the action taken and the support given by the Association and its Naval and Military Committee.

In 1886 he married Gertrude Seton, daughter of Adam Annand Gordon of Aberdeen; she died in 1923, leaving two sons—Allen Aitchison Havelock, captain Royal Fusiliers, who succeeds to the baronetcy, and Noel Hughes Havelock, M.C., who is in the Diplomatic Service.

DAVID ROGER MOIR, M.A., M.B., Ch.B.

Late Surgeon, Hull and Sculcoates Dispensary

We regret to record the death at Thornccliffe House, Hessle, East Yorks, on October 15th, of Dr. David Roger Moir at the age of 60. Dr. Moir had practised in Hull for the past thirty-four years. He was held in the highest esteem by all his colleagues and patients, and had taken a prominent part in the work of the British Medical Association in East Yorkshire.

Dr. ALEX. URQUHART, Shepperton-on-Thames, writes: As an old friend, fellow student, and fellow graduate of the late Dr. David R. Moir, I wish to pay a tribute to one who was outstanding not only in sound medical knowledge and skill, but also as a man of quiet but impressive influence upon all with whom he came in contact. We entered Aberdeen University together. He was one of the youngest students of his year, only 15, but he was very high up in the bursary competition, showing marked ability in classics, and gaining a special bursary for the excellence of his Latin papers. In all classes he took a good place, and the M.A. degree in 1893. In the same year we entered Marischal College as medical students, and became still closer companions. As students we joined the Volunteer Medical Staff Corps, and there he laid the foundation for his special interest in ambulance work, in which he became later a lecturer and examiner for the St. John Ambulance Association. All through the medical curriculum he was a hard-working and deep-reading student, and in the practical and laboratory work he was very persevering in mastering all details. Owing to the fact that during his student career he did a great amount of teaching and coaching, he did not take honours, but was generally regarded as one of the best graduates when he obtained his M.B., Ch.B. in 1898. After graduation our ways lay apart. He settled in Hull, where he built up a large practice in the course of the years, and was universally respected both on account of his medical skill and as a man of sterling character. He took his full share in the work of the Hull Royal Infirmary, and as a president of the East Yorkshire and North Lincolnshire Branch of the British Medical Association, the Hull Medical Society, and as surgeon to the Hull and Sculcoates Dispensary. In these capacities he was a friend and helper of all classes, and he gave of his best. It was a disappointment to him that he was unable to serve overseas during the war, but he was fully employed at home examining disabled men for the Ministry of Pensions and in many other ways. He was kindly, gentle, and sympathetic to all, a real "David" against the "Goliath" of adversity, and a helper of men and women in times of trouble. Dr. Moir was married, and leaves two daughters and a son, who is a medical student in London.

Dr. JOHN DIVINE writes: In the death of Dr. David Roger Moir, which came as a shock to most of his colleagues, Hull has lost one of a type of men she can

badly spare, and the medical profession one who was an exemplar of its purest ethics: He came to Hull in 1900, well equipped for the work of his life. Settling on Hessle Road, where he practised actively till within ten days of his death, he built up a large practice, and to all of his patients, of whatsoever degree, he gave service the same—his best. He early interested himself in the St. John Ambulance Association and Brigade, and up to the last was an active and valued lecturer and examiner.

At the inception of medical benefit under the Insurance Act in the beginning of 1913 he was elected a member of the Local Medical and Panel Committees, and his sound judgement and knowledge of industrial practice aided these committees along with the Insurance Committee in the smooth working of the Act which distinguished Hull, particularly in the very early days, when points of friction were rife. The dark days and years of the war came. Along with others he offered himself for the Army, but was not accepted for active service. The weary four years were filled by him to the brim with work as physician at the Naval Hospital and as medical examiner of recruits at the City Hall. From the end of 1917 till the end of 1919 he was examiner of disabled men for the Ministry of Pensions, and many wrecks of the war will remember with gratitude their passing through his just but kindly hands. He was a good classical scholar, and well and widely read in English literature. Older members of the Hull Medical Society will recall with pleasure his presidential address on Le Sage's doctors in *Gil Blas*. He was an ex-chairman of the Hull and East Yorkshire Division of the British Medical Association, and ex-president of the East Yorkshire and North Lincolnshire Branch, in each position handling well the helm in the interests of the Association and of the public it has to serve. There has gone a good man and a true.

WALTER GEORGE LOWE, M.D., F.R.C.S.

Consulting Surgeon, Burton-on-Trent Infirmary

We regret to announce the death, on October 21st, of Dr. W. G. Lowe, after a long and distinguished professional career at Burton-on-Trent. He had been a member of the British Medical Association for sixty-two years.

Born in 1848, the son of the late Dr. George Lowe of Burton, he received his medical education at St. Bartholomew's Hospital. He graduated M.B.Lond. in 1870, and in the same year obtained the diplomas M.R.C.S., L.R.C.P. Five years later he advanced to the Fellowship of the Royal College of Surgeons by examination, and in 1876 proceeded M.D. From a house-physicianship at St. Bartholomew's Hospital he returned to Burton, where he practised until his retirement in 1921. He was for many years one of the surgeons at Burton Infirmary, and was subsequently elected consulting surgeon. He became a member of the British Medical Association in August, 1872, was president of the Staffordshire Branch in 1886 and 1909, and was a representative at the Annual Meetings of the Association at Swansea in 1903, Oxford in 1904, Leicester in 1905, and London in 1910. He had also been president of the Midland Medical Society in 1898-9.

Apart from his professional activities, Dr. Lowe took a deep interest in many local concerns. His association with the administration of the Education Act continued for thirty years, for he had been uninterruptedly a member of the local authority—first the old School Board, and later the Borough Education Committee—since 1885. When the present Education Act came into force in 1902 he was co-opted a member of the newly constituted education committee for the borough, and became its vice-chairman in 1912. He was for several years chair-

man of the subcommittee in charge of post-elementary school instruction, and took special interest in the work of evening classes, the School of Science and Art, and the public lectures in the Town Hall. He was also a member of the General Purposes, Juvenile Employment, Elementary Education, and School Attendance Subcommittees, and was for some time a governor of the Burton Endowed Schools. He gave great help to various philanthropic enterprises, and, like his father before him, was a strong and active supporter of Holy Trinity Church.

Dr. Lowe was a surgeon colonel of the old 2nd Volunteer Battalion of the North Staffordshire Regiment, and received the Volunteer Decoration. He was a vice-president of Burton St. John Ambulance Association, and put in much work on its behalf. In Freemasonry he attained Provincial Rank, and he had been Provincial Grand Master of the District in the Manchester Unity of Oddfellows. He was president of numerous sports clubs. When he left Burton he had sat on the borough bench of justices for just over twenty years, and had been a county magistrate for nearly as long. He was buried at Birchington-on-Sea, where he lived after retirement.

Dr. THOMAS NASH THOMAS died at his residence in Solva, Pembrokeshire, on October 22nd, at the age of 74. He had been a member of the British Medical Association for over forty years. He received his medical education at the London Hospital, where he was contemporary with Sir John Lynn-Thomas. After obtaining the M.R.C.S., L.R.C.P., and L.S.A. he settled down in Leicester, where he had a very large practice. So successful was he that at a comparatively young age he was able to retire and to lead the life of a country squire in his native Pembrokeshire. He farmed there on a large scale, but was not allowed to do so for long, inasmuch as his services as a doctor were soon in demand. Dr. Thomas was a master of the art of prescribing. According to the local chemists, his prescriptions were a joy to behold. He deplored the modern habit of tablet prescription. He was a man of wide experience and large sympathies, and his work in Leicester and Pembrokeshire will be long remembered. He leaves a widow, the constant companion and inspiration of his life.

We regret to announce the death, after a long illness, patiently borne, of Dr. SAMUEL JOHN COLE of Bideford, at the age of 78 years. Dr. Cole was a student at the London Hospital, and qualified M.R.C.S., L.R.C.P. in 1887. He was a Fellow of the Royal Institute of Public Health, and had been a prosector of the Royal College of Surgeons; he also occupied the post of school medical officer of the administrative county of West Suffolk. For a short time he was in practice in Pentonville, London. For many years, owing to ill-health, Dr. Cole was obliged to curtail his activities. During the war he did good work in North Devon by filling the vacancies and carrying on the practices of local medical men who were called up for war service.

The death on October 13th, at Fazakerley Sanatorium, Liverpool, after a very brief illness, of Dr. BRERETON GEORGE ELLIOTT, removes a lovable personality from the medical profession. He was the son of the late Rev. John Elliott of Armagh, a brother of Dr. John Trimble Elliott of Smithborough, Co. Monaghan, and a nephew of Colonel C. J. Trimble of Preston. Dr. Elliott had his earlier medical career in private practice in Cherrytree and Witton, Blackburn, where he founded the Blackburn Division of the St. John Ambulance Association. During the Great War he saw active service in two theatres. He had been an officer of the 5th Battalion East Lancashire Volunteers, and on the outbreak of hostilities he accompanied the East Lancashire Territorials, as they had then become, to Egypt. Thence he proceeded with them as a combatant officer to Gallipoli, where he was

promoted to the rank of major. His health becoming impaired on active service he was returned to Egypt to command a military hospital there; subsequently he served at Kimmel Camp. After the war Major Elliott served for a number of years as a resident medical officer at Fazakerley Sanatorium. In these various spheres of activity he quietly won by his kindly disposition, human sympathy, and administrative wisdom, the respect and affection of his soldiers, colleagues, and nursing staffs in hospital, and of the ex-service men, who had always in him a warm friend. Those who knew him well will always remember his quiet drollery and wit.

W. M. K.

The following well-known foreign medical practitioners have recently died. Dr. COURO, professor of clinical medicine and perpetual president of the Academy of Medicine at Rio de Janeiro, foreign associate of the Académie de Médecine of Paris; Dr. MARIO SANATUCCI, professor of the Institute of Hygiene of Rome; and Dr. CECILIA GRIERSON, the first Argentine woman doctor to be qualified (in 1889), who founded the first school for nurses in the Argentine Army and the Argentine Society for First Aid.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Both Houses of Parliament reassembled on October 30th, when the Commons discussed the Incitement to Disaffection Bill. Mr. Ramsay MacDonald promised a day to discuss the reports made by the commissioners dispatched by the Government to the distressed areas.

The Kenya Native.—On October 30th Sir PHILIP CUNLIFF-LISTER informed Dr. O'Donovan that the Governor of Kenya had no doubt that the institution of research on the lines foreshadowed by Dr. H. L. Gordon would assist in the solution of many of the administrative, social, and political problems of the colony, though the state of the colony's finances still made it impossible for the Colonial Government to find the necessary funds. Sir Philip was considering whether there was any means by which the question could be further investigated.

London Refuse.—Sir HILTON YOUNG stated on October 30th that the Advisory Committee on London Refuse had made an interim report dealing with the disposal of house and trade refuse. The Metropolitan Boroughs Standing Joint Committee, of which the committee in question was a subcommittee, has asked for the observations of the Common Council of the City and of the metropolitan borough councils on the report.

Exhaust Fumes in Streets.—Asked to give the result of any recent investigation concerning the effect of exhaust fumes of motor vehicles in crowded thoroughfares, Mr. HORT-BELISHA told the House of Commons on October 30th that he had no information to give beyond that conveyed in a statement of July 30th.

Poor Relief in Scotland.—On September 15th, 162,142 poor persons, with 209,535 dependants, were in receipt of poor relief in Scotland. These include vagrants and persons in receipt of outdoor medical relief.

Imported Foods.—Dr. ELLIOTT announces that exporting foreign countries had agreed to reductions in their quotas for shipments of cream and condensed milk to the United Kingdom. Butter is not included in this arrangement. A measure of co-operation has been secured for regulating meat shipments to the United Kingdom till March 31st.

Slum Clearance.—At September 30th, 60,242 houses in clearance areas in England and Wales were included in clearance or compulsory purchase orders submitted for confirmation or in agreements for purchase. The total number of new dwellings approved for rehousing was 54,524, of which 26,926 had been completed, and a further 19,391 were under construction.

Medico-Legal

BUSINESS RELATIONS BETWEEN DOCTORS*

ASSISTANTS AND LOCUMTENENTS

The doctor who contemplates engaging an assistant or locumtenent will naturally satisfy himself that the newcomer is trustworthy and reasonably competent. He should also, however, pay attention to two important legal implications of the relationship. One is that, as the newcomer is his agent in law, he may in certain circumstances be held responsible for damage caused by the negligence of the assistant or locumtenent. (The extent of his liability was discussed in a former article.¹) The other is that unless the principal and his assistant or deputy make an express agreement to the contrary, there is nothing in law to prevent the latter, on the termination of his contract of service, from practising in the neighbourhood and competing with his former principal.

The only practical way in which a practitioner can avert the great expense and harm that may result if an aggrieved patient brings an action for negligence is to require any registered assistant he employs to be a member of a defence society. He is covered by his own society against claims arising out of the acts of his locumtenent but not those of his assistant, and he will be seriously inconvenienced if his assistant gets into legal difficulties. The intervention of a defence society is, moreover, sufficient in the vast majority of cases to discourage a potential litigant from proceeding any further. He may protect himself—though not his assistant—against claims arising out of the work of his assistant by paying a small extra subscription. The two largest defence societies have a reciprocal agreement by which each will defend a member in an action arising out of the act or omission of an assistant or locumtenent who is a member of the other society. The subject of restrictive covenants has already been dealt with.²

It follows that a practitioner who employs an assistant or a locumtenent without entering into a written agreement is taking a great and quite unnecessary risk. Moreover, the contract—like all agreements between medical men—should be drawn up by a solicitor with experience of the legal pitfalls of medical practice. Barnard and Stocker give a useful form,³ and the British Medical Association⁴ suggests that the agreement should contain the following conditions:

1. The assistant to give diligent and faithful service.
2. The assistant to give his whole time and attention to the practice under the direction of the principal.
3. The assistant to receive from the principal periodic payment for his services, at an agreed rate.
4. The assistant to keep just accounts and pay over to the principal all moneys received on behalf of the practice.
5. Provision for a holiday for the assistant.
6. Provision for the determination of the agreement.
7. Period for the duration of the agreement.
8. A restrictive clause as to practice by the assistant during and after termination of the agreement.
9. A provision that both the principal and the assistant should be members of one of the medical defence societies during the whole period covered by the agreement, and also one for the settlement of disputes by arbitration.
10. That if the assistant's name is placed upon the medical list of the National Health Insurance Committee the assistant must agree that either the assistant shall not accept any insured person other than in the name of and on behalf of the principal, or if any insured persons are accepted in the name of the assistant he shall take every possible means to ensure the transfer of those persons to the list of the principal on the termination of the agreement.

* The first of these articles, by a legal correspondent, appeared on June 9th, 1934 (p. 1053), the second on June 23rd (p. 1145), the third on July 7th (p. 42), the fourth on July 21st (p. 141), the fifth on September 22nd (p. 574), the sixth on October 6th (p. 660), and the seventh on October 20th (p. 730).

¹ British Medical Journal, 1933, i, 1029.

² Ibid., October 20th, 1934, p. 750.

³ Medical Partnerships, Transfers, and Assistantships, 1913, p. 59.

⁴ Handbook for Recently Qualified Medical Practitioners, British Medical Association. (38, 61.)

One authority advises the principal to demand from the assistant at the beginning of his service a signed form requesting the transfer to the name of the principal of all patients who have been accepted by the assistant in his own name. He can, if necessary, make use of this form when the contract of service expires.

ASSISTANT WITH A VIEW TO PARTNERSHIP

When a young man looking for a practice meets an older man who is not quite certain whether or not he wants to sell a part of his interest, the suggestion often arises that the younger shall act as assistant to the older with a view to becoming a partner later on. The British Medical Association recommends a young practitioner to become an assistant with a view to partnership, regarding this as a good and practical way of making himself familiar with the work of the practice. Moreover, it gives the older man an opportunity of assuring himself that the young man will make the kind of partner he wants. The arrangement seems, on the face of it, a good one, but Barnard and Stocker do not recommend it. These authors say that, as a matter of experience, only about one assistant in every twelve who begin with partnership in view ever becomes a partner. If, they suggest, the principal really wants the assistant as a partner, and the assistant really wants and can afford to become a partner, and they agree on the terms of the partnership articles before they start work together, there is no fault to be found with the arrangement. Unfortunately, one of its chief attractions is that it gives both parties an excellent pretext for shelving the difficult and delicate task of settling terms of partnership. The fulfilment of the project is occasionally, they say, prevented by some unforeseen circumstance, but more usually because one of the parties becomes conscious of an objection about which he could equally well have made up his mind at the outset. The disadvantages to the principal of an abortive attempt of this kind are that the practice suffers a decrease in value; to the assistant they are that to work for a considerable time, to find everything satisfactory, and then to be refused a partnership after all is annoying and may be discouraging.

Doctors contemplating this relationship must therefore form their own opinion on whether the risk is one which they care to take. Where the parties are practically certain that they want to enter into partnership together, they may find it useful to make an agreement to do so on a certain date, with a stipulation that if either refuses to do so without good and sufficient cause he will pay to the other a named sum as damages. The following point is serious enough to deserve memorizing. If an assistant is wrongfully dismissed the courts will probably hold that, as the employer has broken an important term of the contract, the whole contract is at an end. The natural consequence is that the restrictive covenant no longer binds the assistant (General Bill Posting Company v. Atkinson, 1908) and he is free to come and set up in practice as near his ex-principal as he likes. A doctor who wishes to dismiss his assistant should therefore be very careful not to run the risk of breaking his contract in doing so. It may, in fact, be well worth his while to seek legal advice before he takes any drastic step. A competitor who combines a strong personal grievance with an intimate knowledge of the practice is able to be a disturbing factor in any doctor's environment.

Under the Workmen's Compensation Acts an employer is bound in certain circumstances to compensate a "workman" for personal injury, and "workman" includes anyone who has made a contract of service. A doctor employing an assistant or locumtenent at a salary should therefore remember to insure himself against the risk of having to pay compensation under these Acts. If, however, the assistant or locumtenent is receiving more than £350 a year, he is not a "workman."

An assistant who is remunerated by receiving a share of the profits has a right to overhaul his employer's accounts and books, although he has none of the other rights of a partner. A practitioner may enter into an agreement with the widow of a deceased practitioner to carry on the practice for her for a salary, she to be

financially responsible for the practice and to take the profits. If, however, she interferes with the conduct of the practice or practises herself, the General Medical Council may consider him to be guilty of the offence of "covering," an unqualified person and remove his name from the *Register*. Such arrangements, according to one large defence society, do not usually work well for very long.

A locumtenent² is the confidential agent of his employer and is bound in law, as well as in honour, to try to serve the interests of his practitioner and to maintain a good relationship with patients and the other doctors of the neighbourhood as assiduously as though he himself were the owner of the practice. He may make no profits of any kind from the work other than that which he has agreed to accept from his principal, and if he retains for himself any money given him in return for professional services, he is not only liable to pay his principal damages to the value of this unlawful profit, and the costs of the action, but may also be prosecuted under the Prevention of Corruption Act, 1906, which lays down that an agent, on pain of fine or imprisonment, may not accept for himself any profit without the knowledge of his principal. It is grossly unethical for a locumtenent to set up in practice in a place to which he has first come in that capacity, but it is only a legal wrong if he has signed a covenant binding him not to do so.

Medical News

On Tuesday, November 6th, Professor F. A. E. Crew of Edinburgh will deliver the Lloyd Roberts Lecture, on "Medicine and the Further Evolution of Society," at the Manchester Royal Infirmary.

The annual general meeting of the West Riding Association of Graduates of the University of Edinburgh will be held at the Great Northern Hotel, Leeds, on Wednesday, November 14th, at 6.45 p.m. The annual dinner will follow at 7.30. The guest of the evening will be Mr. John Wheeler Dowden. Graduates please take note of this date. Applications for further information to the honorary secretary, 33, Manor Row, Bradford.

The Glasgow University Club, London, will dine at the Café Royal, Regent Street, W., on Friday, November 23rd, at 7.30 p.m., with Professor Alexander Macphail in the chair. Any Glasgow University men who, though not members of the club, desire to attend are asked to communicate with the honorary secretaries, 62, Harley House, N.W.1.

A public lecture under the Chadwick Trust, on "Fifty Years of Public Health Progress," will be given by Dr. Matthew B. Ray at Huddersfield Technical College on Friday, November 9th, at 7.30 p.m.

A lecture on the theory and practice of contraception will be given to medical practitioners and students who have completed their gynaecological course by Dr. Gladys Cox on November 16th, at 6 p.m., at the Walworth Women's Welfare Centre, 153A, East Street, S.E.17. Demonstrations will be given on November 23rd and 30th at 6 p.m. and 7 p.m. (those attending are asked to bring rubber gloves). To cover expenses of lecture and demonstration a fee of 5s. is charged. Tickets admitting to the lecture are to be applied for in advance.

The 1934-5 session of the West Kent Medico-Chirurgical Society opened on October 12th at the Miller General Hospital with the annual general meeting. The following lectures have been arranged: November 9th, Mr. G. John Sophian, "Physiology and Pathology of Menstruation"; December 14th, Sir Humphry Rolleston, "Shifting Sands of the Architecture of Medicine"; February 8th, 1935, Dr. H. Stanley Banks, "Serum Treatment of Scarlet Fever, Diphtheria, and Measles"; March 5th, Mr. A. Lawrence Abel, "Common Diseases of the Rectum and Anal Canal." On April 12th there will be a debate on

"That Surgery is the Method of Election for the Treatment of Peptic Ulcers." For the motion, Mr. C. A. Joll, seconded by Dr. H. V. Morlock; against, Dr. Harold Pritchard, seconded by Mr. R. C. B. Ledlie.

The following lecture-demonstrations have been arranged by the South-West London Post-Graduate Association at St. James's Hospital, Ouseley Road, S.W., on Wednesday at 4 p.m.: November 7th, Dr. W. G. Wyllie, "Pulmonary Fibrosis and Bronchiectasis in Children"; November 14th, Dr. Stanley Wyard, "Tuberculosis in Children"; November 21st, Dr. C. E. Lakin, demonstration of medical cases; November 28th, Dr. Braxton Hicks, "Some Mutual Difficulties of the Clinician and the Pathologist"; December 5th, Mr. V. Z. Cope, demonstration of surgical cases; December 12th, Mr. L. Phillips, "Some Medical Aspects of Gynaecology."

A course of three lectures on "Newer Aspects of Gastritis and its Consequences" will be given by Dr. Knud Faber, professor of medicine in the University of Copenhagen, at Guy's Hospital Medical School, London Bridge, S.E., on November 6th, 8th, and 9th, at 5 p.m. Dr. Arthur Hurst will take the chair at the first lecture. Admission free, without ticket.

The 1934-5 session of the North London Medical and Chirurgical Society opened on October 10th, when Dr. H. Letheby Tidy gave an address on some modern views on anaemia. The programme includes clinical demonstrations on November 15th, 1934, and February 14th, 1935, and the following addresses: December 14th, Dr. Rubens Wade, "Some Aspects of Anaesthesia"; January 16th, 1935, Sir William Wilcoxon, "Common Functional Disorders of the Liver"; March 13th, Mr. Eric Lloyd, "Scoliosis."

The Cancer Hospital (Free), Fulham Road, S.W., announces that a series of lectures on cancer will be given in the lecture theatre of the hospital on Thursdays at 4 p.m. from January 3rd to April 11th, 1935, inclusive. No charge is made for attendance at the course, which is open only to medical practitioners.

A discussion on the bed-bug as a housing problem will be introduced by Mr. A. W. McKenny Hughes at a meeting of the Royal Sanitary Institute at 90, Buckingham Palace Road, S.W., on Tuesday, November 13th, at 5.15 p.m., when Lord Balfour of Burleigh will preside. The opening paper will deal with the disinfection of houses and furniture, and the prevention of infestation.

At the official opening ceremony of the West Lane Hospital Nurses' Home, Middlesbrough, on October 30th, the mayor said that the past year had been memorable, especially in regard to hospital and public health services generally, both at the Holgate Municipal Hospital and at the Poole Sanatorium, as well as at the hospital in West Lane. He paid a warm tribute to Dr. C. V. Dingle, the medical officer of health, who had worked for several years towards the fulfilment of a scheme to provide these necessary extensions.

The Fellowship of Medicine (1, Wimpole Street, W.) announces that lecture-demonstrations will be given at 11, Chandos Street, W., on November 6th and 13th at 2.30 p.m. In the series of lectures on diet and dietetics, on Wednesdays at 8.30 p.m., at 11, Chandos Street, W., Dr. E. G. B. Calvert will speak on diet of the diabetic, on November 7th, and Dr. F. W. Christie on diet of the obese and thin, on November 14th. On November 10th, at 3 p.m., there will be a special demonstration of surgical cases by Mr. C. E. Shattock, at the National Temperance Hospital, Hampstead Road, N.W. Forthcoming courses of instruction include venereal disease at the London Lock Hospital, November 12th to December 8th; gynaecology at the Samaritan Hospital, November 17th and 18th; proctology at St. Mark's Hospital, November 19th to 24th; and an evening course in rheumatism at the British Red Cross Clinic on Tuesdays and Thursdays from November 20th to December 6th. A special M.R.C.P. course in diseases of the chest will be given at the Brompton Hospital between December 17th and January 11th. A panel of teachers is available daily for individual tuition in various branches of medicine and surgery.

² B.M.A. Handbook for the Newly Qualified, 1923, p. 11.

The first Rumanian Congress of Medical Radiology and Electrolgy will be held at Bucarest from November 8th to 10th under the presidency of Dr. Severeanu. The subjects for discussion will be cholecystography, x-ray diagnosis of intrathoracic tuberculosis, radiotherapy of mammary cancer, and actinotherapy of erysipelas. The general secretary is Dr. G. N. Giurea, Str. Stirber Voda 108, Bucarest.

The council of the University of Manchester has equipped a laboratory of surgical research at 20, York Place, immediately adjacent to the Royal Infirmary. Applications to work in the laboratory should be made in the first instance to Professor E. D. Telford.

The High Commissioner for India has been asked by the Indian Research Fund Association to invite applications for the post of Director of Nutritional Research at Coonoor, in the Madras Presidency. Candidates must be graduates in medicine with a wide experience of nutritional research, both in the field and in the laboratory, who have made original contributions on the subject. They must be of sound constitution, and not more than 45 years of age. A notice giving further particulars appeared in the advertisement columns of the *British Medical Journal* of October 13th (p. 50). Applications must be made on the prescribed form, copies of which can be had from the High Commissioner, India House, Aldwych, W.C.2. Completed forms must be received by November 30th.

Professor Sudhoff of Leipzig, who recently celebrated his eighty-first birthday, has resumed the editorship of the journal which is henceforward to be known as *Sudhoffs Archiv für Geschichte der Medizin und der Naturwissenschaften*, in collaboration with Professor Dr. J. D. Achelis.

A square in front of the Salpêtrière, Paris, has recently been named after the late Mme Marie Curie.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and **LETTERS** forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBER** of the British Medical Association and the *British Medical Journal* is **EUSTON 2111** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Atiology
Westcott, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER
(Advertisements, etc.), *Articulate Westcott, London.*

MEDICAL SECRETARY, Medicis Westcott, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62589 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Aerophagy with Meteorism

"PERPLEXED" asks for suggestions regarding a case of aerophagy in a man, aged 40, with ensuing meteorism. The condition is always worse when the patient is excited or nervous, and occasionally occurs after a long railway journey. There is marked distension of the abdomen, and intense discomfort. After a couple of hours or so the air becomes gradually expelled, per rectum. Nothing organic can be discovered.

Treatment of Ménière's Disease

"INQUIRER" writes from Northern Ireland: Could any of your readers suggest treatment for a case of Ménière's disease? The patient is a man of about 50, and has been suffering from this complaint for from three to four years. Bromides and luminal appear to have little, if any, effect on the onset of attacks.

** An annotation on this subject was published in the *Journal* of October 27th (p. 779).

Trichophyton Infection

Dr. J. F. BRISCOE (London S.W.1) writes: Tinea tonsurans in the Victorian age was a most common malady of children's heads, and if not treated promptly became an intractable complaint. The fungus in chronic cases, growing deeply, resisted ordinary medicaments. At one of our large public schools glacial acetic acid was introduced as an ideal remedy, and the acid was well rubbed in, perhaps once, or maybe twice. If it was a small patch the drug proved effective. At that period, too, short of blistering, many cases gave prolonged trouble. To-day, disease is caught so early that ringworm can be readily dispatched, since children's heads are now "drilled" at and after school hours. Moreover, in my opinion, singeing the scalp may interrupt the growing spores and the filamentary mycelium threads, and I am positive it stays baldness. Dhobi itch, and all the contagious tinea, may be treated successfully in the same routine method as tinea tonsurans. With the acetic acid, white precipitate ointment, even an application of liquor potassae, and hyposulphite of soda in tinea versicolor are remedies out of fashion which are not to be despised. Changing linen and woollen vests, and especially the pants, needs careful attention; while trousers long worn are like the old women's petticoats, needing the sterilizing chamber. To be certain of success the secret of the treatment of all the fungoid eruptions of the skin is to get your application below the epidermis.

Income Tax

Payment of Annuity

"J. B." writes: About three months ago I wrote to you about a claim for repayment of income tax by a relative to whom I pay an annuity. I would like to let you know that I followed the advice you were good enough to give me in the *British Medical Journal* for July 14th (p. 98). A reply has just come from Somerset House to the effect that they agree with the inspector that, having regard to the form of the agreement, the annuitant was not entitled to the repayments in question, but they do not think that in the circumstances they can claim a refund of the amounts overpaid. "No further application for a refund will therefore be made." May I offer my sincere thanks for your help in the matter.

Motor Car Replacement

"E. B." has had the following car transactions in 1933-4: On April 1st, 1933, he owned a 12-h.p. "A" car, written down value £41; on April 25th he sold it for £70 and bought an 18-h.p. "T" car for £295; in June he sold the "T" car for £225 and bought an "S" (new) car for £235; in November he sold that car for £90 and bought an "A" car for £30. He has been allowed £40 for the loss on the "T" car and £30 for the loss on the "S" car.

* The latter item (£30) is, of course, much less than the loss incurred on the "S" car, which was £235 - £90 = £145. The difficulty is that the allowance is not specifically for the loss on the car replaced, but is for the expenditure on the new car—to the extent of the loss incurred on the old one. As £30 only was spent on the purchase of the last car, that limits the allowance in respect of the replacement of the new "S" car to that sum.

"W. H." runs two cars; one is an 8.3-h.p. "R" car, bought second hand for £55, and he intends to sell it for, say, £15, and buy a new 9.8-h.p. "H" car for £179. What is his best course as regards income tax allowances?

* He can claim a replacement allowance of (£35 - £15 =) £20 as an expense of the year 1934. That, however, will preclude him from claiming the depreciation allowance of (£179 at 22 per cent. =) £39 for 1935-6. He can, however, claim that allowance—that is (£140 at 22 per cent. =) £31, for 1936-7, and so on for future years. When the "H" car is replaced he should claim obsolescence allowance—that is, £179 less the amount received on sale.

and less the aggregate depreciation allowances, but *excluding the non-effective allowance for 1935-6*. He will then have received the full amount due in law and in equity.

Private Motoring Expenses

"J. F. M." has in the past been allowed running expenses and wear and tear in respect of his car; the inspector of taxes suggests that one-tenth of each kind of deduction should be treated as applicable to private use. Should the wear and tear allowance be added to the expenses claimed, which cover the whole cost of running, etc.?

*. Whether one-tenth is reasonable or excessive depends on the extent of private use of the car, and varies so much that no rule of thumb is of much use as a guide. If that is a fair ratio it does apply to the wear and tear allowance as well as to the out-of-pocket expenses. That allowance is correctly treated as an addition because it is in anticipation (wholly or in part) of the cost of replacement.

Expenses of an Attack of Scarlet Fever

"E. M." contracted scarlet fever in the course of discharging his professional duties; are the resulting expenses allowable?

*. We fear not, though the point is not beyond doubt. The statute forbids the deduction of sums "not being money wholly and exclusively laid out or expended for the purposes of the . . . profession." In such a case as this it is arguable that the expenses are incurred because the practitioner cannot exercise his profession, and the word "exclusively" is awkward to get round in this connexion. The Board of Inland Revenue allows the cost of the services of a locumtenent, but that is as far as it is apparently willing to go. The deduction is worth claiming, but we could not advise "E. M." to carry his point to appeal.

Purchase of Practice

"G. H." purchased a practice in May, 1934; prior to that he was employed as an assistant elsewhere. He has had a notice of assessment for 1934-5, apparently based on the estimated profit of the practice.

*. He is chargeable to tax (a) under Schedule D, on the current year's earnings; (b) under Schedule E, on the previous year's basis for the proportion of the year to the date when his employment ceased. Thus suppose it ceased and he took over the practice as at May 5th, 1934, then he is liable (a) on the earnings for the eleven months to April 5th, 1935, and (b) on 1/12 of his employment earnings for the year to April 5th, 1934.

Surgery, etc., at Private Residence

"W. H. H." pays rent and rates amounting to £110 + £31 = £141, and hitherto has been allowed one-half of that expense as applicable to professional purposes. The local inspector of taxes now claims to restrict it to two-fifths—that is, £57—and "W. H. H." is considering the question of an appeal.

*. It is difficult in this sort of case to give definite advice, as so much depends on the exact circumstances—for example, the amount of rent which covers the garage, whether the "professional" maid has a separate room, etc. One useful criterion is whether the three-fifths borne privately is reasonable—for example, would the practitioner obtain similar private accommodation for £84 rent and rates to that which he enjoys now? A formal appeal is probably not worth while, but a personal discussion of the details with the inspector might be useful.

LETTERS, NOTES, ETC.

Infantile Eczema

Dr. R. CHALMERS (Darlington) writes: In a review in the *Journal* of October 13th (p. 680) you quote the findings of Dr. Péhu and Dr. Aulagnier, both of Lyons, as to the aetiology of the condition referred to above—namely, an allergic condition due to an enterococcus, which these workers treat with a vaccine. An experience I had in June, 1932, may be of interest in this connexion. A baby, about 9 months old, was brought to me covered with eczema from head to foot. The history was that it had

been quite well until it went to the seaside a week or so before. No change had been made in feeding. The urine was alkaline, and showed organisms + +. I put the child on to mist, acid, sodii phos, cum hexamine, with tab. parathyroid (1/20 grain) daily, calamine lotion to the skin, and only olive oil to be used in place of soap and water for cleansing. In one week the whole condition had entirely cleared up.

An Irish Medical MS.

Dr. WINIFRED WULF (Templeogue, Co. Dublin) writes: I should like to thank you for the kind notice of my book, *A Handbook of Gynaecology and Midwifery* (Irish Texts), which appeared in your issue of September 22nd (p. 555). There is one point I should like to make clear. Your reviewer does not appear to realize that the Irish version of *Trotula* and John of Gaddesden is a faithful translation—indeed, a literal translation, except in a few minor details—of the Latin as it appears in the printed edition, and which is here printed side by side with the Irish. Since the Irish translation was made, as your reviewer correctly states, some two hundred years before the Latin edition was published, it is interesting to note how closely the translator has kept to the original Latin manuscript. As the book is intended for scholars it was not considered necessary to translate either the Latin or the Irish into English.

Eustace Smith's Sign

Though in itself of little practical value, the above sign is a good example of a single eponym striving to capture the personality of a man who has left his mark on a multitude of scientific problems. It was first described in a short paper entitled "On the Diagnosis of Enlarged Bronchial Glands in Children" in the *Lancet* (1875, ii, 240), and consists in a venous hum heard over the upper part of the sternum when the child bends back its head. The original description is quoted by Dr. W. R. Bett in the current issue of the *British Journal of Children's Diseases* (July-September). Eustace Smith was one of the first physicians in this country to specialize in children's diseases, and for forty-three years he was associated with the East London Hospital for Children, Shadwell. He was a fine clinician and a skilled percussor, whose deft touch remained unimpaired till the very end. A faithful believer in drugs, he was fond of big doses. His emphasis in a doubtful case of whooping-cough on the disproportion between the violence of the cough and the signs in the chest is still regarded as a useful aid to diagnosis. The culminating point in his career was his election to the presidency of the Children's Section at the International Congress in 1913.

Corrigenda

In the footnote to our review of Harrow and Sherwin's *Chemistry of the Hormones* (October 27th, p. 773) the price of the book was given as 1s. 6d. This should have been 11s. 6d.

Dr. A. J. HAWES wishes to correct a slip in his article on the death of Mauriceau's sister published last week (p. 782). The title of the book referred to is *De la Perte de Sang*.

Boots Pure Drug Co. Ltd., Nottingham, have issued a well-illustrated booklet on "bismostab," their 20 per cent. suspension of bismuth (B.P.) in isotonic glucose solution, for injection in cases of spirochaetal diseases. A feature is the complete course outlined for the routine treatment of adult syphilis with this preparation by the "concurrent" and "alternate" methods. A copy will be sent free of charge to medical men who apply.

The Medical Supply Association Limited (Gray's Inn Road, and 95, Wimpole Street) have issued two new booklets, one on electrotherapy apparatus and the other on the "medisun" lamp ultra-violet ray generator. Copies will be sent on request to any medical practitioner or accredited assistant.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 55, 56, 57, 58, 59, 62, 63, and 64 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 60 and 61. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 236.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, NOVEMBER 10th, 1934

TOXIC GOITRE: A SURVEY OF 125 CASES TREATED SURGICALLY

BY

JAMES M. GRAHAM, CH.M., F.R.C.S.ED.

SURGEON, ROYAL INFIRMARY, EDINBURGH

AND

H. L. WALLACE, M.B., F.R.C.P.ED.

ASSISTANT PHYSICIAN, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN, AND LEITH GENERAL HOSPITAL

(From the Statistical Research Department of the Royal Infirmary, Edinburgh)

This paper is based on an analysis of 125 consecutive and unselected cases of toxic goitre treated by operation. All the cases came under the charge of one surgeon during a period of sixteen years. A few of the cases were treated as far back as 1918, but the majority have been operated on during the last six years. It is not our intention to present in any detail the symptomatology of toxic goitre or the operative technique, but rather to record the results of operative treatment in a representative series of consecutive cases. We are fortunate in that the great majority of the patients have been able to report periodically at hospital, so that it has been possible to make regular observations of their progress. All but a few were treated in the wards of the Royal Infirmary; cases treated privately have also been included to enlarge the series.

To simplify description cases have been divided into two groups—primary and secondary toxic goitre. Primary toxic goitre signifies toxic symptoms occurring as a result of pathological changes in a previously normal thyroid, giving rise in the majority of cases to typical exophthalmic goitre. The group classed as secondary toxic goitre includes those cases in which some simple form of goitre preceded the development of toxic symptoms, and the cases in this group correspond closely to those formerly described by Plummer as toxic adenoma. This classification, though it may be open to objection, is simple and comprehensive.

In our series of 125 cases 105 were classified as primary toxic goitre and twenty as secondary toxic goitre. On account of the difficulty of allocating some cases, these figures should be regarded as being only approximately accurate.

Sex and Age Incidence

Of the 125 cases 109 were females and sixteen were males: a sex ratio of 6.8 to 1. The largest number of cases occurred at the age period 20 to 40, the average age for the whole series being 33 years. Seven patients were under 20 and sixteen were over 50 years of age.

Duration

The duration of symptoms prior to operation varied from a few months to eighteen years, with an average of thirty-two months. In our experience it is not infrequently difficult to estimate the exact duration of symptoms, since patients with toxic goitre are apt to be

vague in their statements and tend to underestimate the duration of their illness.

Severity of Cases

Since the severity of toxic symptoms may have an important bearing on the results of treatment, we have graded our cases as severe, moderate, and mild. In the severe group are included patients who at the time of operation were extremely toxic, bed-ridden, and entirely incapable of even the lightest activity. The moderate group comprises patients who showed very definite toxic symptoms and were unfit for their employment, but who managed with difficulty to "remain on their feet" and perhaps carry out the easiest household duties. In the group classed as mild are patients who showed only comparatively slight toxic symptoms and who were able to perform their various duties, although with some considerable effort.

In the following table the number of cases allotted to each group is shown:

Severe	33, or 26.4 per cent.
Moderate	65, or 52.0 " "
Mild	20, or 16.0 " "
Not classified	7, or 5.6 " "

Previous Medical Treatment

A considerable proportion of the cases in this series had undergone a systematic trial of medical treatment before they were finally submitted to operation. Out of the total of 125, eighty-two had received prolonged courses of treatment in the medical wards apart from the usual pre-operative preparation. Such treatment consisted in long periods of rest in bed with iodine medication, and in some cases irradiation with radium had been tried. In the remaining forty-three cases, although we have no record of any intensive medical treatment prior to operation, we have reason to believe that the majority were treated with iodine and rest in their own homes.

Operation

Pre-operative Treatment.—Apart from the earlier cases in this series iodine has been given pre-operatively in the form either of Lugol's solution in doses of from 5 to 15 minims daily or of potassium iodide, 2 to 4 grains daily, over a period of from ten days to three weeks. When the symptoms have been severe larger doses of iodine have been found necessary. This regime has been

employed in both primary and secondary cases. Operation was performed when the maximum benefit seemed to have occurred, usually within ten to twenty-one days. The striking benefit which usually follows the administration of iodine is not as a rule maintained; it is therefore an advantage if the iodine is discontinued for some time before the patient is admitted for preparation for operation. The diet given in the average case has a caloric value of between 2,800 and 3,000. No effort is made to force diets of 5,000 calories as such forced feeding tends to disturb digestion. The patient is encouraged to take glucose drinks during the pre-operative period and, during the two days immediately preceding operation, receives 100 grams of glucose daily.

Anaesthesia.—In the earlier cases in this series either open or intratracheal ether anaesthesia was employed; later, gas and oxygen were preferred when a general anaesthetic was indicated. Local anaesthesia has, however, been employed in the majority of cases, and during the last six years has been regarded as the method of choice. Anaesthesia is induced by local infiltration of the operation area with 1 per cent. novocain solution and by regional block of the branches of the cervical plexus at the posterior border of the sternomastoid muscles. Care is taken to introduce the solution around the upper poles and above the isthmus of the gland. Local anaesthesia alone has been used successfully in ninety-seven of the cases in this series, and in only nine of these was it necessary to supplement it with light general anaesthesia. General anaesthesia alone has been used in twenty-eight cases. It is an advantage of local anaesthesia that the operation must be done with gentleness, and with the minimum of trauma, and that the patient can phonate at any stage of the operation if the integrity of the recurrent nerves requires to be decided. After operation under local anaesthesia the patient can take fluids at once, and there is a lessened tendency to respiratory complications. In order to perform the operation satisfactorily a pre-operative sedative is advisable. On the night before operation the patient receives 6 grains of veronal and 5 grains of aspirin. One and a half hours before operation one-third of a grain of omnopon is given, and one hour later, depending on the patient's reaction to the first dose, a second injection of omnopon is given if necessary. With omnopon as a pre-operative sedative the patient remains conscious and lies quietly during the operation. We have not observed any diminution of the respiratory rate in any of the cases in which omnopon has been used such as occurs with morphine and heroin. The use of omnopon has helped to strengthen our faith in the advantages of local anaesthesia in all types of toxic goitre, including those cases which at best can only be regarded as bad subjects for operation. Earlier experience with morphine and hyoscine was not uniformly satisfactory, as in some cases the hyoscine excited rather than quieted the patient. In a few cases avertin was used, but with it it was found impossible to perform the operation under local anaesthesia. The combination of avertin and light general anaesthesia, however, gave satisfactory results in the cases in which it was employed.

Operative Technique.—In the following tables are shown the types of operation performed in this series.

(A) Primary Toxic Goitre

	Cases
(1) Subtotal thyroidectomy	97
(a) One-stage operation	93
(b) Preliminary ligation of superior thyroid arteries with subsequent subtotal thyroidectomy	2
(c) Subtotal thyroidectomy in two stages	2
(2) Resection of one lobe	7
(3) Ligation of superior thyroid arteries	1
Total ...	105

(B) Secondary Toxic Goitre

	Cases
(1) Bilateral resection	10
(2) Enucleation of adenoma	7
(3) Resection of one lobe	3
Total ...	20

It will be noted from the above tables that one-stage bilateral subtotal thyroidectomy was performed in a very high proportion of the cases. The following is a brief outline of the technique employed in this operation:

After reflection of the skin and platysma, exposure is facilitated by wide separation of the skin flaps with a self-retaining retractor. The depressor muscles are freely separated in the mid-line. Transverse division of the muscles is seldom necessary. At the outset the upper pole of the right lobe is exposed and the superior thyroid vessels are ligated and divided. The lobe is drawn medially, and the middle thyroid vein and other accessory veins are secured at the lateral aspect of the lobe. The lower pole is finally drawn forwards, and after the thyroid sheath has been separated the inferior thyroid veins are ligated and divided, and the trachea is exposed. The left lobe is dealt with in a similar manner. After the whole gland has been freely exposed the isthmus is divided between clamps and each half is dissected laterally until the anterior part of the lateral surface of the trachea is exposed on either side. The greater part of each lobe is removed by sharp dissection with the knife from the medial to the lateral side, leaving a strip of the postero-medial part of each lobe with its capsule intact. The margins of the thyroid remnant are sutured together with catgut. In very toxic cases the amount of thyroid tissue left on each side is approximately equal in size to one-third of a normal lobe. When involution is well marked more tissue is conserved. In our experience there is a tendency to remove too little rather than too much gland tissue. A small glass drainage tube is inserted through a puncture in the pre-thyroid muscles on each side into the lowest part of the space around the trachea. The drains are brought out laterally between the lips of the wound, the edges of which, including the platysma, are approximated by fine catgut sutures and Michel clips.

Post-operative Treatment.—After operation the patient is encouraged to take fluids freely by the mouth. Six ounces of glucose-saline are given per rectum four-hourly during the first two days, a total of 50 to 100 grams of glucose being given during the first twenty-four hours. While the patient remains in the surgical ward the same dose of iodine is given as was taken before the operation, and thereafter the iodine is discontinued unless the pulse rate remains high. The drains are removed in twenty-four to forty-eight hours, and the clips on the third day, when the edges of the wound are painted with collodion to maintain apposition. After leaving the surgical ward the patient is usually transferred to a medical ward or convalescent home for a further period of rest. Patients who return direct to their homes are advised to continue to rest in bed for a few weeks, and to resume normal activities very gradually.

Post-operative Complications

Shock.—Although shock is exceptional, the blood pressure may be reduced as a result of the operation, particularly in chronic cases in which the gland has been unusually vascular and friable. In these circumstances we have given a transfusion of blood at the conclusion of the operation, which has had the immediate effect of restoring the patient to a safe condition.

Sepsis.—No serious infection occurred in the series. In six cases a mild infection developed; these were all cases in which there was a collection of serum which necessitated the reinsertion of a drain. In none of the cases was complete healing delayed for more than a few days. In these cases with mild infection the average

number of days in the ward was 19, as compared with twelve days for the whole series.

Conjunctivitis.—This complication is liable to occur in cases with severe exophthalmos in which the eyelids fail to close during sleep or when the patient is under the influence of a sedative. Slight conjunctivitis occurred in a few of the early cases of this series. Subsequent experience has shown that it can readily be prevented by using some suitable eyewash and by protecting the eyes at night with a vaseline dressing kept in position by means of a bandage.

Dyspnoea from Pressure of Blood Clot.—In two cases the patient, who was perfectly comfortable and in good condition after returning to bed, developed after a few hours rapidly increasing dyspnoea with stridor. The rapidity with which the dyspnoea developed was such that both patients were soon in a critical condition. The stridor, which could be heard outside the ward, suggested bilateral abductor paralysis of the vocal cords. Within a few minutes of the onset of the dyspnoea in both cases the wound was opened up, and some clots under tension were evacuated from the retrosternal space. No bleeding points were seen, and there was no evidence of compression or collapse of the trachea. Within a few minutes the breathing became quieter, and within an hour it was normal. On examination of the larynx on the following day the vocal cords in both cases were found to move perfectly. Both patients made a satisfactory recovery. Somewhat similar symptoms, which, however, did not cause anxiety, developed in a third case, in which laryngoscopic examination proved that the vocal cords moved equally and well, and that the stridor was due to oedema of the hypopharynx and the upper part of the glottis. In this case the front of the neck seemed swollen as a result of accumulation of blood clot. On opening up the wound completely a large amount of clotted blood was found under tension, and a minute persistent oozing vessel on the front of the trachea was secured. The moderate degree of dyspnoea present was relieved by removal of the clot, and the patient's breathing was perfectly normal within a few hours. The details of these cases have been related in order to draw attention to a complication which may be encountered occasionally in any long series of thyroidectomy cases, and to emphasize the necessity for prompt recognition and immediate treatment.

Recurrent Nerve Paralysis.—No instance of either temporary or permanent paralysis of a vocal cord occurred in any of the cases in this series. In three cases limitation of one cord was noted on laryngoscopic examination before operation. In two of these recovery of movement of the cord was noted at a subsequent date.

Mental Symptoms.—Mental depression occurred in one case. The patient, who had suffered from primary toxic goitre for several years, was perfectly normal mentally until the tenth day after operation, when she became acutely melancholic and suffered from delusions. She was transferred to a mental home, from which she was discharged after a period of six weeks, having completely recovered her mental stability.

Tetany.—There were two cases of post-operative tetany. In the first case the symptoms were transient, and were confined to slight stiffness of the fingers, observed only on the first and fourth days after operation. Parathyroid extract and calcium were given for a period of two weeks. Thereafter no further signs of tetany were observed, and the patient has remained in excellent health. The second case was remarkable in that the symptoms of tetany did not appear until four months after operation, and no trace of parathyroid tissue could be detected in the resected lobes. Large doses of calcium were needed to

control the symptoms, and although it is now three years since her operation, the patient still requires to take calcium regularly. The general health is excellent, and the patient is in regular employment.

Myxoedema.—Signs of myxoedema developed in one case. There was no indication of thyroid insufficiency until three and a half years after the operation, when the weight became excessive and mental apathy was noted. This patient is now in excellent health, and requires to take only $1\frac{1}{2}$ grains of thyroid daily.

Results of Treatment

Since the main object of this paper is to present the results obtained by operative treatment in toxic goitre, we shall consider these in some detail. Out of a total of 125 cases 104 were examined personally by us when they presented themselves at hospital to report progress; a further ten patients were unable to report owing to distance or to family ties, and questionnaires were sent to these regarding their present state of health. In nine cases the operation has been performed too recently to allow of their inclusion in this section dealing with after-results. Two cases are untraced. Thus if we omit the nine cases which have been operated on during the last few months, we are left with a total of 116 cases, and we have information regarding the present state of health in 114 of these. For the purpose of discussing the after-effects of treatment, therefore, 114 will be taken as the total.

When an attempt is made to assess the results of treatment in a condition such as toxic goitre it is important to have some standard by which each individual case may be judged; and while, no doubt, we can to some extent gauge the degree of improvement by the disappearance of certain symptoms and signs, we are strongly of the opinion that the most valuable criterion of success or failure is the patient's general health and well-being. In this section dealing with the results of operative treatment, then, we shall first of all assess the patients according to their general health and fitness for work at the present time, and then the effect of operation on various symptoms and signs of toxic goitre will be considered. For the purpose of a general assessment certain symbols have been employed as follows:

S+++. The patients included in this group were completely symptom-free, and stated that they were able to carry out their usual employment without any effort.

S+. These patients stated that they were feeling very well and fit for their work, but still showed slight evidence of hyperthyroidism.

S. The patients thus classified showed definite improvement as a result of the operation but did not feel capable of a full day's work, there being definite persistence of toxic symptoms.

S-. This group comprises the failures, and includes patients who obtained little or no relief from their symptoms following operation or who showed definite signs of a recurrence of thyroid enlargement.

The above classification, founded as it is on personal impression, must necessarily be merely approximate. We would state, however, that great care was exercised both in the examination and in the questioning of each patient before the final assessment.

The following table shows the number of cases included under each heading and, in addition, the number of deaths is shown. These latter cases, in which the patient died as a result of the operation or on some subsequent occasion, are discussed further in another section.

S+++	72 or 63.2	} \$6.9 per cent.
S++	27 or 23.7	
S+	7 or 6.1	} per cent.
S	1 or 0.9	
Dead	7 or 6.1	"

This table reveals that 63.2 per cent. of those operated on are now completely restored to health and a further 23.7 per cent. are able to do a full day's work and remain practically symptom-free. Thus it may be said that highly satisfactory results have been obtained in 86.9 per cent. of cases.

Brief consideration of the patients in these groups may be of interest. Those classified S++ and S+ have been pronounced fit for their employment and, since the majority are women, the largest number are naturally engaged in housework. It is important to note that all the patients thus employed expressed themselves capable of the heaviest duties concerned with the management of their homes and not merely light household work. Regarding the time which elapsed following operation before the patients were able to resume their work our information is, unfortunately, incomplete. It is known, however, that 50 per cent. of the patients who are now fit for work were fully engaged in their various duties within one year of operation, and 30 per cent. were working within six months of operation. It is highly probable that these figures are considerably on the low side, and that resumption of work may usually be expected within six months of operation in successfully treated cases.

In the S group there are seven patients, and four of these are fit for light employment. The remaining three are able to go about, but any attempt at arduous work causes early fatigue. Study of these seven cases reveals that three have suffered from severe influenza or bronchitis since operation; two have had gynaecological operations, and two have had all their teeth extracted. The patients in this group have all gained weight since operation and show definite improvement in their general health, although persistence of a considerable degree of hyperthyroidism does not allow of their inclusion among the operation successes.

One patient has been classified S-, since, although there was some improvement following operation, there is now recurrence of thyroid enlargement and persistence of toxic symptoms.

Correlation of severity of symptoms with results of treatment may be conveniently shown thus:

	S++	S+	S	S-	Dead	Totals
Severe	15	9	2	0	5	31
Moderate	37	14	4	1	2	58
Mild	15	4	0	0	0	19
Unclassified	5	0	1	0	0	6
Totals	72	27	7	1	7	114

As would be expected, it is obvious from the above table that the best results are obtained in the moderate and mild cases.

Operation Mortality

In this series of 125 cases, four died as a result of the operation, representing a mortality rate of 3.2 per cent. In three of the cases death occurred on the day of operation, and the fourth died two days after operation. A brief description of these four cases may be of interest:

Case 1.—Mrs. C. W., aged 58 years. Duration, five years. Confined to bed for two years. Very feeble and exhausted, and weighed only 5 st. 3 lb. Operation: ligation of superior thyroid arteries under local anaesthesia. The decision to operate on this case was almost certainly an error of judgement.

Case 2.—Sarah D., aged 28 years. Duration, one year. B.M.R. + 90 per cent. Severe toxic symptoms. Operation: preliminary ligation of superior thyroid arteries followed by subtotal thyroidectomy with general anaesthesia. Post-mortem: fatty degeneration of liver with commencing necrosis of liver cells.

Case 3.—Andrew McL., aged 27 years. Duration, two years. B.M.R. + 59 per cent. Severe toxic symptoms. Operation: subtotal thyroidectomy with local and general anaesthesia. In this case death was possibly due to the pre-operative sedative, the patient appearing to have an idiosyncrasy to morphine and hyoscine.

Case 4.—Mrs. V., aged 50 years. Duration, two years, during which time she was confined to bed. Marked cardiac enlargement with auricular fibrillation. Operation: subtotal thyroidectomy under local anaesthesia. Died three hours after operation from sudden heart failure.

It will be noted that the operation fatalities occurred in the severest type of case. The four patients mentioned above had all received long courses of medical treatment without success before being referred to the surgical ward, and operation was only undertaken as a last resource.

In addition to the four patients who died as a direct result of the operation three have since died from other causes: two from diabetes mellitus, one and four years after operation respectively, and one from cardiac failure two years after operation. These three cases are not included under operation mortality, since, so far as can be determined, death was not in any way connected with the operation on the thyroid.

Effect of Operation on Certain Symptoms and Signs

When the patients reported at hospital following operation, notes were made regarding the presence or absence of certain of the commoner signs of toxic goitre. We would again emphasize, however, that we do not lay great stress on individual symptoms or signs, but rather on the patient's general well-being and fitness for work.

Exophthalmos.—In seventy-four cases where exophthalmos was present before operation we have information regarding the present state of affairs. This may be conveniently shown as follows:

Absent	Less	Unchanged	Total
25	41	8	74

It will be noted that exophthalmos was found to have disappeared in twenty-five out of seventy-four cases, or in 33.8 per cent., and in a further forty-one cases the degree of exophthalmos was considerably less than before operation.

Pulse Rate.—The pulse rate was recorded in each case before operation and on reporting at hospital after operation. The average rate for the total series before operation was 103 and after operation ninety-one—a difference of twelve per minute. It should be stated that these pulse rate figures are not strictly comparable, since the rate before operation represents the resting pulse rate after preparation for operation, whereas the post-operative rates were estimated when the patients reported at hospital, in some cases after a considerable journey. It was noted in a number of cases that tachycardia persisted for some months following operation, despite the fact that all other signs of hyperthyroidism had disappeared. A curious feature in connexion with the persistence of this symptom was that, in the great majority of cases, it did not appear to give rise to any discomfort and, in fact, the patients were usually quite unaware of its presence.

Auricular Fibrillation.—Auricular fibrillation was noted in ten cases at the time of operation, and we have information regarding all of these at the present time. In seven the pulse is now perfectly regular, and in one case the irregularity still persists eighteen months after operation, although the general health is excellent. The remaining two patients died, one on the day of operation and the other from cardiac failure two years after operation. Of the seven patients in whom the fibrillation ceased, five are now doing a full day's work without any discomfort and the remaining two are as yet only convalescing after their operation.

Weight.—A striking feature which was noted in almost every case was the gain in weight following operation. The average weight for the total cases before treatment was 120.5 lb., and the present average weight is 143.6 lb. Thus it will be seen that the average gain in weight amounted to nearly two stones. A point of interest in connexion with the weight is that many of the patients intimated that their weight rose rapidly during the first few months after operation and then tended to fall and become stabilized. The figures quoted here represent the stabilized weight and not the early rapid rise referred to.

Intercurrent Infections, etc.

When the patients reported they were questioned as to whether they had suffered from any illness since the operation on the thyroid. It transpired that thirty had suffered from some infection or prolonged worry subsequent to operation. Included in this number are two patients who have been confined and two who are at present in the late stages of pregnancy. A number of patients were found to have suffered from trivial ailments, but these have not been included, and it is only cases where confinement to bed for a considerable period was necessitated which are considered here. Out of the thirty patients mentioned above, twenty-three now enjoy excellent health and are fit for their employment despite intercurrent illness since operation. The remaining seven patients, to whom reference has previously been made, are all classified "S," and are not in a satisfactory state of health, although they assert that they feel better now than they did prior to operation. A point of interest arises in connexion with this question of intercurrent infection, since many of the patients remarked on their freedom from infections such as influenza and tonsillitis after the removal of the thyroid. Whereas previously they had been subject to frequent influenzal attacks, and the like, thyroidectomy appears to have increased their resistance to such infection.

Commentary

The treatment of toxic goitre is a subject which has given rise to much controversy in the past, and it is only in comparatively recent years, in this country at any rate, that surgery has been regarded with favour. Those who are averse to surgical intervention maintain that many cases may be cured by non-surgical measures, or that the operative risk is too great in proportion to the results obtained. There can be little doubt that many cases of toxic goitre may be greatly improved and even completely cured by medical treatment alone, but the admission of this fact should neither justify the adoption of medical treatment as a routine nor condemn operative treatment, since in most cases we are concerned not only with restoring the patient to health but with doing so as quickly as possible. Herein lies one of the great advantages of surgical treatment, since a high proportion of the patients thus treated are rapidly restored to good health and are enabled to return to their employment within a few months of operation. With non-surgical treatment, on the other hand, the patient may remain an invalid for many months, and at the end of this long period of inactivity there is no guarantee that she will be in a fit state to resume her normal activities. It is the uncertainty of medical treatment which is, in our opinion, its greatest disadvantage, since not only may there be little or no improvement as a result of such treatment, but there is a risk in some cases of actual deterioration in health with the lapse of time.

The question is frequently asked—What are the indications for operation in toxic goitre? It is now generally agreed that operation is indicated as a routine measure in all cases of secondary toxic goitre. It is in the

primary case that opinion is so divergent regarding the advisability of operative intervention. The decision for or against operation in any particular case must be a matter largely of personal opinion. We believe that, in our present state of knowledge, toxic goitre must be regarded as essentially a surgical condition, and as such should be treated by operation with the minimum of delay. This view is no doubt open to criticism, but it is felt that many patients are lost as a result of prolonged attempts to save them from the ordeal of operation by continuing measures which too often are of little or no avail. It is surely preferable to advise a patient with toxic goitre to submit herself to the slight risk of operation when her general health is comparatively good, rather than to temporize until perhaps there is permanent cardiac damage, and resistance is at its lowest ebb, and then as a last resource be compelled to advise surgical intervention.

The problem of operative risk is one which must always be considered when advising treatment in toxic goitre. If surgery is to be successful, scrupulous attention must be devoted both to the operative technique and to the details of the pre-operative and post-operative periods. The operation mortality of 3.2 per cent. in this series cannot be regarded as a very serious risk, and yet it is probable that this figure would have been lower if the patients could have been treated at an earlier stage of their illness. A considerable number came to operation in a very poor state of health, in spite of careful and prolonged medical treatment, and all the fatalities occurred in this type of case.

We would suggest that if the best results are to be obtained in the treatment of toxic goitre to-day, operation should be recommended at an early stage in all cases. Timely resort to surgery would ensure the complete restoration of health in the vast majority, and the number of fatalities would be reduced to a minimum. Furthermore, permanent cardiac damage as a complication would, in these circumstances, be almost entirely eliminated.

Summary

The results of surgical treatment are presented in a series of 125 consecutive cases of toxic goitre. Approximately 90 per cent. of the patients operated on are now fit for regular employment.

The operation of choice was subtotal thyroidectomy, performed under local anaesthesia with omnopon as a pre-operative sedative.

The operation mortality rate was 3.2 per cent. All the fatalities occurred in severe, long-standing cases which had been resistant to medical treatment.

It is suggested that, in our present state of knowledge, toxic goitre should be regarded as essentially a surgical condition, and that if this were done the operation mortality would be reduced to an extremely low figure, and rapid and complete restoration of health would be achieved in the vast majority of cases.

Changes have been made in the method of subscription by non-members to the afternoon lectures at the Royal Institution, 21, Albemarle Street, W. In future single lecture tickets will be sold at a charge of 3s. each. The new arrangements apply to all the afternoon lectures, except the Christmas lectures. Subscribers to a course will receive a book containing the appropriate number of single lecture tickets, the rates being 7s. 6d. for a course of three lectures and 10s. for a course of four. The tickets will be transferable, and a single lecture ticket not used for the course for which it has been issued will admit to a lecture of any other course. Season tickets will also be obtainable. The privileges of members of the Institution are not affected by these changes. Members are admitted without ticket to the afternoon lectures, and they can purchase books of single lecture tickets, to admit their friends, at privileged rates.

AN ACCOUNT OF OBSTETRIC METHODS AT ST. MARY ABBOTS HOSPITAL, KENSINGTON

WITH A COMMENT ON MATERNAL MORTALITY

BY

G. W. THEOBALD, M.D., M.R.C.P., F.R.C.S.ED.
F.C.O.G.

CONSULTANT OBSTETRICIAN AND GYNAECOLOGIST TO ST. MARY ABBOTS
HOSPITAL; LATE PROFESSOR OF OBSTETRICS AND GYNAECOLOGY,
BANGKOK; FORMERLY ASSISTANT MASTER, ROTUNDA
HOSPITAL, DUBLIN

Early in 1933 a number of wards, skilfully reconditioned and adapted, were opened in St. Mary Abbots Hospital for obstetric and gynaecological patients. This scheme was due to the zeal and imagination of the late medical superintendent of the hospital, Dr. Remington Hobbs, who unfortunately died without seeing the fruition of his plans. The fine gynaecological ward has been named after him, and his memory will be kept green.

The Arrangement of the Unit

As an experiment, and with the full concurrence of the medical superintendent, Mr. J. Carver, I was given entire professional control of the unit, and the purpose of this paper is to record the main results obtained in the maternity wards, and to draw certain conclusions from them. The delivery and lying-in wards for thirty-six patients are situated on the top floor. On the second floor there is an ante-natal ward containing fourteen beds. The gynaecological ward of twenty beds is on the ground floor, as is the "suspect" lying-in ward. All patients who have received ante-natal care, at whatever centre, are admitted straight to the top floor for confinement. All cases which have been tampered with outside, all B.B.A.'s, and all women with a heavy vaginal discharge, are confined to the ground floor and nursed in the "suspect" ward. Patients who have received no ante-natal care are admitted in the first instance to a side ward on the ground floor, and if found clean are transferred immediately to the top floor for confinement. Every patient admitted to the "suspect" ward is given an injection of 20 c.cm. of anti-streptococcal serum on the evening of delivery, and a further 20 c.cm. the next morning.

The rules and regulations governing the admission of patients and the minutiae of treatment to be carried out by the nursing staff are written in a ward book, and it is hoped that they will shortly be published. Reference will only be made here to those considered the more important. On admission, every patient commencing labour is given castor oil 3ij, which is followed by an enema some four hours later. A further enema is given towards the end of the second stage. Each patient is completely shaved, the razor being kept in pure lysol and an adequate supply of new blades assured. The breasts are thoroughly washed with soap and water, special attention being paid to the nipples, and then freely rinsed with a 1 in 1,000 solution of biniodide of mercury. After the breasts are dried the nipples are hardened with spirit. This treatment of the breasts is carried out as often as is convenient before delivery occurs.

The Ante-natal Ward

The ante-natal clinics are conducted by Miss P. N. Hooper, assisted by one or other of the resident medical officers. It has not been possible, mainly owing to expense, to put the patients on milk and cod-liver oil. All cases of contracted pelvis are brought up for a thorough examination in the hospital. All patients whose systolic blood pressure exceeds 140 mm. Hg, all cases

of albuminuria, and all other "toxaemic" or ill patients, are admitted to the ante-natal ward.

Here I would stress the point that the best results from ante-natal care can only be obtained if an adequate number of ante-natal beds are available. In this respect the unit is most fortunate. During the year some eighty patients were admitted to this ward because of toxaemic symptoms, not only from the ante-natal clinic but also from outside sources. The most interesting feature of these cases was the large number of patients suffering from hyperpiesis (the diastolic pressure often exceeding 100 mm. Hg) who never developed albuminuria. They will be reported elsewhere. Here it suffices to say that all these patients were kept all the time on a full hospital diet, including eggs, bacon, and fish, but excluding meat. They were given in addition vitamins A, B, and D; iron; thyroid extract by mouth; and calcium gluconate by intramuscular injection. Induction of labour was never considered, and all the mothers save three went out with living infants.

One, a young primigravida, was a clear case of chronic nephritis, and her premature infant died during the first week of its life. One infant was lost because it presented as a breech and died during delivery, while the third was stillborn through torsion of the cord. In any case the mother of the last child had a normal blood pressure, and there was no albumin in her urine.

The Labour Ward

The nurses when conducting a confinement wear a mackintosh apron which is carbolized between each case. They do not wear masks or gowns. In my opinion the theoretical evidence in favour of droplet infection is unconvincing, and it is certain that the hospitals which have consistently produced the best results offer it no support. The vulva is a small area, and for practical purposes it may be assumed that the organisms responsible for puerperal infection gain access through this narrow portal. If the vulva is kept antiseptic during the second stage of labour and during delivery infection cannot and does not occur. *Antisepsis, not asepsis, is the key to safe midwifery.*

The antiseptic employed is a 1 in 1,000 aqueous solution of biniodide of mercury. A pair of tongue-forceps is kept in a jar of lysol (the handles protruding) by the side of the patient. During the whole course of labour the nurse keeps the vulva not only clean, but antiseptic, by means of swabs taken out of the biniodide solution and held in forceps. My teacher, Dr. Gibbon FitzGibbon, has estimated that each delivery requires a gallon of biniodide solution. This figure is considerably exceeded in this unit.

Management of the Delivery

During delivery no sterile sheets, stockings, or towels are used. The vulva is cleaned with swabs out of biniodide solution from before backwards after every pain, the swabs being held in a pair of sterile forceps. In between the pains the midwife stands with both gloved hands immersed in biniodide solution. When the head is crowned, and not before, she places three fingers on the head to prevent it being born with a rush. At no time during the delivery should the fingers of the attendant touch the vulva or perineum of the patient. This method, which I have described as the "modified Garden of Eden" method of delivery, is perfectly safe. The child's eyes are cleaned with swabs out of biniodide of mercury. The fundus of the uterus is not controlled during the third stage, for it can be seen. Leaving the fundus of the uterus severely alone does not lead to, but prevents, post-partum haemorrhage. Two drachms of the liquid extract of ergot are given as soon after the placenta is delivered as possible.

Sterilization of Gloves

Each pupil midwife has a pair of well-fitting rubber gloves, which she keeps in a tin labelled with her name. After washing her hands and rinsing them in biniodide solution she dries them on a clean towel. Before putting the gloves on she tests them to see that they are not punctured. After they are on she scrubs them under running water with soap, using a nail-brush. The gloved hands are soaked and rubbed together in the biniodide solution before a vaginal examination is made. After the vaginal examination the nurse washes the gloves and proceeds to make a rectal examination. She thus learns that she can find out almost as much by rectal as by vaginal examination.

There can be few who would contradict any of the three following assertions: (1) vaginal examinations are completely unnecessary during the course of a normal labour; (2) most surgeons are less willing to perform Caesarean section after one or more vaginal examinations have been made; (3) a vaginal examination made by the average midwife in private practice is a very different thing from a vaginal examination made under supervision in hospital. It is therefore astonishing that midwives are still not only allowed but compelled to make vaginal examinations during their training. Here is one source of mortality which could easily be eliminated.

The rectal examination made, the nurse holds the soiled finger under a stream of water until the gross soil is removed, and then proceeds to scrub her gloved hands in the manner described, soaks them in biniodide, powders them, and takes them off. The sterile outside of each glove becomes the inside on the next occasion they are used. After again testing them for punctures the gloves are replaced in the tin. The insistence on invariably using the nail-brush is because vernix caseosa and blood cannot be removed without its aid. Two gloves are always worn when making a rectal examination.

This method of sterilizing gloves, described by Theobald and Bigger,² has been successfully used in many institutions in different parts of the world. Apart from the value of the method in obstetric practice the saving on glove expenditure in a large hospital is very considerable. Colebrook³ has confirmed our findings. The gloves can not only be made absolutely sterile, but definitely antiseptic. Oxley does not use rubber gloves, and I agree with him that they are not essential for normal midwifery, providing it can be guaranteed that all the patients are clean. Halsted introduced gloves for the protection of the sister who afterwards became his wife. I do not know whether many patients at the East End Maternity Hospital suffer from acute venereal disease or gross vaginal discharge, but I am convinced that gloves are essential, primarily to protect the midwife, and secondarily to protect subsequent patients.

The Conduct of a Difficult Case

The following two truths may be enunciated: (1) A low forceps rate is dependent more on the conduct of the first stage of labour than on anything which can be done during the second stage. (2) Other things being equal, the longer a woman remains in labour the greater her chance of becoming infected. In my opinion the secret of a normal issue in difficult cases is dependent on the judicious use of morphine, scopolamine, and quinine. Each patient starting labour at night is given an injection of morphine sulphate grain 1/4, and scopolamine hydrobromide grain 1/100. If when she awakens in the morning the pains are poor, quinine hydrochloride grains 10 is given by mouth. The quinine may be repeated if neces-

sary in three hours. In some cases quinine hydrochloride grains 5 given three-hourly changes moderate into good "pains."

It is a common fallacy to regard the action of quinine as antagonistic to that of scopolamine. Slow dilatation of the cervix is due to inhibitory stimuli from the brain. These are cut off by the scopolamine, while the quinine augments the force of the uterine contractions. Quinine diminishes the anxiety associated with primary uterine inertia, but should not be given until the head is engaged unless the obstetrician is certain that it can pass through the pelvis. Quinine can and has caused rupture of the uterus. There can be little doubt that the value of this drug in toning up the uterus during the last few weeks of pregnancy and in increasing the force of the uterine contractions during labour is not fully realized in this country.

Conduct of the Puerperium

Each patient is given castor oil ʒij on the morning after delivery and a purgative on each subsequent night that she spends in hospital. She is encouraged to sit bolt upright in bed at frequent intervals, and is not hampered by any binder. The perineal toilet is made in the following manner.

The nurse wears gloves, but holds all the swabs she uses in a pair of tongue forceps. The patient is placed, suitably draped, on a douche pan. The soil is washed away with swabs out of weak lysol (half a drachm to the pint). A jug of biniodide solution is then poured over the vulva. The thighs and buttocks are dried, and the dry sterile pad is placed on the "wet" vulva. Particular attention is devoted to the bedpans. Each pan is flushed after use. The rim is then swabbed with pure lysol. The pan is subsequently immersed in a strong solution of lysol for at least ten minutes before it is again used. Silver catheters are employed exclusively, no rubber one being allowed in the wards.

Every patient is given potassium citrate until the urine becomes alkaline, and it is kept alkaline for some days. I have long been convinced that infection of the urinary tract usually precedes or is causally associated with puerperal infection. In any case the *Bacillus coli* can be cultured from the urines of from 10 to 20 per cent. of all puerperal patients. It is my belief that purgation and rendering the urine alkaline are two of the most important measures which can be adopted to prevent morbidity.

Attention has already been drawn to the treatment of the breasts on admission. Before and after each feed the nipples are washed with boric solution and subsequently with glycerin and borax. The swabs used for this purpose are held in a pair of sterile forceps. If the nipple is cracked it is treated at frequent intervals with spirit. Towels, somewhat similar to those used for circumcision, are daily provided for each patient. The nipple, after being cleaned, protrudes through the hole in the towel, and is thereby prevented from being contaminated by the blankets and nightdress. Further, great care is taken to see that the nails of the patients are kept short and clean. Each mother washes her hands and soaks them in biniodide before feeding her infant.

I maintain that a temperature of 98.4°F . during the puerperium is pathological, particularly if it occurs in the morning. More than 90 per cent. of the patients never recorded a temperature of 98.4° during their stay in hospital. Morbidity is the true index of the standard of work in a maternity hospital, and the attainment of a low morbidity rate demands the utmost vigilance, attention to detail, and something of the powers of a detective on the part of the obstetrician in charge.

AN ACCOUNT OF OBSTETRIC METHODS AT ST. MARY ABBOTS HOSPITAL, KENSINGTON

WITH A COMMENT ON MATERNAL MORTALITY

BY

G. W. THEOBALD, M.D., M.R.C.P., F.R.C.S.ED.
F.C.O.G.

CONSULTANT OBSTETRICIAN AND GYNAECOLOGIST TO ST. MARY ABBOTS
HOSPITAL; LATE PROFESSOR OF OBSTETRICS AND GYNAECOLOGY,
BANGKOK; FORMERLY ASSISTANT MASTER, ROTUNDA
HOSPITAL, DUBLIN

Early in 1933 a number of wards, skilfully reconditioned and adapted, were opened in St. Mary Abbots Hospital for obstetric and gynaecological patients. This scheme was due to the zeal and imagination of the late medical superintendent of the hospital, Dr. Remington Hobbs, who unfortunately died without seeing the fruition of his plans. The fine gynaecological ward has been named after him, and his memory will be kept green.

The Arrangement of the Unit

As an experiment, and with the full concurrence of the medical superintendent, Mr. J. Carver, I was given entire professional control of the unit, and the purpose of this paper is to record the main results obtained in the maternity wards, and to draw certain conclusions from them. The delivery and lying-in wards for thirty-six patients are situated on the top floor. On the second floor there is an ante-natal ward containing fourteen beds. The gynaecological ward of twenty beds is on the ground floor, as is the "suspect" lying-in ward. All patients who have received ante-natal care, at whatever centre, are admitted straight to the top floor for confinement. All cases which have been tampered with outside, all B.B.A.'s, and all women with a heavy vaginal discharge, are confined to the ground floor and nursed in the "suspect" ward. Patients who have received no ante-natal care are admitted in the first instance to a side ward on the ground floor, and if found clean are transferred immediately to the top floor for confinement. Every patient admitted to the "suspect" ward is given an injection of 20 c.cm. of anti-streptococcal serum on the evening of delivery, and a further 20 c.cm. the next morning.

The rules and regulations governing the admission of patients and the minutiae of treatment to be carried out by the nursing staff are written in a ward book, and it is hoped that they will shortly be published. Reference will only be made here to those considered the more important. On admission, every patient commencing labour is given castor oil 3ij, which is followed by an enema some four hours later. A further enema is given towards the end of the second stage. Each patient is completely shaved, the razor being kept in pure lysol and an adequate supply of new blades assured. The breasts are thoroughly washed with soap and water, special attention being paid to the nipples, and then freely rinsed with a 1 in 1,000 solution of biniodide of mercury. After the breasts are dried the nipples are hardened with spirit. This treatment of the breasts is carried out as often as is convenient before delivery occurs.

The Ante-natal Ward

The ante-natal clinics are conducted by Miss P. N. Hooper, assisted by one or other of the resident medical officers. It has not been possible, mainly owing to expense, to put the patients on milk and cod-liver oil. All cases of contracted pelvis are brought up for a thorough examination in the hospital. All patients whose systolic blood pressure exceeds 140 mm. Hg, all cases

of albuminuria, and all other "toxaemic" or ill patients, are admitted to the ante-natal ward.

Here I would stress the point that the best results from ante-natal care can only be obtained if an adequate number of ante-natal beds are available. In this respect the unit is most fortunate. During the year some eighty patients were admitted to this ward because of toxaemic symptoms, not only from the ante-natal clinic but also from outside sources. The most interesting feature of these cases was the large number of patients suffering from hyperpiesis (the diastolic pressure often exceeding 100 mm. Hg) who never developed albuminuria. They will be reported elsewhere. Here it suffices to say that all these patients were kept all the time on a full hospital diet, including eggs, bacon, and fish, but excluding meat. They were given in addition vitamins A, B, and D; iron; thyroid extract by mouth; and calcium gluconate by intramuscular injection. Induction of labour was never considered, and all the mothers save three went out with living infants.

One, a young primigravida, was a clear case of chronic nephritis, and her premature infant died during the first week of its life. One infant was lost because it presented as a breech and died during delivery, while the third was stillborn through torsion of the cord. In any case the mother of the last child had a normal blood pressure, and there was no albumin in her urine.

The Labour Ward

The nurses when conducting a confinement wear a mackintosh apron which is carbolized between each case. They do not wear masks or gowns. In my opinion the theoretical evidence in favour of droplet infection is unconvincing, and it is certain that the hospitals which have consistently produced the best results offer it no support. The vulva is a small area, and for practical purposes it may be assumed that the organisms responsible for puerperal infection gain access through this narrow portal. If the vulva is kept antiseptic during the second stage of labour and during delivery infection cannot and does not occur. Antisepsis, not asepsis, is the key to safe midwifery.

The antiseptic employed is a 1 in 1,000 aqueous solution of biniodide of mercury. A pair of tongue-forceps is kept in a jar of lysol (the handles protruding) by the side of the patient. During the whole course of labour the nurse keeps the vulva not only clean, but antiseptic, by means of swabs taken out of the biniodide solution and held in forceps. My teacher, Dr. Gibbon FitzGibbon, has estimated that each delivery requires a gallon of biniodide solution. This figure is considerably exceeded in this unit.

Management of the Delivery

During delivery no sterile sheets, stockings, or towels are used. The vulva is cleaned with swabs out of biniodide solution from before backwards after every pain, the swabs being held in a pair of sterile forceps. In between the pains the midwife stands with both gloved hands immersed in biniodide solution. When the head is crowned, and not before, she places three fingers on the head to prevent it being born with a rush. At no time during the delivery should the fingers of the attendant touch the vulva or perineum of the patient. This method, which I have described as the "modified Garden of Eden" method of delivery, is perfectly safe. The child's eyes are cleaned with swabs out of biniodide of mercury. The fundus of the uterus is not controlled during the third stage, for it can be seen. Leaving the fundus of the uterus severely alone does not lead to, but prevents, post-partum haemorrhage. Two drachms of the liquid extract of ergot are given as soon after the placenta is delivered as possible.

Sterilization of Gloves

Each pupil midwife has a pair of well-fitting rubber gloves, which she keeps in a tin labelled with her name. After washing her hands and rinsing them in biniodide solution she dries them on a clean towel. Before putting the gloves on she tests them to see that they are not punctured. After they are on she scrubs them under running water with soap, using a nail-brush. The gloved hands are soaked and rubbed together in the biniodide solution before a vaginal examination is made. After the vaginal examination the nurse washes the gloves and proceeds to make a rectal examination. She thus learns that she can find out almost as much by rectal as by vaginal examination.

There can be few who would contradict any of the three following assertions: (1) vaginal examinations are completely unnecessary during the course of a normal labour; (2) most surgeons are less willing to perform Caesarean section after one or more vaginal examinations have been made; (3) a vaginal examination made by the average midwife in private practice is a very different thing from a vaginal examination made under supervision in hospital. It is therefore astonishing that midwives are still not only allowed but compelled to make vaginal examinations during their training. Here is one source of mortality which could easily be eliminated.

The rectal examination made, the nurse holds the soiled finger under a stream of water until the gross soil is removed, and then proceeds to scrub her gloved hands in the manner described, soaks them in biniodide, powders them, and takes them off. The sterile outside of each glove becomes the inside on the next occasion they are used. After again testing them for punctures the gloves are replaced in the tin. The insistence on invariably using the nail-brush is because vernix caseosa and blood cannot be removed without its aid. Two gloves are always worn when making a rectal examination.

This method of sterilizing gloves, described by Theobald and Bigger,² has been successfully used in many institutions in different parts of the world. Apart from the value of the method in obstetric practice the saving on glove expenditure in a large hospital is very considerable. Colebrook³ has confirmed our findings. The gloves can not only be made absolutely sterile, but definitely antiseptic. Oxley does not use rubber gloves, and I agree with him that they are not essential for normal midwifery, providing it can be guaranteed that all the patients are clean. Halsted introduced gloves for the protection of the sister who afterwards became his wife. I do not know whether many patients at the East End Maternity Hospital suffer from acute venereal disease or gross vaginal discharge, but I am convinced that gloves are essential, primarily to protect the midwife, and secondarily to protect subsequent patients.

The Conduct of a Difficult Case

The following two truths may be enunciated: (1) A low forceps rate is dependent more on the conduct of the first stage of labour than on anything which can be done during the second stage. (2) Other things being equal, the longer a woman remains in labour the greater her chance of becoming infected. In my opinion the secret of a normal issue in difficult cases is dependent on the judicious use of morphine, scopolamine, and quinine. Each patient starting labour at night is given an injection of morphine sulphate grain 1/4, and scopolamine hydrobromide grain 1/100. If when she awakens in the morning the pains are poor, quinine hydrochloride grains 10 is given by mouth. The quinine may be repeated if neces-

sary in three hours. In some cases quinine hydrochloride grains 5 given three-hourly changes moderate into good "pains."

It is a common fallacy to regard the action of quinine as antagonistic to that of scopolamine. Slow dilatation of the cervix is due to inhibitory stimuli from the brain. These are cut off by the scopolamine, while the quinine augments the force of the uterine contractions. Quinine diminishes the anxiety associated with primary uterine inertia, but should not be given until the head is engaged unless the obstetrician is certain that it can pass through the pelvis. Quinine can and has caused rupture of the uterus. There can be little doubt that the value of this drug in toning up the uterus during the last few weeks of pregnancy and in increasing the force of the uterine contractions during labour is not fully realized in this country.

Conduct of the Puerperium

Each patient is given castor oil \bar{z} ij on the morning after delivery and a purgative on each subsequent night that she spends in hospital. She is encouraged to sit bolt upright in bed at frequent intervals, and is not hampered by any binder. The perineal toilet is made in the following manner.

The nurse wears gloves, but holds all the swabs she uses in a pair of tongue forceps. The patient is placed, suitably draped, on a douche pan. The soil is washed away with swabs out of weak lysol (half a drachm to the pint). A jug of biniodide solution is then poured over the vulva. The thighs and buttocks are dried, and the dry sterile pad is placed on the "wet" vulva. Particular attention is devoted to the bedpans. Each pan is flushed after use. The rim is then swabbed with pure lysol. The pan is subsequently immersed in a strong solution of lysol for at least ten minutes before it is again used. Silver catheters are employed exclusively, no rubber one being allowed in the wards.

Every patient is given potassium citrate until the urine becomes alkaline, and it is kept alkaline for some days. I have long been convinced that infection of the urinary tract usually precedes or is causally associated with puerperal infection. In any case the *Bacillus coli* can be cultured from the urines of from 10 to 20 per cent. of all puerperal patients. It is my belief that purgation and rendering the urine alkaline are two of the most important measures which can be adopted to prevent morbidity.

Attention has already been drawn to the treatment of the breasts on admission. Before and after each feed the nipples are washed with boric solution and subsequently with glycerin and borax. The swabs used for this purpose are held in a pair of sterile forceps. If the nipple is cracked it is treated at frequent intervals with spirit. Towels, somewhat similar to those used for circumcision, are daily provided for each patient. The nipple, after being cleaned, protrudes through the hole in the towel, and is thereby prevented from being contaminated by the blankets and nightdress. Further, great care is taken to see that the nails of the patients are kept short and clean. Each mother washes her hands and soaks them in biniodide before feeding her infant.

I maintain that a temperature of 98.4° F. during the puerperium is pathological, particularly if it occurs in the morning. More than 90 per cent. of the patients never recorded a temperature of 98.4° during their stay in hospital. Morbidity is the true index of the standard of work in a maternity hospital, and the attainment of a low morbidity rate demands the utmost vigilance, attention to detail, and something of the powers of a detective on the part of the obstetrician in charge.

Anti-streptococcal Serum*

It has already been stated that every patient delivered on the ground floor and nursed in the suspect ward was given an injection of 40 c.cm. of anti-streptococcal serum. In 1926 I reported that seventy-six consecutive cases admitted to the Leeds Maternity Hospital, after gross interference outside, were given this amount of serum, and of this number four patients died and fifty-seven had a normal puerperium. Since then I have regularly employed it in all contaminated cases. The extraordinarily low morbidity rate obtained in the suspect ward, which for many reasons was extremely difficult to run, confirms the view that the prophylactic use of anti-streptococcal serum is of immense value.

Abortion and Miscarriages

It is only because I believe that the late Dr. Remington Hobbs would wish truth to take precedence of sentiment that I venture to make the following remarks about the glycerin treatment. In his day this treatment was given to every woman after confinement, and I can only conclude that it in some measure contributed to the high morbidity rates he recorded. No maternity patient has been given glycerin during the last twelve months and only four simple intrauterine douches with weak lysol, followed by flavine 1 in 500, have been given.

I hesitated to stop this treatment for abortion and miscarriage, and was open to be convinced of its efficacy. A large number of patients are admitted to the gynaecological ward in whom abortion or miscarriage is inevitable. The vast majority of them are single women, and in nearly every case the abortion is due to criminal interference. Some women take drugs for which they pay an extortionate price. Others douche themselves with soap-water or lysol, and most succeed in introducing the nozzle into the cervical canal; while still others favour the use of sticks of slippery elm, which they introduce into the cervix. Still others pay large sums of money to doctors, midwives, and abortionmongers, and the latest method in vogue is to introduce a "lamp" into the vaginal. Many of the patients were admitted with a high temperature. Now the glycerin treatment of such a patient is laborious, costly, and of long duration. The temperature often remains high for days, and even rises some days after the treatment is begun. Further, the placenta does not always come away. Glycerin is not irritant, neither is it definitely antiseptic, while its hygroscopic action is too weak to have any effect on the tissues. We have therefore gone back to the old-fashioned treatment. Every patient admitted with bleeding is examined per vaginam. If abortion is inevitable the uterus is emptied with the gloved finger with or without an anaesthetic. The uterus is not douched for fear of carrying the infection into the Fallopian tubes. Each patient is given 40 c.cm. of anti-streptococcal serum. The results obtained by this treatment are summarized as follows. Of 113 patients admitted between January and September of this year only one died. She was admitted moribund and in extreme pain, and died a few hours later. In the majority of cases the temperature fell as soon as the uterus was emptied, and the average stay in hospital was short.

Only one patient was drained. Two or three hours after the placenta had been removed from the cervical canal, without an anaesthetic, Dr. Craig decided that she had pus in the abdominal cavity. A small incision was made in the abdomen, through which a drainage tube was inserted. It is of interest to note that this was one of the few patients who had not attempted to terminate the pregnancy whether *per alia* or *per se*.

* Streptococcus antitoxin (concentrated), Scarlatina. L.C.C. Belmont Laboratories.

There can therefore be no doubt that the best method of treating cases of inevitable abortion which do not terminate spontaneously is to empty the uterus, using the finger and eschewing the curette and the douche. There can also be little doubt that the prophylactic use of anti-streptococcal serum is of great value, for convalescence was not as a rule complicated by pyrexia.

Maternal Mortality

During the first twelve months of this arrangement 846 patients were delivered of 856 babies, 393 of the women being primigravidae and 453 multigravidae. Of this number 746 were delivered on the top floor and 100 in the suspect ward. Of the patients delivered in the hospital four died.

CASE RECORDS

The first patient, a 2-gravida, was a case of "failed forceps," admitted from outside and with a badly ruptured uterus. She survived hysterectomy, performed the same day (but after the onset of peritonitis), six weeks, and then died from toxic absorption.

The second case was that of an ante-natal patient who died from eclampsia. She only paid three visits to the ante-natal clinic, the last being fourteen days before her death. At that visit nothing abnormal was discovered. Three days later she apparently fell ill, complained of headache and severe abdominal pain, and sent for her doctor. She did not come to the hospital until ten days later, during the whole of which time she had been ill. Shortly after admission she had a fit, and within two hours of this convulsion died, undelivered. The liver showed the classical lesions, and the right ventricle of the brain was occupied by a large haemorrhage.

The third patient died of circulatory failure. She was a 3-gravida, 32 years of age. Early in pregnancy she had a severe attack of pleurisy. She was repeatedly urged to come into the ante-natal ward, but refused, and insisted on remaining under the care of her own doctor. On admission oedema extended from the feet to the umbilicus. She was cyanosed and dyspnoeic. Labour was very short and easy, and her condition appeared to improve during the subsequent three days. Marked oedema of the right leg then developed; the urine contained albumin 0.9 per cent.; mental symptoms supervened; and she died on the twelfth day after delivery, her temperature having remained normal. This patient ought to have been sterilized after her last confinement, but there can be little doubt that pregnancy merely hastened the inevitable by a few months at the most.

The fourth patient was a primigravida 28 years of age. The pelvis was large; nevertheless the foetus died *in utero* a few hours after the rupture of the membranes. Later a well-marked contraction ring could be seen through the abdominal wall, just below the umbilicus. Under an anaesthetic the cervix was found to be fully dilatable, but the hand could not be passed above the contraction ring. Both arms were extended, and the cord was twisted twice round the neck. Two ampoules of amyl nitrite were broken under a mask and delivery effected, much difficulty being experienced with the shoulders. The blood pressure fell incontinently after the amyl nitrite had been given, and remained at an extremely low level, in spite of all treatment, until death occurred within two hours after delivery.

Maternal Morbidity

Of the 846 patients only fifteen were morbid as judged by the B.M.A. standard.⁴ Seeing that this standard is no less abused than used its definition will be given:

"The table of puerperal morbidity should include all fatal cases and also all cases in which the temperature reaches 100° F. on any two of the bi-daily readings from the end of the first to the end of the eighth day after delivery."

It is, moreover, demanded that the temperature be taken in the mouth, and that the thermometer be left in the mouth for four minutes. In this unit half-minute thermometers were employed and kept in the mouth for three minutes. Further, four-hourly temperature charts were kept for each patient, so that no morbidity escaped unnoticed.

Of these fourteen patients no fewer than seven were admitted with pyrexia. The case of ruptured uterus has been mentioned: the six others had booked for the maternity wards of other hospitals. Two patients were admitted with lobar pneumonia, in one case complicated by otitis media; one had acute pulmonary tuberculosis; one was a case of influenza and bacilluria; one had acute venereal infection of the vulva; and the sixth had severe haematuria, albuminuria, and pyuria, possibly due to drugs taken with a view to terminating the pregnancy. If these seven cases and the other three deaths be excluded it will be seen that of 836 cases only five were morbid. In one case the temperature was definitely due to an influenzal cold, and in another to a right pleural effusion, which occurred on the seventh day of the puerperium, and was almost certainly tuberculous.

Operative Intervention

Induction of Labour.—The uterus was emptied early in pregnancy on two occasions, once for old-standing and severe chorea, and once for active tuberculosis with rapidly extending lupus. The membranes were ruptured at term on three occasions, twice because of changing presentation associated with pendulous belly and a slight excess of liquor amnii, and once in a multigravida whose first baby was born dead, as the simplest means of avoiding post-maturity. Quinine was given on many occasions to induce labour at term to prevent post-maturity and bed wastage. On no occasion was induction of labour carried out as a therapeutic measure because of either contracted pelvis or toxæmic symptoms.

Caesarean Section.—Caesarean section was performed once for central placenta praevia in a primigravida, aged 34, whose baby weighed over 8 lb.

The Forceps.—The forceps were applied on twenty-nine occasions, twenty-two of the patients being primigravidae and seven multigravidae. In nearly every case the head was at the outlet before the forceps were applied. Two infants were born dead, and two died on the fourth day from intracranial haemorrhage. The forceps rate was therefore under 3.5 per cent., but nevertheless, in my opinion, too high.

Infant Mortality

The fact that over 800 confinements were conducted without recourse either to Caesarean section or to the induction of premature labour for contracted pelvis makes it necessary to prove that the conservative treatment was not associated with a high foetal mortality.

DETAILS OF CASES

Sixty-one babies were either born dead or died in the hospital. Of this number, twenty-six were of thirty weeks' gestation or under (no fewer than twenty-four being admitted as emergencies); fourteen were dead on admission, eight being macerated; one premature infant was stillborn, and five others died in hospital; one hydrocephalic skull was perforated; and one microcephalic infant died from atelectasis. This leaves thirteen cases to be accounted for. One was a breech; two babies were lost through torsion of the cord. Three infants with normal vertex presentations were born dead after easy labours, and post-mortem examinations did not reveal the causes of death: one infant weighed 13½ lb., the head was born normally, but delay occurred with the shoulders. An infant with a face presentation was lost because one arm was in the posterior nuchal position, and the cord was not only round the neck, but also round the trunk, where it was tightly clutched in the infant's hand. One primigravida had an extremely pendulous abdomen, and was mentally deficient. She refused to wear a binder or do as she was told. Somewhat late in labour I decided to perform internal version, but difficulty with the anaesthetic at a crucial point in the operation resulted in death of the infant before the version was completed. Subsequent delivery of the breech was not difficult. Two infants died from cerebral haemorrhage four days after delivery with the forceps.

Two infants delivered with the forceps were stillborn; in one case the woman had already had two living babies, and the difficulty was probably to do with the shoulders; the other was a case of primary uterine inertia. The forceps were applied many hours too late. The head was well down in the pelvis from the commencement of labour. The foetus of the patient who had a contraction ring died *in utero*.

Thus, of sixty-eight stillbirths and neo-natal deaths, twenty-six occurred in pregnancies of thirty weeks or under (most foetuses weighing about a pound); fourteen were dead on admission; one was hydrocephalic and another microcephalic; and six were markedly premature (three being twins). A careful review of the remaining thirteen cases does not reveal any case where the death of the foetus was due to lack of operative intervention.

A considerable number of cases of contracted pelvis were, however, delivered normally. One patient—whose external measurements were interspinous 9½ in., inter-crystal 10½ in., and external conjugate 6 in.—delivered herself normally of a female child weighing 6 lb.; while two patients who had previously been subjected to Caesarean section because of contracted pelvis were allowed to go to term. The one delivered herself spontaneously, and the other was delivered with the forceps.

During the year thirteen infants were delivered in the occipito-posterior position, three of the mothers being primigravidae and ten multigravidae. In only one case—that of a primigravida, was the application of the forceps necessary. The largest baby to be born spontaneously in this position weighed 9 lb. 12 oz., and more than half the number weighed over 7 lb.

Manceuvre for Estimating Whether Head will Pass Through Pelvis

I do not believe in the trial of labour, because I am convinced that it is possible to decide at the thirty-sixth or the thirty-eighth week of pregnancy whether the head will be able to pass through the pelvis or not. It may be necessary to put the patient under an anaesthetic, but this was not found necessary in any of these cases. There would appear to be no doubt that the commonest source of error in making this estimation is to be attributed to the anteriorly projecting promontory of the sacrum.

The external measurements may be small. The head feels very large and hard, rides in front of the pubic bone, and cannot be pushed into the pelvic inlet. The patient is placed in the lithotomy position. Two or more fingers of the right hand are introduced into the vagina, while the left hand grasps the head by a reversed Pawlik's grip. The assistant sinks both hands behind the fundus of the uterus and lifts it forwards.

By this manceuvre, which I have not seen described elsewhere, the head can be pushed into the pelvic inlet. If the assistant merely pushes the fundus downwards the head overrides the pubic bone. It is for this reason that a binder during labour, advocated by some writers, is strongly contraindicated. Instead, the woman should sit up or adopt any convenient attitude which allows the fundus to fall forwards. In this type of case the head tends to remain well above the pelvic inlet until the cervix is at least half dilated, and until after the rupture of the membranes. It follows that in such a case a "trial of labour" is useless unless the attendant waits until an hour or two after the rupture of the membranes. I think, too, that the width of the pubic bone gives some help in estimating the difficulty of any given labour.

Comment and Discussion

I have reported what I believe to be the lowest morbidity rate that has been published by any maternity unit or hospital in the country, and have shown that

over 800 consecutive confinements could be conducted without resorting either to induction of labour or to Caesarean section in the treatment of contracted pelvis or of the toxæmias of pregnancy. The forceps rate, which I admit as being too high, was under 3.5 per cent. An analysis of the stillbirths and neo-natal deaths compares very favourably with those of other institutions whose reports I have studied. It can, moreover, be fairly claimed that the material was of more than average difficulty. A very high proportion of the patients were unmarried, and many of them tried to hide themselves during pregnancy and received no ante-natal care. Many were sent in as emergencies, and not a few who were booked for other institutions were sent to this hospital.

The peculiar problems associated with the management of an obstetric unit are not fully appreciated by practitioners of other branches of medicine. That obstetrics is a subject which deals entirely with emergencies is forgotten. The very fact that 90 per cent. of all cases can be dealt with by midwives merely makes the art of dealing with the abnormal cases more difficult to acquire, while the constant stream of normal cases is apt to put the obstetrician off his guard. Whitridge Williams laid it down that a man could not obtain an adequate training in obstetrics unless he resided for at least three years in a maternity hospital, where he assumed he would have the opportunity of expert guidance and instruction by day and by night. Jellett, in his book *Maternal Mortality*, stresses the same point.

There is another aspect of the question. Of recent years more than a thousand ante-natal clinics have been opened in England and Wales, and Browne¹ estimates that at least 80 per cent. of all pregnant women receive ante-natal care. More than 7,000 beds are devoted to maternity cases, many "consultants" and "specialists" have been appointed, and millions of pounds have been expended. Sensible changes in clothing, various Factory and Shop Closing Acts, and the increasing pursuit of open-air exercise have contributed to improve the physique and health, if not the stamina, of the women throughout the country. Thanks to the work of Mellanby, serious rickets is yearly becoming rarer, and is hardly encountered in the South of England. In spite of all these factors the maternal mortality rate for 1933 was the highest for many years. Even the mortality rate from the toxæmias of pregnancy shows no decline, while the ratio of stillbirths to live births is not decreasing. Browne (1934) has quoted figures which suggest that the mortality rate from eclampsia shows a slight improvement in the years 1931 and 1932. Reference to the *Manual of the International List of Causes of Death*, however, reveals that a transference of causes of death in the toxæmic group was made from one heading to another, and this change first appeared in the statistical reports in 1931. The heading "Puerperal albuminuria and convulsions" does not include the same certified causes of death as in previous years, and it is therefore necessary, in order to obtain comparable rates, to add the mortality rates from "Puerperal albuminuria and convulsions" to those for "Other toxæmias of pregnancy." It will then be seen that the mortality rate from the toxæmias of pregnancy was higher in 1932 than in 1921.

Unless my view is correct,* that the toxæmias of pregnancy are deficiency diseases and may be prevented by seeing that each woman takes at least a pint of milk, a dessertspoonful of cod-liver oil, and vitamin B in some form or other throughout pregnancy, and is given an injection of calcium gluconate at the thirty-sixth and

thirty-eighth weeks of pregnancy, then there is no evidence that the mortality rate from this cause can be affected by ante-natal care as at present organized. Nobody can deny that ante-natal care is in itself ideal and proper, particularly if it is supported by an adequate number of ante-natal beds. Neither can anybody deny that the results obtained by the Rotunda Hospital, the East End Maternity Hospital, the Queen's Jubilee Nurses, and other institutions, prove conclusively that no 'change in the habits and customs of the woman is responsible for the increased maternal mortality. The argument that the higher proportion of primigravidae confined is responsible for the worsening results is for the same and other reasons unconvincing. The logical conclusion of the whole matter is that the increased mortality is due to increased operative intervention.

I would submit that there are two fundamental questions which require answer from the obstetricians and medical statesmen: (1) Is it true that unnecessary operative intervention inevitably leads to increased morbidity and mortality? (2) Is it true that an individual cannot acquire a sound conservative knowledge of obstetrics unless he resides for at least three years in a large maternity hospital under expert guidance? If these two questions be answered in the affirmative then it follows that the more money spent, the more ante-natal clinics opened, the more maternity beds provided, the more "consultants" and "specialists" appointed, the more certainly will the mortality rate from childbirth exceed five per thousand in 1944.

Summary

1. Over 800 patients were confined without resorting either to Caesarean section or to induction of labour in the treatment of contracted pelvis or of the toxæmias of pregnancy. Twelve out of thirteen infants were born spontaneously with the occiput in the posterior position. The forceps rate was under 3.5 per cent.
2. The morbidity rate was, it is believed, the lowest recorded by any hospital in this country.
3. The methods used in the labour ward can be carried out in any tenement dwelling in the country, no sterile gowns, towels, masks, or stockings being required.
4. A manoeuvre for estimating whether a head can pass through the pelvis is described.
5. It is suggested that rendering the urine alkaline during the puerperium by administering potassium citrate is of importance in preventing morbidity.
6. A technique for preventing mastitis and breast abscess is given.
7. The value of the prophylactic use of anti-streptococcal serum is stressed.
8. It is suggested that the maternal mortality would be lessened if midwives were not allowed to make vaginal examinations.
9. It is further suggested that the increasing maternal mortality rate must be attributed to increased operative intervention. If the present policies are continued a still further increase may be anticipated during this decade.

In conclusion, I desire to record my appreciation of the cordial co-operation afforded by the medical superintendent, Mr. J. Carver, and I should like also to thank his deputy, Dr. N. S. Craig. I am indebted to Miss P. N. Hooper and Miss E. M. Carless, who have done most of the hard work. Last, but not least, my warmest thanks are due to the sisters and nursing staff, and, in particular, the senior sister, Miss G. Williams.

DIPHTHERIA IMMUNIZATION IN A SCHOOL

BY

WILLIAM G. PATTERSON, M.D.ED., M.R.C.P.LOND.,
D.P.H.

MEDICAL OFFICER OF HEALTH FOR WEYBRIDGE

Vaccination against small-pox has the supreme merit that in almost 100 per cent. of cases it develops complete protection against small-pox in a period shorter than the incubation period of the disease. Schick immunization, unfortunately, requires for its development a period greatly in excess of the incubation period of diphtheria. Hence Schick immunization is of itself an imperfect means of eliminating an outbreak of diphtheria without further mortality or morbidity. Greatest stress is therefore correctly laid on the importance of Schick immunization as a prophylactic procedure prior to the appearance of diphtheria in a community. But the value of Schick immunization as a factor in the rapid stamping out of an actual outbreak of diphtheria should not be overlooked.

This communication about an outbreak of diphtheria with which I became concerned in February, 1933, may serve to emphasize the advisability of applying the Schick procedures without delay, in conjunction with other appropriate measures as outlined below, whenever diphtheria appears in a community not previously Schick-immunized. Incidentally, it lays stress on the peculiar virtue of Schick-prophylactic T.A.F. as an efficient immunizing agent characterized by great freedom from undesirable general or local secondary reactions.

The Epidemic Described

The residential school in question had 310 boys, aged from 8 to 16 years. The physical condition of the boys was excellent, and they were extremely well cared for; but unusual facilities for droplet infection existed, owing to the close proximity of the beds in the very large dormitories; moreover, scarlet fever had been endemic in the school for some time. The stage was surely set for a considerable outbreak of diphtheria should the infection be introduced.

The first three cases of diphtheria were notified to me on the afternoon of February 5th, 1933, when N. M. and T. P. were admitted to Ottershaw Isolation Hospital under my care. The third patient, R. S., had died on February 3rd after a short illness; the diagnosis in his case was confirmed by a posthumous report concerning his throat swab, which had been taken just prior to his death. N. M. had a severe attack of faucial diphtheria, from which he made an uneventful recovery. T. P. had an extremely severe attack of diphtheria, from which he made an unexpected recovery.

A possible source of the infection was a fourth pupil, P. T., who, during the subsequent routine examinations, was discovered to have incipient paralysis of his soft palate; he subsequently developed complete paralysis of his soft palate and a severe degree of paresis of the legs; his paralytic complications kept him bed-ridden for several months. P. T., within a few days of his arrival home in London for the Christmas holidays, had developed a "sore throat." The only swab taken was negative for Klebs-Loeffler bacillus, and the diagnosis of diphtheria was not made. As this strong athletic boy was kept in bed at home for three weeks with a "sore throat," it is probable that his undoubted attack of diphtheria was severe from the onset.

Thus of the first four cases of diphtheria at this school one died, one almost died, one developed severe and long-lasting post-diphtheritic paralysis, and the fourth had quite a severe illness. It was obvious that the diphtheria which was presenting itself was of a virulent

nature. Dr. Cooke, the school medical officer, who was more than fully occupied with an epidemic of influenza in his private practice, kindly gave me a free hand to make my own arrangements at the school.

I visited the school on February 6th, and by the next morning had the following measures under way: (a) Schick-testing and immunization, (b) detection and control of carriers, and (c) institution of daily routine examination of pupils to ensure early detection of any new cases of diphtheria.

Institution of Schick-testing

On February 7th and 8th I Schick-tested 310 pupils and twenty-seven members of the staff. Since I proposed to use T.A.F. as the immunizing agent, and had therefore no apprehensions about undesirable secondary reactions, I did not perform any control test with heated toxin, nor did I carry out the Moloney test. This was in accordance with my usual practice, and anyone who agrees that 337 intradermal injections in two consecutive afternoons is a monotonous business may consider the simplification of the test procedure permitted by the subsequent use of T.A.F. as an additional valuable feature of T.A.F. One week after the test injection ninety-seven pupils and fourteen members of the staff were found to be Schick-positive, and were given the first intramuscular injection of 1 c.cm. T.A.F. The second injection of 1 c.cm. T.A.F. was given after a further interval of four weeks. No Schick-negative boy subsequently developed diphtheria.

Owing to pressure of work I did not retest the Schick-positives until October 31st—that is, almost eight months after their second injection of T.A.F.—when eighty-five of the ninety-seven original Schick-positive pupils were retested and with one exception found negative; the one exception gave a faint positive reaction. These results were in harmony with the clinical findings, as none of the original Schick-positives developed diphtheria after they had received two injections of T.A.F.

Detection and Control of Carriers

Dr. Ferguson, county medical officer of health for Surrey, kindly placed at my disposal the services of Miss Draper, the assistant superintendent of health visitors. She examined the noses and throats of all pupils in the school daily for about a fortnight, referring all suspicious cases to me. We discovered sixteen nasal carriers with rhinorrhoea and positive nasal swabs. Virulence tests were not carried out because they would have cost 15s. each, and in the circumstances I would not have modified my treatment of any reputed avirulent carrier.

Swabs were taken only from pupils with suspicious clinical signs. Wholesale swabbing appeared out of the question, as at 3s. per swab a nose-and-throat swab per pupil would have cost over £90; by careful daily clinical examination for a fortnight, combined with judicious swabbing for confirmatory purposes, we at any rate succeeded in detecting the carriers most likely to be the source of massive infection. My own impression is that careful repeated clinical examination outrivals routine bacteriological examination as a method of detecting dangerous diphtheria carriers in a community as much as careful clinical examination outrivals swab examination as a method of diagnosing the illness diphtheria. The sixteen nasal carriers, who were all Schick-negative, were segregated from the other pupils until the Schick-positives had received their course of immunizing injections. They were then released from isolation as soon as their rhinorrhoea had cleared up, no swabs being taken until then, and only one negative swab being required. The majority of the carriers were back at school within six weeks, though two were detained for three months.

The head master was informed that I did not guarantee, and indeed did not expect, that all of these sixteen boys had ceased to be carriers; it was considered that the risk of massive infection from them had, at any rate, been eliminated, and, moreover, that after all the Schick-positives had received a course of immunizing injections it might be advantageous to turn some carriers loose among them to encourage the development of complete herd immunity, even at the expense of an isolated case or two of mild clinical diphtheria.

A Daily Routine Examination

With the object of ensuring early detection of any new case of diphtheria a daily routine examination of all pupils was for the first fortnight included in Miss Draper's search for carriers. Thereafter the daily examination was carried out by the school nursing staff, and was limited to the Schick-positives, who were examined daily for another three months. Dr. Cooke or I was informed immediately of any clinical condition suggestive of diphtheria. In this way there were discovered three cases of faucial diphtheria, H. S., E. S., and A. P., whose illnesses commenced respectively on February 22nd, March 2nd, and March 12th, 1933. All three were Schick-positives who had received the first injection of 1 c.cm. Schick-prophylactic T.A.F. All three had comparatively mild attacks of diphtheria, and made very rapid recoveries. This may be contrasted with the course of the illness of the first four patients, of whom one died, one almost died, one developed severe and long-lasting post-diphtheritic paralysis, and the fourth had quite a severe illness.

While the comparative mildness of the diphtheria exhibited by H. S., E. S., and A. P. was probably due in large part to the relatively early administration of the anti-diphtheritic serum, by clinical impression was that their diphtheria was of a mild nature from the onset. If this clinical impression is correct, possible alternative explanations are that, as a result of the first injection of T.A.F., they had developed either a considerable degree of immunity or facility to develop it rapidly when required, or that, owing to the removal of the frankly clinical diphtheria carriers from the school community, they had received relatively small doses of the diphtheria organisms from missed carriers.

Summary and Conclusions

In this residential school of 310 pupils, with exceptional opportunity for droplet infection in the somewhat crowded dormitories, and a synchronous prevalence of scarlet fever, a threatened epidemic of virulent diphtheria was stamped out within five weeks without further fatality and with very little further morbidity. Three agents were used to secure this result: (a) Schick-testing and immunization, (b) detection and temporary isolation of carriers, and (c) routine daily examination of pupils for new cases over a period of three and a half months.

All three agents played a vital and separate part in securing the good results obtained. The Schick-immunizing agent employed was T.A.F.—two 1 c.cm. injections being given at four weeks' interval. No general or local secondary reactions of any magnitude were observed. From the administrative point of view it should be emphasized that the great virtue of T.A.F. as an immunizing agent is that it seldom causes any undesirable secondary reaction. A diphtheria-immunizing agent capable of producing immunity with one injection and with greater rapidity than T.A.F. is greatly to be desired; but unless such an agent compares favourably with T.A.F. in respect of secondary reactions it should not replace it for general use. We do want a diphtheria-immunizing agent comparable with small-pox vaccination for certainty and

speed, but not at the expense of comparison with vaccination for severity of general and local reaction.

The experience outlined above suggests that Schick-testing and T.A.F. immunization, combined with detection and temporary isolation of carriers and adequate precautions to ensure early detection of new cases of diphtheria, will suffice to stamp out quickly a threatened epidemic of virulent diphtheria without further mortality, with little further diphtheria morbidity, and with no appreciable undesirable secondary reactions, in any community where the necessary administrative procedures can be carried out efficiently. If T.A.F. can do so much it should not be too readily discarded for "one-shot" diphtheria-immunizing agents until, as already stated, one is secured which compares favourably with T.A.F. in regard to absence of undesirable secondary reactions.

UNDULANT FEVER AND CONTAGIOUS ABORTION IN NORTHUMBERLAND

BY

A. I. MESSER, M.A., M.B., CH.B., D.P.H.
BACTERIOLOGIST, NORTHUMBERLAND COUNTY COUNCIL

The results of the examination of a first series of Widal sera for agglutinins to *Br. abortus* were recorded in a previous note (Messer, 1932). The investigation has been continued, and in the past three years sera from 425 patients have been examined: In sixteen (3.7 per cent.) of these a diagnosis of undulant fever was considered justified on serological and clinical grounds, the serum titres being as follows:

1 in 125 ...	2 cases	1 in 1,500 ...	5 cases
1 in 250 ...	1 case	1 in 2,000 ...	2 cases
1 in 1,000 ...	2 cases	1 in 3,000 ...	2 cases

In the remaining two cases complete agglutination occurred in a serum dilution of 1 in 250, but the end-titre was not ascertained; fifty of the sera agglutinated *R. typhosus* and eighty-nine *B. paratyphosus* B in significant titres. The bacterial suspensions used were those supplied by the Oxford Standards Laboratory and the minimum "reduced titre" observed among the sixteen cases of *abortus* infection was 62.5.

Some discussion has centred round the significance of the agglutination reaction in the diagnosis of undulant fever. The consensus of opinion, however, with which the experience here recorded agrees, is that the test has much the same value and limitations as the Widal reaction in enteric infection. Both tests require to be interpreted in the light of what is known of the distribution of antibodies in the population at large, and having regard particularly to the occurrence of agglutinins resulting, in the case of enteric infection, from preventive inoculation, and, in the case of undulant fever, from the latent infections which are especially liable to occur in certain occupational groups. The difficulties thus arising are, however, simplified to some extent by the fact that a majority of active *Brucella* infections are accompanied by antibodies reacting in high dilution—1 in 1,000 or more—and such titres may usually be accepted as diagnostic. Equivocal results can frequently be elucidated by means of repetition of the test at intervals.

Clinical Features

Clinically, the cases that have been met with may be roughly divided into two groups. The first consists of six cases of a more or less mild—even ambulant—type in which the chief symptoms were headache, fatigue, loss of appetite, weakness, and sweating, especially at night.

Although mild, several of these cases ran a prolonged course. The remaining cases constitute a heterogeneous group in which the illness was of a more acute nature with a very varied symptomatology. Among the initial diagnoses tentatively advanced were enteric fever, tuberculosis, gall-stones, and arthritis. Brief notes of some of the more interesting of these are appended.

CASE I

Male, aged 74, clerk in drapery store. Illness began in August, 1931, with loss of appetite, asthenia, and persistent temperature. No other symptoms or physical signs. Temperature ran a curious course, consisting of sharp febrile bouts initiated by a rigor and lasting five or six days, alternating with varying periods of normal temperature, the illness being described as somewhat resembling malarial attacks. Patient became progressively weaker, and the illness terminated in January, 1932, with rigor, delirium, and death. Serum titre against *Br. abortus*, 1 in 3,000 on November 3rd, 1931.

CASE II

Male, aged 44, dairyman. In October, 1931, complained of pain in right hypochondrium and was sent to hospital with diagnosis of gall-stones. After being under observation for a few days was operated on, but nothing was found. Was transferred to a medical ward till temperature settled, but after return home had haemoptysis, and later numbness of left hand, especially middle, ring, and little fingers, with loss of power for gripping. These symptoms gradually disappeared and he was ultimately able to return to work, the total duration of his illness being about twelve months. Serum titre against *Br. abortus* on November 11th, 1931, 1 in 250. The dairy herd with which the patient worked consisted of tuberculin-tested cattle. Specimens of blood were obtained from all the animals in the herd—twenty-eight cows, one bull, and six calves. Of the twenty-eight cows the serum of two agglutinated *Br. abortus* at 1 in 2,500, ten at 1 in 1,000 (four had been vaccinated), two at 1 in 1,500, two at 1 in 250 (one had been vaccinated), three at 1 in 50, and one at 1 in 25; eight were negative. The serum of the bull was negative. Of the six calves the serum of one agglutinated at 1 in 25, one showed a trace only at 1 in 25, and the remaining four were negative.

CASE III

Female, aged 41, housekeeper on a smallholding. Duties included milking. On October 30th, 1932, suddenly seized with acute abdominal pain and sickness and very severe rigor. When seen was collapsed and shivering. Temperature 101° F., pulse rapid and poor. Complained of severe gastric pain. Next day very much better, and by November 4th insisted on commencing work. Seen again on November 17th. Was then looking very miserable and complained of always feeling cold and tired. Temperature 101.6°. Admitted to hospital for observation and nursing. After admission only symptoms were weakness and night sweats, temperature ranging from 97° to 98° in the morning to 102° to 103° at night. Serum titre against *Br. abortus*, 1 in 2,000 on November 23rd, 1932. Four of the six cows which this patient milked were subsequently found to give positive agglutination reactions.

Contamination of Milk Supply

Since attention was first directed to the occurrence of *Br. abortus* infections in this country a number of observers have reported on the extent to which the milk supply is contaminated with this organism. As regards ordinary market milk the percentage of positive samples varies in different circumstances from about 20 to 40, and recent work by Pullinger (1934) indicates that certified and Grade A (T.T.) milks are equally liable to be infected. During 1932-3 a series of milk samples sent to this laboratory for examination for *B. tuberculosis* was also examined for *Br. abortus*. The method adopted was the demonstration of agglutinins in the serum of guinea-pigs inoculated subcutaneously with the deposit obtained by centrifuging 50 c.cm. of the sample for thirty minutes at 3,000 revolutions per minute, the

animals being killed after six weeks. Two animals were used for each test for *B. tuberculosis*, but only one of each pair was examined for *abortus* agglutinins. A serum titre of 1 in 20 or higher was accepted as evidence of infection. Of 720 samples so examined 145 (20.1 per cent.) were positive; thirty of the samples were of Grade A milk, six (20 per cent.) being positive, while the only sample of certified milk included in the series was also positive. In addition, eighteen (23.6 per cent.) of seventy-six samples from individual animals suspected by veterinary officers to be suffering from tuberculosis were found to contain *Br. abortus*.

Pullinger reports that of 105 samples of non-graded milk from herds in Cheshire thirty-nine (37 per cent.) contained *Br. abortus*, while of 104 similar samples from Somerset only twenty (19.2 per cent.) were positive. He suggests that this difference may be largely accounted for by variation in the size of the herds, though the possibility that the incidence of the disease is actually greater in the former county cannot be excluded. The present investigation affords some results bearing on this point which may be of interest. The majority of the samples were collected directly at farms in the county. In 401 instances the number of animals constituting the herd was stated, and the following table shows the proportion of positive samples according to the size of the herd. Smith (1932), who, however, used a more thorough technique and included cultural as well as agglutination tests, has published data on similar lines relative to Aberdeen, and although the size of the herd was stated in terms of the daily supply in gallons, Smith's figures may be modified for purposes of a rough comparison with the present results as shown in the table, if it be assumed that the average yield per cow is two to two and a half gallons per day.

Number of Cows in Herd	Aberdeen *			Northumberland		
	No. of Samples	No. +	% +	No. of Samples	No. +	% +
1-9	58	24	24.4	225	21	10.2
10-19	102	26	25.5	122	24	19.6
20-29	51	19	37.2	49	18	36.7
30 +	28	10	35.7	25	10	40.0
Totals	279	79	28.3	401	73	18.1

* Modified from Smith.

Epidemiological Considerations

From the epidemiological standpoint no wholly satisfactory account of undulant fever appears to be possible as yet. Foreign opinion seems inclined to regard the disease as an occupational one, but the evidence collected by Champneys (1933) strongly suggests that in this country, while a small proportion of cases are due to direct contact with cattle, the majority result from the consumption of infected milk. Other possible sources of infection, such as contact with pigs, sheep, horses, dogs, or the consumption of milk products such as butter, cheese, ice-cream, are probably unimportant (Smith, 1934). There are certain difficulties in the way of accepting milk as the vehicle of infection, the chief being, first, that the number of (clinical) infections appears to be extremely small in proportion to the number of persons who may be presumed to be at risk, and secondly, that the incidence of the disease falls chiefly on adult males. By way of explanation of the paucity of cases it is suggested that a process of latent immunization takes place analogous to that known or conjectured to occur in other infections, and the age and sex incidence is accounted for

on the supposition that women and children are larger consumers of milk than men and consequently form a more highly immunized group in the community.

This hypothesis, however, itself creates a difficulty, since naturally acquired immunity postulates contact with the infecting agent, and clinical disease may be expected to occur most frequently among those undergoing the immunization process—that is, as regards undulant fever, those having close contact with cattle and those most accustomed to drink milk, presumably children. It has been demonstrated that latent *abortus* infections are much most frequent in the occupation group mentioned than in the population as a whole (Wilson, 1932), and there is some reason to suppose that clinical disease occurs among them more frequently than the recorded incidence would suggest. In this respect, therefore, the hypothesis outlined may not be greatly at variance with the facts. But among children both latent infection and clinical disease are apparently very uncommon, a remarkable circumstance having regard to the known incidence of *abortus* infection of milk. It is possible that the disease manifests itself in a somewhat different manner in children, and in them a mild febrile disturbance is perhaps more likely to escape adequate investigation, its real nature remaining undiscovered. On the other hand the validity of the assumption that children are in fact large consumers of milk may be worth reconsideration. Inquiries such as those of Savage (1926), Gellatly (1933), and Burns (1933) in Somerset, Cambridgeshire, and Durham respectively suggest that the use of milk as a beverage in this country is decidedly rare. One wonders, indeed, whether the

drinking of milk, so far from being common among children, is not rather a habit acquired by adults, and one is led to speculate on the results which may follow the contemplated widespread distribution of raw milk in schools.

It has been suggested that the virulence of *Br. abortus* for man is being gradually increased by animal passage, and that ultimately case-to-case infection may follow and a fresh public health problem arise. Contagious abortion of cattle, however, appears to be a disease of some antiquity. Hull (1930) states that it was recorded by Moscall as long ago as 1567, and quotes from *The Complete Farmer* of 1807 instructions for dealing with infected animals. Any abrupt exaltation of virulence at this stage appears unlikely, but it does seem possible that the virulence of the *Brucellae* may be maintained through the exchange of strains between different animal species.

I desire to express my thanks to Drs. J. C. Yeoman, R. L. Dagger, and J. C. Mackay for permission to publish the clinical notes of their cases, and to Professor T. J. Mackie for advice and criticism in preparing this memorandum for publication.

PROGNOSIS OF HAEMATEMESIS

A STATISTICAL REVIEW

BY

T. A. LLOYD DAVIES, M.D., M.R.C.P.LOND.

MEDICAL REGISTRAR, ST. THOMAS'S HOSPITAL

AND

R. W. NEVIN, M.B.CANTAB., F.R.C.S.ENG.

SURGICAL REGISTRAR, ST. THOMAS'S HOSPITAL

When considering the prognosis of any disease it is necessary to carry out a statistical investigation of a large number of cases of the condition. In the case of haematemesis this has been done frequently with conflicting results.

Hurst¹ (1928) gives a mortality of 2.5 per cent. among cases of haematemesis following peptic ulcers at Guy's Hospital, and suggests that the stomach should be washed out with ice-cold water. At the Bellevue Hospital, New York, Hinton² (1931) found a mortality of 20 per cent. among fifty-two cases of gross haemorrhage. Gordon-Taylor³ (1934) states that at the Middlesex Hospital the total mortality of haematemesis following peptic ulcers treated medically was 24 per cent., and that the mortality in those cases in which a second large haemorrhage occurred was 78 per cent. Aitken¹ (1934) divided the cases of haematemesis at the London Hospital into two groups—moderate and severe. The total mortality of both groups was 11 per cent. Most of the moderate cases recovered, whereas twenty-seven out of sixty-three severe cases died (43 per cent.). Meulengracht⁴ (1933) has recently treated 119 cases with a liberal diet immediately after the haematemesis: there were only two deaths in this series. This appears to be an entirely new method of treatment, the value of which it is difficult to assess. Chiesman⁵ (1932), at St. Thomas's Hospital, reviewed 191 cases of haematemesis and gross melaena following peptic ulcers (occurring during the period 1925 to 1931 inclusive). The total mortality was 27 per cent., but in cases in which the haemorrhage was continued or repeated within twenty-four hours after commencement of treatment a mortality of 74

per cent. was shown. He did not distinguish between the severity of the different cases.

Cases Analysed

We have made a complete analysis of those cases which were admitted to St. Thomas's Hospital during the years 1924 to 1933 inclusive on account of, or with a history of, significant haematemesis or gross melaena occurring within fourteen days before admission, and also of those cases which developed significant haematemesis or gross melaena in hospital.

By significant haematemesis or gross melaena we mean that which is the obvious result of acute bleeding into the intestinal tract, thereby excluding a large number of cases which vomited small quantities of blood or had slight melaena. We have not divided the cases into aetiological groups, because of the difficulty of deciding the cause immediately following admission, and because even on discharge the cause is not proved in a number of cases. This difficulty is emphasized by Shaw⁶ (1933), who referred to Gutman's⁷ figures, in which in 21 per cent. of the cases no cause could be found.

We have divided the cases into two groups, according to their condition on admission to hospital, or (in the few cases which bled in hospital) immediately after the occurrence. Post-operative cases were excluded.

Group 1. Severe.—The cases whose clinical condition led one to suppose that the haemorrhage was severe, or those in which the examination of the blood showed the haemoglobin to be below 20 per cent.

Group 2. Moderate.—The cases whose clinical condition was not grave, or in which the haemoglobin was above 20 per cent.

By employing a strict definition and subdivision of haematemesis and melaena we have excluded a large number of cases which vomited up small quantities of blood or had slight melaena. Further, a number of cases have been placed in the moderate group which, with

Number and Type of Case	Total Mortality		Repeated Haematemesis			Treatment								
						Medical			Transfusion			Surgery		
	Number of Deaths	Per cent.	Number of Cases	Mortality		Number of Cases	Mortality		Number of Cases	Mortality				
				No.	Percent.		No.	Percent.		No.	Percent.			
Severe ... 153	69	45.1	78	49	61.5	125	55	44.0	26	13	50.0	2	1	50.0
Moderate ... 238	15	6.3	23	7	25.0	223	10	4.9	11	1	9.1	4	4	100.0
Total ... 391	84	21.5	105	56	52.8	348	65	18.7	37	14	37.8	6	5	83.3

a less strict subdivision, might have been included with the severe cases. It is obvious, therefore, that the total mortality, as well as that of both groups, has been raised by this strict definition. Five cases were discarded owing to death from incidental disease, leaving 391 cases, of which 153 were severe and 238 were moderate. The total mortality was 21.5 per cent. (eighty-four cases), composed of severe cases, 45.1 per cent. (sixty-nine deaths), and moderate cases, 6.3 per cent. (fifteen deaths). In cases of repeated haematemesis—that is, cases which suffered more than one large haematemesis before or after commencement of treatment—the total mortality was 52.8 per cent. (fifty-six deaths among 106 cases), the severe cases showing a mortality of 61.5 per cent. and the moderate cases 25 per cent. The results are shown clearly in the accompanying table.

Result of Treatment

The effect of treatment is difficult to assess. All cases received medical treatment (rest in bed, morphine, rectal salines, and nothing by mouth): 348 cases received no additional treatment, and showed a total mortality of 18.7 per cent., severe cases (125) giving a 44 per cent. mortality and moderate ones (223) 4.9 per cent. Transfusion was performed in thirty-seven instances, with a total mortality of 37.8 per cent.; of these twenty-six were severe and showed a mortality of 50 per cent., and eleven were moderate and showed a mortality of 9.1 per cent.

Surgery was employed in an attempt to control the bleeding in only six cases, five of which died. In the successful case a posterior gastro-enterostomy was performed. There was marked pyloric obstruction in this case, in addition to haematemesis. Of the five fatal cases two were treated by transfusion and infolding of the ulcer; one by transfusion, infolding of the ulcer, and ligation of the coronary artery; one by transfusion and partial gastrectomy; and one by laparotomy and transfusion only—no ulcer was found.

The cases receiving surgical treatment are so few that useful deductions cannot be drawn.

Conclusion

1. In this large series of consecutive cases a strict definition of haematemesis and gross melaena is employed, and it appears that the total mortality from significant haematemesis and gross melaena is 21.5 per cent. This corresponds to Chiesman's and other recent figures, but differs from the earlier statistics.

2. The cases suffering from repeated haematemesis showed a mortality of 52.8 per cent., which is approximately the same as the severe cases.

3. The subdivision of cases into severe and moderate appears to be of value. In severe cases the mortality is approximately 50 per cent., whether treated medically with or without transfusion. In moderate cases treated medically the total mortality is 4.9 per cent. Most of

the cases receiving transfusion had "repeated haematemesis," thus accounting for the increase in mortality (9.1 per cent.).

We are indebted to the staff of St. Thomas's Hospital for permission to examine the records of the cases admitted under their care, and particularly to Dr. H. L. Tidy for his interest and encouragement.

Clinical Memoranda

TUBERCULOUS MENINGITIS WITH RECOVERY

I think the accompanying report of a case of tuberculous meningitis with recovery may be of interest.

On June 19th, 1930, I was called to see a girl of 14, a boarder in a public school. She complained of a sore throat; her temperature was 102.6° F., and her general condition was good. On account of the appearance of the throat I took swabs on two successive days, but they were negative for diphtheria. The throat quickly cleared up, and by the 24th the patient said she felt quite well. Her temperature remained about 99.4°. Examination failed to reveal any other septic focus or any tuberculous focus.

On the morning of the 25th, and after a peaceful night, the patient awakened about 4.30 with severe headache. I saw her at 10.30 a.m., when there was no improvement in the headache, and there was a marked ptosis, especially left, which increased during the day. The pupils were equal, reacting, and slightly dilated, and all reflexes were normal. By the evening the left knee-jerk was very sluggish, the plantar reflex was flexor, and Kernig's sign was negative; there was no head retraction, but there was pain at the back of the head and neck when bending the head forward. During the day she lay motionless, and only spoke when spoken to, or to ask for drinks. Her temperature rose to 102°, her pulse was good, and her respirations were quiet and normal.

By the evening of the following day the patient was semi-comatose. The knee-jerks had disappeared; the plantar reflexes were probably flexor, but doubtful; and Kernig's sign was positive both sides. There was stiffness and pain in the back of the neck, severe ptosis, and the headache was extreme; there was also some earache. In view of this last symptom, and especially as the condition followed immediately upon a septic throat, I called in a consultant ear and throat surgeon for an opinion as to whether the meningitis was aurial in origin, but he reported that the ears were normal.

At 10 p.m. a lumbar puncture revealed cerebro-spinal fluid under great pressure and clear, and immediately after its withdrawal the patient became more comfortable and alert

and spoke intelligently. Thanks to the kindness of Dr. Parry Morgan, who examined the fluid at 11 p.m., it was found that the cell count was increased, that lymphocytes were in excess, and also that there was an excess of globulin. He expressed the opinion that it was almost certainly tuberculous, and this was confirmed the following morning by the finding of tubercle bacilli in the clot which formed. By this time the patient was definitely better, the temperature had dropped, the headache was less severe, and the ptosis not so marked; there was no change in the reflexes, and she was fairly alert.

From then on there was steady improvement, and a week later the knee-jerks were present both sides, Kernig's sign was lessening, there was no headache, no neck stiffness, and she felt well. The pulse rate, which had fallen to 40 per minute, was slowly and steadily rising. At the end of four weeks from the onset of meningitis she was taken home, and at that time her temperature and pulse were subnormal, her knee-jerks were sluggish, and Kernig's sign had not absolutely disappeared. She felt quite well, but easily became excited, and so was advised to remain quietly in bed for a few more weeks.

Repeated inquiries as to her health since then have always brought satisfactory answers, and recently I sent for her to satisfy myself that her recovery was really complete after an interval of four years. I found her more healthy-looking than before her illness, and quite normal in every way. She never suffered from headache, but had not returned to school after the twelve months' holiday I had prescribed.

Cardiff.

CONSTANCE L. PARRY, M.B., CH.B.

RUPTURE OF THE SIGMOID FROM COMPRESSED AIR

This case is recorded to call attention to the great danger of careless or thoughtless handling of the compressed-air apparatus which is now being used in factories and workshops to an increasing extent for the purpose of cleaning by driving sawdust or dirt out of inaccessible corners. The air is driven through a pipe ending in a nozzle at a pressure of 100 lb. to the square inch, and if the nozzle is held within a few inches of the anus the sphincters are not sufficient to prevent the air from entering the rectum. The rectum itself, probably due to its fixation as well as to its thicker muscular wall, always, it would seem, escapes, but the sigmoid flexure is liable to rupture.

As a rule the accident happens as the result of practical joking. A few cases only have occurred in this country, but more have been reported from America, where Block and Weissman, in 1926, collected twenty-seven cases, of which no fewer than nineteen proved fatal. They consider that immediate operation, within two hours at the outside, gives the only possible chance.

The case now reported, that of a man aged 26, did not arise from practical joking, but from misapplied ingenuity in using the apparatus as a clothes brush. He stated that the nozzle just touched the buttocks, and he felt the air enter the bowels. Pain was immediate, and very severe, but he was able to get home with help, and was sent to the Southampton Hospital the next day. His general condition on arrival was quite good, but there was tenderness and slight rigidity in the left iliac fossa, where a thickened sigmoid was palpable. At the operation a quantity of blood-stained fluid was found in the pelvis, and the whole pelvic colon and mesocolon were thickened with oedema and effusion of blood. Fortunately there was no complete rupture, but in five or six places the outer coat of the bowel had given way, exposing the sub-mucosa bulging through the rent. The largest area was about two inches in length, the others being one-half to one inch; the whole sigmoid loop was affected. No lesions were found in the rectum or descending colon. Recovery was rapid and uneventful.

Honorary Surgeon, Royal South Hants and
Southampton Hospital.

Reviews

THE ARCHITECTURE OF PHYSIOLOGICAL FUNCTION

It used to be said of biology that it could hardly be regarded as a science until biological observations were expressed in precise numerical form. The accuracy and delicacy of measurements which abound in current physiological literature have rendered the contention at least obsolescent. The reluctance to admit physiology to the group of exact sciences is now based on different grounds, which may perhaps be indicated by the complaint that no generalizations of such wide application that they could fairly be called natural laws have yet emerged. There is, of course, no question that the wider generalizations of physiology cannot as yet profitably be formulated in mathematical terms; but Professor BARCROFT has shown in a new and important contribution to his subject¹ that such generalizations are gradually crystallizing, and that their range of application in different fields is much more extensive than even most physiologists would have supposed.

Progress in the detailed knowledge of physiological processes is bewilderingly rapid. A new physical or chemical technique and an appropriate animal preparation happen to appear together, first in the mind and then in the laboratory of a physiologist, and a new group of problems is launched. A small band of workers assails the problems, while the rest of the physiological world regards its work with admiration and sympathy but hardly with understanding. Specialization has developed to a point where, but for this book, one might have feared that no one man could appreciate the kernel of the problems fashionable in more than a few of the many branches of physiology.

Professor Barcroft shakes himself clear of the deluge of impersonal reports on what new methods can tell us about bits of animals, and wonders what are the things it would be really interesting to know about in connexion with how the body and its components work. The sort of thing that interests him is the astonishing constancy of certain fundamental properties of an organism, despite the spectacular changes continually proceeding, changes such as the intake of oxygen and food and the output of heat and work. He surveys the mechanisms which contribute to the maintenance of this physiological equilibrium, and finds that they fall into fairly definite classes. Starting, for example, with the processes in the blood, the kidney, and the respiratory apparatus, which ensure an almost unchanging hydrogen-ion concentration, the principles governing the mechanisms which ensure the steady state are formulated. They include adaptations of two kinds, evasion and correction, the principles of maximum activity, and of duplication of mechanism, and so on.

Overriding the significance of any particular class of adaptation, is the consideration that the reaction of an organism to a change almost invariably involves the interaction of a large number of mechanisms. The notion of a single cause, which was serviceable in the early history of the physical sciences, is peculiarly inappropriate in biology. One of the most-needed developments in the theory of physiology, a development which is hardly yet in sight, would be the discovery of the laws governing the integration of the elementary responses of the different mechanisms which co-operate in a single adaptation. Till such laws have been formulated in logical terms, the

¹ *Features in the Architecture of Physiological Function*. By Joseph Barcroft, CBE, M.A., F.R.S. London: Cambridge University Press, 1934. Pp. 278, 106 figures. 2s. 6d.

influence of the teleological argument will persist, owing to its indisputable success as a guide in research; and physiology will remain a little more of an art and a little less of a science than is entirely comfortable for the intellectual integrity of those that pursue it.

But to describe the book as a philosophical treatise would be to convey quite a false impression. For into the somewhat slender analytical framework is built a critical review of the more significant of the current trends of physiological discoveries. The enunciation of principles leads immediately to a discussion of the interpretation of experiments; the reader is put in possession of the leading facts, and feels he is invited to discuss with the author the merits of the case, much as if he were present in the laboratory. The mastery with which this extremely attractive technique of presentation is carried out is only possible because the author has had vivid personal experience in so surprisingly many fields, and has amplified it by a quite unusual insight into what his colleagues in his own and other laboratories are doing and thinking.

To the physiologist the book is a joy for its novel points of view, its innumerable happy ways of expressing them, and the vitality of constructive and critical thought; for anyone who has forgotten nearly but not quite all his physiology there is no book which will so surely revive his interest in it, and bring up to date his information about most of those branches of the subject which, for the moment, seem to matter.

PHYSICAL DIAGNOSIS

Diagnosis and treatment are the two essential parts of the practice of medicine. The treatment to be adopted—that is, the *raison d'être* of medicine—depends on the diagnosis. Diagnosis, therefore, should inform us how to act; it should search out the underlying causes of the disease and so give indications for sound therapy. A discussion of the methods to be used in diagnosis and the deductions to be drawn from the observations made is the subject of several good books, which, from the nature and bulk of the matter to be discussed, are necessarily large. Of this class perhaps the best known and most widely used in British schools of medicine is the book on diagnostic methods by Hutchison and Rainey, the popularity and value of which are attested by the demand for edition after edition. Books which deal mainly with the physical signs of disease that may be elicited by simple means, and which leave out discussion of elaborate instrumental (x-ray, etc.) or biochemical methods are, however, neither numerous nor popular. And this is understandable; since the knowledge of physical signs, especially those elicited by means of the established methods of visual, tactile, or auditory investigation, is best gained in tutorial classes at the bedside. Nevertheless, the student is grateful to have a good summary of what he has learned which he may refer to and study at leisure, and this he will find in a well-written and handy book² by Professor Buck, who is an instructor in physical diagnosis at his own medical school in Boston. The subject-matter covers not only the ordinary ground of the physical signs of the chest, but also those in the head, neck, abdomen, and extremities.

After an introductory section on methods of examination and forms for case records, the author has a commendable chapter on the deductions to be drawn from observation of the patient as a whole. As he says, a good deal can be learned of the personality of the patient from his expression, manner of speech, dress, and actions. And

these observations are not in any sense irrelevant. Not only are a third of the patients who consult the average physician sufferers from personality disorders, but even the symptoms of peptic ulcer and their treatment depend quite as much on the person who has them as upon "the mechanical and chemical physiopathology concerned." A sound description of the physical signs of disease and their interpretation follows. The book will be useful to students beginning their clinical studies, and to teachers of physical diagnostic methods.

HUMAN WORM DISEASES

The earliest concrete theories of disease in man recognized that the worm parasites were among the chief causal agents, but the work of Pasteur and the development of bacteriology relegated the worm theory of disease to an insignificant position. Manson and his school, however, rediscovered the important part helminths play in tropical pathology, and the discoveries made in that field have again directed attention to parasites in temperate lands. Nowadays it is fully realized that, although the bacterial and virus diseases are of major importance in human medicine in Northern Europe, helminths play a distinct, although minor, part in medicine. These are more important on the Continent than in the British Isles, and it is therefore appropriate that the first textbook dealing with human worm diseases should be published in Germany.³ This is essentially a textbook for the physician rather than for the specialist, and it covers all aspects of the subject. An introductory section deals with general principles of parasitic diseases, methods of diagnosis, and general therapy. The major part of the volume considers the individual parasites which are known to occur in man in north temperate lands. It begins with a systematic table of all the helminths recorded from all parts of the world—there are 124 of them—in which the twenty-four treated subsequently in the book are printed in heavier type. Of these, the great majority are parasites of lower animals which are only accidentally found in human beings; many of these are absent from Great Britain and Ireland. In each case the authors discuss morphology, life-cycle, methods of infection and invasion, clinical symptoms and pathology, therapeutics and prophylaxis. Each section concludes with an adequate bibliography. The book is well illustrated with 156 half-tone photographs and drawings, and is printed on glazed paper. It is accurately written, and forms a most useful contribution to our medical libraries.

SURGICAL ANATOMY

The output of textbooks on surgical anatomy, as compared with those on pathology, is very limited, especially as regards works dealing with the subject with any considerable degree of completeness. Among the latter kind may be included the *Surgical Anatomy* of Professor C. LATIMER CALLANDER, which was published last year.⁴ Although the author expressly states that the work is intended to be explanatory and utilitarian rather than encyclopaedic, it has taken ten years in the preparation, and its eleven hundred quarto pages contain a tolerably complete presentation of the subject. It aims at meeting the demands of the practitioner confronting everyday surgical problems. This requires a knowledge of the regional anatomy of the whole body. The primary

³ *Leitfaden der einheimischen Wurmkrankheiten des Menschen*. Von L. Szidat und R. Wigand. Leipzig: G. Thieme. 1934. (Pp. 212; 156 figures. M. 15.50; geb., M. 17.50.)

⁴ *Surgical Anatomy*. By C. Latimer Callander, A.B., M.D., F.A.C.S. With a foreword by Dean Lewis, M.D., Sc.D., LL.D., F.A.C.S. Philadelphia and London: W. B. Saunders Company. (Pp. 1,115; 1,280 figures. 63s. net.)

² *The Essentials of Physical Diagnosis*. By Robert W. Buck, M.D. Philadelphia and London: W. B. Saunders Company. 1934. (Pp. 259; 21 figures. 12s. 6d. net.)

consideration is therefore a satisfactory classification of the entire body into suitable regions, first in relation to the surface and secondly in relation to the body cavities and their contents. The classification varies somewhat in different textbooks; that chosen by the author is thoroughly practical and well adapted for the topographical description of the anatomical surgical approaches, the paths of extension of pathological processes, and the steps of the commoner operations. In addition, special relationships are considered, such as that of the lymphatic channels in relation to their central connexions and to the lymph glands, the relations of muscles to bones explanatory of the displacement of fragments after fractures, and of ligaments to joints in relation to the reduction of dislocations. Further, embryology is to some extent called for in explanation of surgical malformations, and is of special importance as regards the gastro-intestinal tract and peritoneum, the development of which is described at great length and explained with the aid of numerous illustrations.

As to the general plan pursued by the author, the anatomy of the region or organ is first described, and then, under the separate heading of "surgical considerations," the surgical application is fully discussed and the commoner pathological processes liable to occur in the region described. The volume is illustrated by a large number of well-chosen figures, completely explanatory of the text, and there is no doubt the work will take its place as a standard on the subject. The opinion is expressed in the preface by Professor Dean Lewis that as anatomy has come to be regarded more and more as an abstract science its direct application to medicine and surgery has been neglected. In the medical schools the surgical department should therefore hold itself responsible for the proper approach to gross anatomy, and as early as the second year should attempt to develop an interest in anatomy which has a direct application in the clinic.

UNMASKING THE MYSTIC EAST

Lieut.-Colonel R. H. ELLIOT, diverging from his accustomed paths of ophthalmology, has published an interesting volume on *The Myth of the Mystic East*.⁵ Some of the chapters have previously appeared, but others, on snakes and snake-bites, on witchcraft and the notorious Indian rope trick, afford entertaining reading. As the title of the book suggests, the author, by rigorous and rational investigation, is led to conclude that there is no such thing as "the mystery of the East," that fiction and fable have been built up on "the uncritical acceptance of popular superstitions." He thus dismisses "the rope trick," and with the knowledge of an expert conjuror and the eye of a detective he either explains on rational grounds or rejects as clever trickery sword-swallowing, well-jumping, fire-walking, and snake-charming. In many instances much suffering is no doubt endured or ignored by the devotees of some religious cult. Colonel Elliot is richly endowed with what Heine called "the instinct of distrust," and under his sceptical scrutiny witchcraft, occultism, and sorcery are exploded or reduced to rational explanation. The chapters on snakes are full of interest, and are based on years of experience, dating from the author's early co-operation with Professor Fraser of Edinburgh. He regards the dreaded cobra as a gentle reptile unless frightened or irritated; he considers permanganate of potash an unreliable antidote to venom, and looks to specific antivenenes as the most hopeful treatment against infection from snake-bites. In a chapter on the mongoose

and the cobra, Colonel Elliot describes in a dramatic fashion the manner in which the former succeeds in attack on the hooded snake, and attributes the relative security of the mongoose against cobra venom to its skill, alike in onslaught and defence, rather than to any inherited or acquired immunity.

Notes on Books

To the writing of diabetic manuals and primers there is no end, and two new editions have just appeared from two American clinics. From the Mayo Clinic Dr. R. M. WILDER has now reached a fifth edition of his *Primer for Diabetic Patients*.⁶ It covers all the usual ground—diet, special recipes, insulin, urine tests, etc. With slight differences one might be reading Joslin's manual all over again. To refer the reader to Bulletin 28, United States Department of Agriculture (1898), is archaic. From the Cleveland Clinic Dr. HENRY JOHN has produced an extended and revised edition of his *Diabetic Manual*.⁷ It is comprehensive and sound, and, as the author's personality stamps its mark on every page, interesting to the doctor as well as useful to the patient. Dr. John answers the question of "cures" with a straightforward negative, and gives his own views on the diabetic child and wife. We feel that mention should have been made of insulin 80 units per c.cm. (most useful to patients on large doses). And surely the diagram on page 93, which shows orange to contain more carbohydrate than potato, is inaccurate, and should be adjusted. But these are minor criticisms of an interesting and helpful book.

Principal Drugs and their Uses,⁸ by A. L. MORTON, is a pocket dictionary of drugs written for the benefit of nurses, which gives notes on the nature and uses of all the important drugs. The object of the book is to provide elementary information regarding the medicaments in common use, and it seems very well designed for this purpose.

A little book on nursing, under the title "Elementary Précis of the Care of the Sick, Wounded, and of Infants," has been issued in France by the Red Cross Association. Dr. E. K. CONTE has done his work, in compiling this manual, extremely well, and maintains throughout a very practical outlook. The major difficulty of teaching practical work in a theoretical manner has been largely surmounted by a series of excellent line illustrations.

Newnes's *Chemistry in Commerce* is a work for students and practical chemists, to be completed in about thirty-two weekly parts at 1s. each, under the general editorship of Mr. Edward Molloy, with Mr. M. D. Curwen as advisory editor. The first part includes an article on the chemistry and pharmacy of vegetable drugs by Mr. Noel Allport, assistant analyst to British Drug Houses, Ltd., and a short account of first control tests on milk and milk products.

On September 10th, 1932, we printed a notice of Sir JOHN LYNN-THOMAS's pamphlet *Key of All Wales*, in which he set forth the grounds for his belief that Levantine tribes had once occupied the estuary of the River Teifi in Cardiganshire. He has now published a sequel, and copies of this second pamphlet may be obtained from the office of the *Western Mail and Echo* Cardiff (price 1s.). Sir John holds that the discoveries he has made around his home are of great archaeological importance; but he has so far failed to convince the "present holders of the three ring-fences surrounding our Ancient Monuments" that his graven stones, Irish elk bone, triple landing stage, etc., prove a Phœnician occupation of the area between 1500 and 1000 B.C.

SATURDAY, NOVEMBER 10th, 1934

POLIOMYELITIS

The recent epidemic of poliomyelitis in Denmark has again drawn attention to the measures available in the prevention and treatment of this disease. Prophylactic antiviral serum prepared from the horse has already been sent by the Lister Institute to Professor Madsen in Copenhagen, and it is hoped that some facts of statistical value may be obtained as a result. The subject of convalescent serum continues to be a thorny one, and doubts as to its efficacy in treatment seem, on the whole, to have increased with its continued use. These have been emphasized by the therapeutic experiences of Park,¹ the critical analysis of Walshe,² and the excellent statistical survey of Harmon.³

There now seems to be general agreement that the causal agent of poliomyelitis is a virus gaining access through the nasopharynx and undergoing an axonal transmission. Faber and Gebhardt⁴ have, in fact, experimentally traced the course of the virus, after intranasal inoculation, from the olfactory bulb to the cells of the spinal cord, and the first-named author has shown that the symptomatology in man can be explained on the hypothesis of a primary nervous infection. Toomey,⁵ contending that early intestinal and vesical disturbances are due to peripheral paralysis of bowel and bladder, has recently revived the conception of infection of the central nervous system from the gastro-intestinal tract along axons of the sympathetic system. Seeking to prove the contention experimentally, he states that injection of virus into a clamped segment of the bowel produces poliomyelitis in the monkey, and that the development of the disease produced by inoculation of virus is accelerated by the addition of faecal filtrates. Much further work will, however, be needed to assess the value of these observations. Virus has not been isolated from the blood stream in man, and only rarely, and after massive injections, in monkeys. According to this view the three classical stages—systemic infection, meningeal irritation, and paralysis—have no pathological basis, and the separation of abortive and non-paralysed cases is without justification. The possibility must, however, be admitted that the interpretation of the experimental disease in monkeys may not be allowable in judging the disease as it affects man. Martin⁶ argues that a stage of general invasion running parallel to, but having

varying time relations with, the nervous infection does exist in man, and by discarding cerebral and ataxic forms of the disease he simplifies its classical equation into spinal, brain-stem, and abortive types.

Since Levaditi and Landsteiner first showed that the serum of monkeys convalescent from the disease neutralized virus *in vitro* the history of the rationale and development of serum therapy has often been recapitulated in these columns. The only hope of treatment consists in bringing viricidal substances in sufficient concentration into contact with virus before cellular destruction occurs, but if virus is already within the neurones it would appear to be beyond the reach of immune substances. Harmon⁷ concludes from his analysis of a large number of collected case records that treatment with serum has no influence upon the outcome in preparalytic cases. He demonstrates that there is little difference in the incidence of non-paralytic poliomyelitis in untreated and treated preparalytic cases (71.5 per cent. and 70.4 per cent. respectively, of 531 and 2,244 cases during the years 1916 to 1931). Tabulating the results of treatment of preparalytic and early paralytic cases with convalescent serum and Rosenow's antistreptococcal serum, he finds no essential difference either in the mortality rate or in the incidence of the same grades of paralysis. Obviously, intravenous administration is the only method which can bring serum into rapid contact with cells, yet Harmon shows by statistics that the issue is unaffected by the route of therapy. Because of the false perspective in which results were viewed, many treatments have been vaunted, but the uniformity of outcome shows the ineffectiveness of each, though marked general improvement and fall of temperature is observed following the administration of serum.

The conclusive therapeutic experiment has yet to be made, and in the light of present knowledge the most fervent humanitarian can scarcely object to the practice of withholding serum from properly chosen controls. It seems likely that more hope lies in the passive immunization of uninfected children; and the reports of Davide⁸ and Park,⁹ who used convalescent serum, and of Brebner,¹⁰ who injected parental whole blood, are very encouraging, though it is of interest to note here that in Philadelphia,¹¹ of 2,255 children treated during an epidemic with convalescent serum or whole blood, twelve developed the disease. Probably a number of these cases were infected before serum was administered. Finally comes the question of active immunization as a method of prophylaxis. Dr. Maurice Brodie¹² recently presented a preliminary report on his experiences with this method to the American Public Health Association. He pointed out that in 1918 Abrahamson and Gerber immunized monkeys by injec-

tion of formalized virus suspension. Having proved the absence of harmful reactions on himself and other volunteers, including Dr. Park, he administered this vaccine to twelve children. Preliminary tests have indicated the production of antibodies, though whether these will protect against natural infection cannot yet be determined.

THE CHANCES OF MORBID INHERITANCE

"Ought I to get married?" "If I get married ought I to have children?" "If I get married and have children what are the chances of their inheriting my disease or a disease which occurs in my family?" These are questions, says Dr. C. P. Blacker, general secretary of the Eugenics Society and editor of a symposium¹ recently issued, which are likely to be addressed to the physician more and more often in the future. It is to meet this need, by setting forth the principles which should govern a genetic prognosis in many different diseases or groups of diseases, that this valuable book has been written. It is composed of eighteen contributions, each by a specialist and acknowledged authority on the subject with which he deals.

In his brief introduction Sir Humphry Rolleston refers to the great fall in the birth rate during the last sixty years as being due to the progressive adoption of the practice of birth control, "chiefly by those qualified and likely to practise birth control, whereas the families in the other category"—that is, the feckless and improvident—"while as large as before, show a much higher survival rate than formerly as a result of the philanthropic care which has been lavished on them so widely. The aim of eugenics is to counteract this recent and racially harmful development of civilization." The aim of this book, however, greatly to its gain, is limited to practical issues and needs, and its arguments and conclusions are based, not on general assumptions of racial degeneration and a conjectured increase of mental and physical defect, but on observed and carefully assembled fact. Eugenic prognoses are especially likely to be sought by those concerned in such conditions as mental disorder and defect, epilepsy, cancer, and tuberculosis, etc., and therefore a greater amount of space is devoted to these subjects than to other and rarer conditions—for example, haemophilia, albinism, amaurotic family idiocy, etc.—in which the modes of hereditary transmission are well known and the results of mating accurately predictable. Professor Ruggles Gates, who has given the main ascertained facts with regard to the inheritance of normal and abnormal conditions in man in his book *Heredity in Man*, provides here in the opening chapter on "Genetic Principles" sufficient for the practical purposes of this work concerning Mendelian inheritance and the applications to man of the main genetic principles. These principles, he says, are highly elastic and apply with

much greater force to some diseases than to others; also, knowledge is still imperfect in many diseases. Therefore advice given by the physician in some cases can only be of a general character. Again, in certain cases outstanding desirable qualities may so outweigh the presence of certain serious inherited defects that in the last resort "it comes to a judgement regarding probabilities and the weight to be attached to particular beneficial or defective qualities." Advice against procreation should be given, he says, only when the perpetuation of serious defects is involved—that is, when the victims would be handing on their burden to later generations.

Conformably with the principles laid down each author in this deeply informative and interesting series first states the problem and its particular difficulties in the morbid processes with which he deals; then discusses the respective roles in each type of disorder played by inheritance on the one hand and environment on the other; the mode of transmission, if known; and, lastly, the principles on which advice to the inquirer should be based. The work is of so wide a compass—embracing the inheritance of nervous and mental diseases and mental defect; inheritable diseases and abnormalities of the eye, ear, skin, kidneys, blood, and vessels; diabetes, tuberculosis, neoplasms, cretinism, etc., each contribution by a master of his subject—that adequate notice of the whole is impossible here. As, however, advice regarding the risks of transmitting mental disorder or mental defect to offspring is so frequently sought and as these are subjects so much to the fore to-day, the two papers by Dr. Aubrey Lewis and Dr. Henry Herd may be specially mentioned as examples both of the careful and unbiased treatment of rather controversial matters and of the reasoned practical advice which distinguishes the whole number of articles. The extreme difficulties in the way of genetic research into the mode of transmission of mental disorders are widely recognized, and in consequence, as the recent Departmental Committee on Sterilization found, there is nothing like certainty or unanimity of opinion in this matter. But, as Dr. Lewis says in his exposition of inheritance of mental disorders, the discovery of Mendelian relations does not matter so much to the physician who has to give a genetic prognosis. "For him empirical means of predicting the mental quality of offspring are more useful than disputable statements about recessive polymerism and the like. For the last few years investigations have been directed more to this practical end, comparable to the work of an insurance actuary; and arguments about the applicability of Mendelian rules are, for the moment, in the background."

This empirical assessment of probabilities, arrived at mainly by the results of mass investigations of non-related but similarly affected families, certainly throws into high relief the "familial" occurrence of certain mental disorders as compared with their occurrence in random samples of the general population. Thus, to take one example out of many, one investigation quoted

¹ *The Chances of Morbid Inheritance*. Edited by C. P. Blacker, M.D. London: H. K. Lewis and Co. Ltd. 1934. (15s.)

(Luxemburger, Schulz) made upon the siblings (brothers and sisters) of one hundred patients with dementia praecox, one hundred with manic-depressive psychosis, a like number with epilepsy, with general paralysis, etc., as against in each category the siblings of the same number of the general population taken at random, showed that the possibility of manic-depressive psychosis is twenty-five times as great as in the general population, of schizophrenia (including dementia praecox) six times as great, and of epilepsy nine times as great. The intensity of inheritance is thus strongest for manic-depressive psychosis, less for dementia praecox and epilepsy, while for general paralysis inheritance is negligible in comparison with environmental factors. In the concluding twelve pages of a notable contribution to the subject Dr. Lewis discusses the application to the individual of the probabilities of occurrence of various mental disorders among the children, siblings, grandchildren, nephews and nieces, and cousins of affected parents so far as these have been thrown up by investigation. His whole exposition is admirable in manner and treatment, and goes far to justify his remark that the last twenty-five years' painstaking work of a few men, foremost among whom is Rüdin, has wiped away the reproach that genetic psychiatry was bad psychiatry and bad genetics. It will be read widely and with much profit; for even if, as Dr. Lewis says, "the physician's eugenic advice is perhaps oftener sought than followed, for loyalty, love, plighted obligation, wilful optimism that is blind, social or economic advantage may in their degree prevail against mere assurances of probability, and assurances of probability are all the physician can offer," it is also true "that it is not to be supposed that he acts only by deprecating: he can also reassure and encourage."

CONTROL OF SECRET REMEDIES

The English are a conservative people, with no love of logic. But though hard to move in matters of sentiment or opinion, and patient almost beyond belief, they have a way of accommodating themselves in double-quick time to a new order once it has been put into force. To illustrate this point we need only mention daylight saving, conscription and food control in wartime, women's suffrage, roundabout traffic, and now the prohibition of the use of motor horns at night in "built-up areas." All these things were said to be impracticable, or worse, and a hundred objections bobbed up beforehand. Yet each proved to be workable, and in the twinkling of an eye the people of this country got accustomed to it. In short, we are a law-abiding race so long as the law is believed to be made in the general interest and appears to touch all alike. The hard task is to get a good measure on to the Statute Book: there is little difficulty in enforcing it. The things that stand between Britain and many long-overdue reforms are the vested interest, the timid or time-serving politician, and the newspaper proprietor with one eye on what big advertisers will do and the other on what he pretends to imagine his readers

will stand. If, for example, the patent medicine business were cleaned up to-morrow and all the worst offenders swept into bankruptcy, there would be no outcry from the poor and ignorant whom the nostrum-monger exploits, but there would be some further unemployment and much loss of advertising revenue. A great deal of dishonest nonsense is talked about "not legislating ahead of public opinion." If reform had always waited upon public opinion we should still be having public executions.

The case for the control of secret remedies is unanswerable. It was put plainly by the British Medical Association in its evidence before the Select Committee on Patent Medicines, and the Select Committee's report, issued as a Blue Book in 1914, was an uncompromising document—which the newspapers ignored. It is true that that report had the bad luck to appear on August 4th; but if there had been no war we take leave to doubt whether the lay Press in general would have given it any publicity, notwithstanding its obvious "news value." One of the first things Dr. Addison did as Minister of Health was to father a Bill based on the Committee's proposals, and Lord Astor introduced it in the summer of 1920. It never reached the Commons. Eleven years later Mr. Somerville Hastings introduced a milder Bill with the support of the Labour Party's advisory committee on public health. This, too, was dropped. Now a still milder measure is under consideration by the Parliamentary Committee on Food and Health—and its mildness may be judged by the fact that the patent medicine trade has agreed to offer no opposition. The Council of the Royal College of Surgeons of England, whose statement on patent medicine legislation we reproduced last week at page 822, has informed the Committee on Scientific Research of the Economic Advisory Council, in answer to an inquiry, that in its opinion the problem can only be adequately dealt with on the lines laid down by the Select Committee of the House of Commons in 1914. This is also the view of the British Medical Association, and was declared to be so by the Annual Representative Meeting in 1915.

INTRINSIC NERVOUS MECHANISM OF THE HUMAN LUNG

Whilst the greater part of our knowledge of the mechanism of respiration has been obtained by physiological experiments, the contributions made by the anatomist and histologist have been the starting-point in many directions. The significance of many physiological experiments becomes either more apparent or more difficult to see according as the results can be correlated with anatomico-histological findings. Anatomical bases for well-known physiological phenomena are still lacking. It is therefore gratifying to see that certain workers are persevering with the finer definition of pulmonary innervation. Such work has recently been published by J. B. Gaylor.¹ The nerves of the lung, derived from the pulmonary plexuses, enter at the hilum and present two separate and distinct

¹ Brain, 1934, lvii, 143.

symptoms—the vagal and the sympathetic. Gaylor divides his observations into those on the bronchial plexus, the epithelial innervation, the nerve endings in the plain muscle of the bronchi and bronchioles, the innervation of the glands, and the pulmonary vessels. The large and middle-sized bronchi are very richly supplied with nerve fibres, and the plexus can be traced far down to the terminal bronchioles. The complexity of the bronchial network and the free intermingling of the fibres lead this author to consider it as one unit, and not as divisible into an intrachondrial and an extrachondrial. Along the course of this plexus are found nodes which may or may not contain ganglion cells, but ganglia may also exist on the course of the nerves at other places than these nodes. So complex is the arrangement of the fibres that it is impossible to trace an individual fibre for any considerable distance. A peculiar fact is that fibres may pass straight through a ganglion without loss of the medullated sheath, whereas others are related to the ganglion as pre- and post-ganglionic fibres. This plexus supplies the bronchial epithelium, the bronchial muscles, and the bronchial glands, and Gaylor considers that the non-medullated fibres have to do with the innervation of the vessels of the bronchial capillary bed. The nerves supplying the bronchial muscles are non-medullated, which appear to be motor in function, and medullated, which appear to be sensory. The latter are without doubt vagal in origin, and impulses derived from stimulation of the endings travel via the bronchial plexus into the main vagal trunk. The sensory endings associated with the plain muscle are found at the junction of the muscle bands. It must be recalled that the bronchial muscle is not a continuous sheet but a network of bands, some running transversely across the bronchus and some obliquely or even parallel to the long axis. This arrangement is such that during contraction of the muscle there will be, in addition to some constriction of the bronchial airway, a definite shortening of the bronchial tree. Now the position of the sensory endings is such that maximal stimulation of them will be produced when the bronchial muscles are stretched and the meshes of the muscular network widened—that is, during inspiration. In support of his contention Gaylor points out that the sensory endings here considered are morphologically of the type found in the carotid sinus, which are specially adapted to respond to stretch, and also that the position of these endings is at points of division of bronchi, where the greatest amount of movement occurs. It is reasonable to regard these sensory endings as sensitive to stretch of the muscles, and further that they are the receptors for the well-known Hering-Breuer reflex. This leads the author to a hypothesis of the mechanism of bronchial asthma. Whereas it is often considered that many of the symptoms of asthma result from stimulation of the endings in the bronchial musculature, Gaylor is disposed to believe that the contraction of these muscles prevents the normal stimuli of stretch to which the afferent endings are susceptible. He suggests that in addition to the mechanical difficulty of expiration in bronchial spasm there is a nervous upset. The relatively greater difficulty in expiration is partly explicable by the fact that the capacity of the chest works against the spasm in inspiration and with it in expiration. The greater inspiratory effort required to

produce an adequate stimulation of the afferents may be such that expiration may become a voluntary act. The author makes certain interesting suggestions as to the significance of collaterals of the vagal afferents in the bronchial wall. As it appears unlikely that a single fibre gives rise to several sensory endings he concludes that they are rather of the nature of "intrinsic pre-ganglionic fibres," and that stimulation of a single sensory ending will, by means of an axon reflex, cause a local capillary response, and, in addition, a more extensive response via the collaterals and the nodal ganglia. Such a mechanism (and it has the merit of being supported by careful histological evidence) would make clearer the widespread effects (for example, secretion of mucus, contraction of the bronchial muscles) which accompany the coughing reflex when a local irritant stimulates the bronchial mucous membrane.

THE SEMON LECTURE

The Semon Lecture for 1934 was delivered on November 1st by Mr. Herbert Tilley. The occasion was exceptional, because it is an open secret that Mr. Tilley was reluctant to accept the lectureship. This reluctance arose in part from the fact that, since the lectureship was established in 1911 during the lifetime of Sir Felix Semon, Mr. Tilley has always taken the chief part in its management, and a natural delicacy restrained him from assuming the mantle of lecturer himself. The unanimous desire of all connected with British laryngology that its most popular personality should not be debarred from the honour of the Semon lectureship has at length induced him to overcome these scruples and to yield to the universal demand. The audience therefore had the double satisfaction of having the lecturer whom above all others it wished to hear on this occasion, and of listening to the wisdom gained from a ripe experience in the subject of which he has made a long and particular study. As the management of the lectureship was entrusted to the University of London, the many services of Mr. Tilley both to the University and to laryngology have received an appropriate recognition, for in addition to his pre-occupation with the Semon lectureship they include a large share of responsibility in the establishment of the M.S. London with laryngology, and of the D.L.O. of the Royal Colleges. Mr. Tilley dealt with his chosen subject from a broad standpoint, but he was careful to stress some aspects which even now do not always receive sufficient recognition. The spread of infection from the antrum is not always by surface transmission, by which direct spread to adjacent tissues is implied, but also by vascular convection, which includes transmission by both lymph and blood vessels. The lecturer illustrated this by radiographs showing spread of infection in this way from the antrum to the tissues of the mediastinum. This chronic catarrh of the antrum is a condition which is not uncommonly overlooked, and its influence may extend to distant parts. Mr. Tilley also laid emphasis on a pathological condition which is often not included in the usual descriptions of the various changes affecting the antrum. When the periosteum becomes implicated the infection passes by vascular channels into the osseous capsule of the sinus. It is, in his opinion, the failure to recognize this condition (which Mr. Tilley was able to demonstrate from

pathological material prepared by Dr. Albert Gray at the Ferens Institute of the Middlesex Hospital) that accounts for many post-operative recurrences and failures to obtain complete healing. A study of the lecture, of which a full report appears at page 869, will show that Mr. Tilley succeeded in extracting much interest and some novelty from an apparently rather threadbare subject.

SNAKE VENOM FOR HAEMOPHILIA

Haemophilia is a condition which causes much misery to patients and their relations, and anything which can be done to relieve it is to be welcomed. The prominent feature in the condition is the time which the blood takes to clot, and the poor quality of the clot which is formed. Hitherto no styptic has proved of any value in stopping the haemorrhage, and it has often been necessary to perform a blood transfusion lest the patient should bleed to death after a trivial injury. The preliminary report of the recent work by Dr. R. G. Macfarlane and Dr. Burgess Barnett¹ suggests that a styptic has been found which may be of great value. It has been known since the work of C. J. Martin in 1893² that when snake venom was injected into animals it might cause extensive intravascular clotting. G. Lamb in 1903³ showed that it would also clot citrated blood. Macfarlane and Burgess Barnett, at the suggestion of Professor H. Hartridge, have now demonstrated that snake venom has a very powerful action on haemophilic blood. They have found that the venoms of all kinds of vipers coagulate blood, but that they differ considerably one from the other in various ways. The venom of Russell's viper clots haemophilic blood more quickly than any other venom, although it is not so efficacious as other venoms in clotting citrated blood. The amount required is very small: one drop of a 1 in 1,000 solution of the venom, when added to ten drops of haemophilic blood, caused clotting in seventeen seconds, and a 1 in 100,000 solution caused clotting in sixty seconds, although the blood itself took thirty-five minutes to clot. The actual clot is tough and firm, and quite unlike that of haemophilic blood clotting by itself. Much work has already been done to enable this discovery to be used for human beings. It has been observed that when the venom is injected into animals in a dilution of 1 in 1,000 it does not cause haemorrhage, oedema, ulceration, or destruction of the tissues. When gauze soaked in venom was applied to a wound no delay in healing occurred, as compared with the control animal. The solution is easily sterilized by filtration through a Berkefeld filter, and does not lose any of its strength in this procedure. The venom maintains its potency unchanged when it is dry, but it soon deteriorates in dilute solution. The tests on human beings, not very numerous as yet, are very striking. In a normal person haemorrhage from a tooth socket and tonsil bed and capillary oozing in an abdominal wound are controlled at once. Three patients with haemophilia have been treated, two for tooth extraction and one for a wound. In each case the haemorrhage stopped at once when the tooth socket and wound were lightly plugged with gauze soaked in

venom 1 in 100,000. The haemorrhage recurred some twelve or twenty-four hours later, but ceased again on a further application. It does not seem likely on the present evidence that the venom will have any effect in reducing the coagulation time to normal and so cure the disease, and it is also doubtful whether it can be employed for checking the haemorrhage into joints and subcutaneous tissues. Nevertheless an important step forward has been taken by the discovery of a substance which will control the local haemorrhage which has caused the death of so many patients. The authors are to be congratulated on their discovery, and it is to be hoped that some way will soon be found of enabling a preparation of venom to be available in all hospitals, and for all doctors who look after haemophilic patients.

VARIATIONS IN THE NORMAL BLOOD COUNT

In an earlier issue this year (March 31st, p. 586) we commented on the findings of R. H. Simpson¹ in a study of the normal blood count. The object of this work was to determine the limits of variation in the normal count in order rightly to assess the significance of early changes in the blood of radiologists. His findings were that the leucocyte count in the normal subject varies within wider limits than are generally recognized, and that these fluctuations apparently follow none of the causes to which they are usually assigned, but occur rapidly and capriciously. The steps taken to verify the accuracy of the method used, including simultaneous counts yielding concordant results, betrayed no inherent liability to error such as would invalidate the conclusions drawn. The only possible deduction from these findings was that the limits of the normal leucocyte count must be set more widely, and that no single count exhibiting minor variations can be credited with any certain significance. In subsequent correspondence this conclusion was contested, and it was suggested that the method used by Simpson for counting the total leucocytes is liable to inaccuracy; in particular, attention was drawn to the work of Ponder, Saslow, and Schweizer,² who studied the relation between the number of cells counted and the reliability of the results obtained. A subsequent publication by Harvey and Hamilton³ lends support to the attitude of these critics. It deals with the results of one hundred counts on each of two subjects, one of whom was normal, the other an asthmatic. These results are analysed and presented in a number of different ways, of which the most illuminating is the ogive graph: this indicates at a glance not only the extreme limits of variation but the frequency of intermediate values. In the strictly normal subject the extremes of the total leucocyte count were 5,500 and 8,500 per c.mm.; and the great majority of the counts fell within narrower limits than this; in the asthmatic the limits were wider, the lower being 7,000 and the upper 15,000 per c.mm. An important fact is that no count fell below 5,500 per c.mm.; a leucopenia determined by these observers would therefore possess a significance denied by Simpson for his own observations. Since it has been stated by Mottram⁴ that a

lymphocyte count of less than 1,500 per c.mm. is a danger signal in radiologists, it is of interest that in Harvey and Hamilton's normal subject this count was below this figure on several occasions; perhaps the limit should be placed lower. In any case the difficulty of interpreting early changes in the blood of radiologists, although distinctly reduced by assuming something nearer constancy in the leucocyte count, is still considerable, and seems to call for repeated counts before serious action is taken. With one of Harvey and Hamilton's conclusions not everyone will agree—namely, that the examination of a film alone can to some extent take the place of a complete count. It is true that a very rough estimate of the total leucocyte count can be made from a well-made film, but the ability to make good films rarely exists without the opportunity and capacity to perform a total count as well, and to countenance this omission seems a retrograde policy.

CHILD GUIDANCE IN LONDON

In the four and a half years of its existence the London Child Guidance Clinic has now dealt with nearly 1,900 cases. In the beginning its organization was largely experimental, but it has now evolved the lines upon which it intends to progress. It was designed from the outset to serve two functions—the treatment of children and the training of students—and early in 1933 it was divided into two separate departments for treatment and training. Each child is treated by a team consisting of a psychiatrist, a psychologist, and two social workers; the same psychiatrist handles each case throughout to ensure continuity of treatment, and the unit members deal directly with the doctor, teacher, or parent referring the case. The course of training includes lectures, discussion groups, and seminars held at the London School of Economics, and supervision of the practical work of the clinic. The report of the clinic for the years 1932 and 1933 states that students who complete this course are being widely accepted for responsible posts where a trained social worker is required, for it is being realized that some such training is necessary to equip workers in psychiatric and child guidance clinics and out-patient departments of hospitals. The clinic also gives candidates for the academic diploma in psychology of the University of London their practical work in child guidance, and supervises and instructs students attending the course in child development at the Institute of Education, who come to the clinic for observation of play groups and for instruction in remedial teaching. The division into two sections has increased the efficiency of both aspects of the work. Members of the clinic have travelled all over England delivering lectures on child guidance, with the result that knowledge and acceptance of the subject have widely increased. The number of children seen at the clinic has steadily grown, and in 1932 an extra psychiatrist and a social worker were appointed. The children have come from all over the British Isles, but the practical difficulties in the way of lodgings near the clinic for regular attendance are great, and satisfactory treatment will be possible for all only when clinics are available throughout the country. During the two years under review the clinic dealt with 973 cases. Children tend to be referred at an increasingly early age—a satisfactory development.

Many are sent from the schools and school care committees of the London County Council, and by magistrates and probation officers. A considerable number of cases attended only for examination, and a large number were given some special type of service, including individual psychotherapy, remedial teaching, or education in play groups. The clinic claims to have secured adjustment in the mentality of about half the children it has treated. About a quarter are discharged partially adjusted, and about one-fifth cannot be improved. These results seem fully to justify the expenditure of time, energy, and ingenuity. The progress of child guidance work in this country has been slower than in some others. This is not altogether a bad thing in an enterprise which is so novel and which is capable of such extremes of theory and experimentation. There is a refreshing absence in the report of the effervescence which is apt abroad to discourage sympathizers with the movement. The clinic shows great promise of success in this important necessity of modern civilization. This particular method of tackling the problems of modern childhood came to us from the other side of the Atlantic, under the auspices of the Commonwealth Fund. The time has now come when that Fund may legitimately say, and does in fact say, that the clinic has either proved its worth or its worthlessness, and that the people of this country must either support it or close it down.

DIXON MEMORIAL LECTURE

Following the death of Walter Ernest Dixon, M.D., F.R.S., of Cambridge in August, 1931, a memorial fund was collected, and the committee thereof, under the chairmanship of Sir William Willcox, handed to the Royal Society of Medicine a capital sum in order to establish a lectureship in therapeutics and pharmacology in memory of Professor Dixon. The first Dixon Memorial Lecture will be given by Sir Henry Dale, M.D., F.R.S., in the Barnes Hall of the Royal Society of Medicine on Tuesday, December 11th, at 5 p.m. The subject of his address will be "Pharmacology and Nerve Endings." No tickets of admission are necessary.

GENERAL MEDICAL COUNCIL ELECTIONS

The result of the election of a direct representative for England and Wales has been that Mr. N. Bishop Harman, F.R.C.S. (with 10,980 votes), has been elected for five years from November 26th, 1934. The unsuccessful candidate, Dr. E. A. Gregg, obtained 3,702 votes. Sir Norman Walker and Dr. Leonard Kidd have been returned unopposed as direct representatives for Scotland and Ireland respectively. We would remind readers once more that voting papers for the election of a second direct representative will be issued on November 13th. Sir Henry Brackenbury has been nominated for re-election. The letter announcing his candidature for re-election was printed in the *Supplement* of October 13th (p. 193). The other nominations received by the Council for this vacancy are Dr. E. A. Gregg and Dr. Mabel L. Ramsay.

The Medical Research Council has appointed Mr. F. J. Marquis, B.Sc., and Professor W. W. Jameson, M.D., F.R.C.P., to fill vacancies in the membership of its Industrial Health Research Board.

CHRONIC PYOGENIC INFLAMMATION OF MAXILLARY ANTRUM AND OTHER ACCESSORY SINUSES

SEMON LECTURE BY MR. HERBERT TILLEY

The Semon Lecture, under the auspices of the University of London, was delivered in the Barnes Hall of the Royal Society of Medicine on November 1st by Mr. Herbert Tilley, M.D., F.R.C.S., consulting surgeon, Ear and Throat Department, University College Hospital, whose subject, illustrated by many lantern slides, was "Chronic pyogenic inflammation of the maxillary antrum and other nasal accessory sinuses: Some clinical manifestations of its pathology." Mr. W. M. Mollison, president of the Laryngological Section of the Royal Society of Medicine, presided.

Mr. Herbert Tilley, after a graceful tribute to the late Sir Felix Semon, by whom, he said, more than by any other one individual, the foundations of the honourable position of British laryngology were truly laid, first reminded his audience of some of the fundamental anatomical features and physiological attributes of the nasal accessory sinuses or air cells. He believed there was no region of the body where normal topographical relationships were subject to such frequent and almost limitless variation as might be presented by these sinuses. They reminded him of the Irishman's definition of bridge as "A game with no rules, but a mighty lot of exceptions." It was this anatomical complexity which frequently determined one or more of the clinical manifestations of an inflamed sinus.

DEFENCE MECHANISMS AND TRANSMISSION OF INFECTION

So far as present knowledge went, the mucous membrane of an accessory sinus had three defensive agents: (1) the thin film of mucus which enmeshed such invaders as atmospheric dust and micro-organisms; (2) the cilia of the epithelium which tirelessly lashed the mucus towards and through the "ostium" into the nasal cavity, from which it was driven by the same mechanism into the nasopharynx; and (3) secretions which found their way to the surface from the glandular nodules and other cells of the stroma. The lecturer dwelt on these factors of mucosal defence, first, because they were the foundations in which alone lay the explanation of the clinical manifestations of inflammation of the nasal cavities and their paranasal air cells, and, secondly, because the occasion afforded him an opportunity of entering a plea for a conservative attitude when surgical measures were called for in the treatment of such a delicate protective mechanism, which in its structure and functions had no counterpart elsewhere in the body.

It was common knowledge that when pyogenic infection had become established in the mucous membrane of an accessory nasal sinus its intrinsic or immediately local signs and symptoms might be accompanied or even overshadowed by evidences of transmission of organisms or their toxins or both to near or remote regions. Further, the clinical manifestations of such dissemination would largely be determined by the channel through which the infective agents reached their destination—namely, "surface transmission," implying progressive involvement of tissues in immediate and direct anatomical continuity with those of the already infected sinus muco-periosteum, or "vascular convection," an expression which he preferred to "blood-borne," because it included the lymph vessels. When the superficial tissues of a sinus muco-periosteum were involved, infection tended to spread by tissue continuity, while a more rigid confinement of sepsis in the deeper layers of the stroma, the periosteum, or in the bone would more probably be conveyed by vascular

ANTRAL INFLAMMATION OF DENTAL ORIGIN

The lecturer went on to describe briefly the course of acute antral inflammation of dental origin. Progressive caries in the crown of a bicuspid or molar tooth eventually reached and infected the contents of its pulp cavity; the consequent inflammation spread to the adjoining root canals, and from these, by way of their apical foramina and root canaliculi, to the periosteum of the root sockets and the cancellous bone of the alveolus in their immediate neighbourhood. In the course of these changes a septic granuloma or apical abscess might develop above the infected root, and by progressive inflammation and absorption of the surrounding cancellous bone reach the mucous membrane lining the alveolar groove of the antrum, ulcerating through, and establishing antral infection. It had long been the lecturer's conviction that extensive pyorrhoea of a tooth socket might alone be responsible for the conveyance of infection by vascular channels to the air cell. For a long time his was a solitary voice in this matter, but later the possibility of vascular transmission of infection from a septic root socket to the antrum had become accepted.

A septic tooth which had slowly become devitalized might infect the antrum without any preliminary acute dental symptoms. It was a good rule, therefore, to have the teeth radiographed in all cases of acute and chronic antral inflammation before deciding the extent to which a dental factor should influence treatment. During dental infection the patient's general condition was often satisfactory, and the lesion in the air cell was limited to ulceration of a comparatively small area of muco-periosteum, through which the abscess contents escaped. The rest of the mucous membrane might only be inflamed superficially, and probably not to such a degree as entirely to inhibit ciliary activity. As a consequence of this, inflammatory secretions passed with comparative freedom into the nasal cavity. Removal of the offending tooth, followed by irrigations of the sinus, would, as a rule, soon restore the tissues to their normal condition. It followed that when symptoms of inflammation developed in and around an upper bicuspid or molar tooth appropriate treatment should be instituted. Prolonged delay might result not only in antral infection, but, what was more important still, in the involvement of a comparatively extensive area of cancellous bone in the alveolus which, in the event of ultimate tooth extraction, would often render futile all efforts to close a possible bucco-antral fistula. In the meantime, general symptoms indicative of a mild chronic toxæmia or some distal and more or less localized manifestation of "focal sepsis" might have developed.

INTRANASAL INFECTION OF THE ANTRUM

If an antrum were infected by the virulent organisms of one of the acute specific fevers the chief pathological features would often be a generalized and intimate inflammation of all the constituents of its muco-periosteal lining and the nasal fossa of the corresponding nasal cavity, more particularly tissues in and around its middle meatus—a condition which hindered free drainage from the sinus. Within the antrum the consequent congestion and oedema might be so pronounced as entirely to obliterate its lumen, and by inhibiting ciliary action add a further hindrance to the escape of inflammatory secretions.

The early stages of infection, when general oedema of the muco-periosteum was pronounced, were manifested by severe pain in the cheek and surrounding regions coupled with nasal obstruction on the same side. An endeavour to relieve these symptoms by puncture irrigation of the antrum would not infrequently fail if the end of the cannula were embedded in the jelly-like mass of inflamed tissues. This difficulty might sometimes be overcome by applying cocaine and adrenaline solutions to the swollen and obstructing tissues of the middle meatus, and then scarifying them freely. Children suffering from an acute specific fever were by no means exempt from infection of the paranasal air cells, but, of course, were often too young to draw attention to, or describe, local symptoms,

and such clinical manifestations of sinus infection as nasal obstruction and muco-purulent discharge from the nostrils were liable to be regarded as due to adenoids.

CHRONIC ANTRAL CATARRH

Mr. Tilley defined this as a low-grade infection of the superficial layers of the mucous membrane accompanied by excessive secretion of mucus or muco-pus, but not by general symptoms of toxæmia or local manifestations of blood-borne infection. In its simplest forms the most characteristic feature was a semi-translucent thickening of the mucous membrane, which was particularly evident over the alveolar groove, in the angular recesses of the air cell, and in the neighbourhood of its "ostium." In more advanced conditions oedema-like swellings or definite polypoid projections were usually present. The chief histological features in the early stages were a certain amount of surface-cell desquamation, extensive serous infiltration of the subepithelial connective tissue, distension of its lymphatic spaces and glandular elements, and perivascular concentration of mononuclear and polynuclear cells. The chief, and often the only, symptoms were an excessive discharge of mucus or muco-pus from the nose and some degree of nasal obstruction. Transillumination was particularly unreliable in diagnosing mild types of chronic antral catarrh, and most misleading if too powerful a lamp was used; puncture irrigation was much more informative, but did not give a clue to the degree of involvement, and here came in the inestimable value of Proetz's "displacement" method, followed by radiography of the opaque fluid. A mild degree of mucous membrane involvement would probably respond to from six to twelve irrigations or even to a course of autogenous vaccines, while polypoid transformation could only be treated successfully by radical intervention through the canine fossa, with the establishment of permanent antro-nasal drainage.

If it seemed that undue attention had been given to this mild type of chronic antral inflammation the lecturer's excuse was that of all forms of sinus infection it was, in his experience, the one most frequently overlooked, because the patient's diagnosis of "chronic nasal or post-nasal catarrh" was too frequently accepted as an entity without further confirmation, but recurrent infections almost inevitably led to definite pyogenic infection of the air cells. In any case the catarrhal symptoms were annoying. Temporary symptomatic relief might be afforded by nasal washes followed by a nebulized oily spray containing menthol or chlorotone. But if valid reasons had been given for regarding such symptoms as typical manifestations of mild infection of the paranasal sinuses, it was obvious that these air cells, and particularly the antra, should be carefully investigated in every case.

PATHOLOGY AND CLINICAL EVIDENCE OF PYOGENIC INFECTION

After some remarks on dietary defects as a predisposing factor in reducing resistance against microbial infection, in which he quoted McCarrison and other authorities, Mr. Tilley turned to a discussion of the pathology, saying that when chronic pyogenic infection had become established in any of the air cells, the histopathology of the muco-periosteum would frequently reveal that the morbid changes were not always uniformly spread throughout the structure, but rather tended to predominate in one or more of its constituent elements. He described the four categories in which le Roy Schall placed the pathological changes—namely, oedematous, infiltrative, fibrotic, and cystic; and to these he himself added a fifth—namely, that in which the infection, having implicated the periosteum, had passed by vascular channels into the bone tissues of the sinus capsule. He then related the clinical manifestations to these five types. The signs and symptoms of the oedematous type were those described in dealing with chronic catarrh of the antrum, adding only that any distal clinical manifestations to which it might give rise were due to surface rather than to vascular transmission of infection. The

infiltrative type included a large majority of the cases of chronic pyogenic sinusitis so familiar to nasal surgeons. If infection were limited to the more superficial tissues of the muco-periosteum there would often be present, in addition to the ordinary local signs and symptoms of chronic antral suppuration, those which resulted from surface transmission of infection to adjacent or more distant regions. If and when superficial transmission of antral infection passed beyond the confines of the nasal cavities and their air cells, it might reach the conjunctivæ by means of the lachrymal ducts, the nasopharynx, the middle-ear clefts via the Eustachian tubes, and, passing downwards, involve the mucous membranes of the pharynx or larynx, lower air passages, and stomach.

The essential feature of the fibrotic and cystic types was fibrosis of the mucous membrane, with diminution of its cellular and glandular elements, the changes being most obvious in the deeper layers of the muco-periosteum. The local symptoms of this type of chronic pyogenic sinusitis were so familiar to nasal surgeons as to call for no comment, and the same assumption might be made concerning systemic symptoms of a toxæmic nature and such distant and localized manifestations as neuritis, myositis, certain types of arthritis, and cardiac disabilities.

OPERATION FOR INFECTIVE SINUSITIS

It must be within the experience of all nasal surgeons that many cases had been cured by a simple intranasal antrotomy, but for many years it had seemed to him that such results were due to luck rather than good management. The operator was working in the dark, and could not see the nature or extent of the disease which it was his duty to remove. These essentials could only be obtained by a full exposure, such as was afforded by the Caldwell-Luc procedure in antral sinusitis, or an external operation, such as Howarth's, for combined frontal sinus and ethmoid suppuration. That complete extirpation of an infected mucous membrane from an accessory nasal sinus might be followed by necrosis of bone or some other complication was a groundless fear, for it was known that within two or three months a new normal ciliated muco-periosteum would replace that which was removed. It was a little more than thirty years ago (1903) that he himself had emphasized this method of repair, in a paper before the old Odontological Society, and during the past ten years it had been amply verified by histopathological research carried out by a number of workers.

POST-OPERATIVE RECURRENCES

Finally, the lecturer turned to what he described as the most important phase of his task—namely, to endeavour to answer the question why well-executed operations for chronic pyogenic sinusitis were not infrequently followed by a recurrence of symptoms. During the last few years he had become more and more convinced that the continuation or recurrence of symptoms after the operative treatment of this condition was due to a residual infection in the bone tissues of a sinus capsule, and that it was one of the most potent foci for the vascular transmission of septic organisms and their toxins. This view had received less practical recognition from rhinologists than from dental surgeons, and the present occasion seemed opportune for laying further emphasis on this factor. If and when pyogenic organisms could be demonstrated in the inflamed osseous tissues, such a residual infection would surely explain why free drainage and complete removal of the muco-periosteum might not suffice to prevent a recurrence of symptoms. Material additional to his own was collected from all the nasal sinuses and investigated by Dr. Albert Gray in the Ferens Institute of the Middlesex Hospital. Mr. Tilley showed some convincing photomicrographs of the histopathological sections so skilfully obtained.

He was not aware of any clinical manifestations of chronic "silent" osteitis of an air capsule which were pathognomonic of that condition, but it might be suspected when spontaneous local pain was a prominent symptom or if the bone was tender to pressure. It

was in such cases that general or localized evidence of blood-borne infection might overshadow local manifestations of suppuration.

With regard to treatment, if on removing a pyogenic membrane from a nasal accessory sinus, pus or even pinpoint collections of it were seen beneath the periosteum, the adjoining bone should be uncapped, and if found infected removed until healthy osseous tissue was reached. If no evidence of subperiosteal osteitis were detected during the primary operation, and there was recurrence of symptoms, bone infection should be inferred and prompt measures taken to remove it. Nasal washes, local applications, and all such meddlesome interference would be of so little avail that the long-suffering patient might well exclaim with the Psalmist, "My bones are vexed, my soul also is sore vexed," and the cynic might be prompted to utter again that opprobrious dictum, "Once a sinus operation, always a sinus operation."

CHARING CROSS HOSPITAL MEDICAL SCHOOL

INAUGURATION OF CENTENARY APPEAL

The first public appeal since its foundation one hundred years ago was launched by the Charing Cross Hospital Medical School at the annual presentation of prizes, held at the hospital on November 1st. The inaugural address was to have been given by Air Marshal Sir John M. Salmond, but owing to illness his place was taken by Air Vice-Marshal C. A. H. Longcroft. The proceedings were presided over by Major Colin Cooper. The report of the dean (Mr. Eric A. Crook) was congratulatory to many members of the staff and students on receiving distinctions. It also mentioned, among other items of interest, that this year the Huxley Memorial Lecture had been delivered by Professor Julian Huxley, grandson of T. H. Huxley, who was one of the most famous of the school's past students, David Livingstone being another.

INAUGURAL ADDRESS

Air Vice-Marshal Longcroft, after presenting the awards to the successful students, read the speech which Sir John Salmond had intended to deliver. He said that for a hundred years Charing Cross Hospital Medical School, by its teaching and assiduous research work, had advanced the cause of science without any public appeal. The founder was Dr. Benjamin Golding, who, in 1823, conducted a general infirmary and dispensary in Villiers Street, close to the present hospital. The foundation stone of the present Charing Cross Hospital was laid eight years later, and the hospital was formally opened at the beginning of 1834 by the reception of in-patients; the medical school was inaugurated in the same year. He added that it was a tribute to the foresight of the founder that when the Royal Charter was granted fifty years later no alteration was found necessary in any detail of the original constitution. The financial and administrative regulations made so long ago for combining the hospital and medical school had stood the test of time and were still operative. From twenty-two students a hundred years ago the number had grown until there were now 150 full-time students on the books, and the school had its own building, laboratories, lecture theatre, and museum. No organization of value to the common weal, Sir John Salmond added, could stand still; it must either expand to meet the ever-increasing requirements of the modern world or it must contract and fade away. On the technical side, with the existing facilities, only the requisite minimum of instruction could be given in pathology. Nor could a building established sixty years ago meet the essential requirements of to-day. Therefore an appeal was being made for £7,500 to extend the school building; £2,500 to liquidate the debt; £10,000 to complete the establishment of a chair in pathology; £20,000 for the provision of a hostel for students; and £10,000 towards the endowment of scholarships. He reminded the company that Huxley, of immortal fame, might have

languished as an apothecary's assistant had it not been for the opportunity of gratuitous tuition. Unlike other appeals for hospital facilities, said Sir John Salmond in conclusion, this first public appeal for the modest total of £50,000 was to strengthen and increase the flow of healing waters at their source.

VOTE OF THANKS

A vote of thanks to Air Vice-Marshal Longcroft was proposed by Dr. Gordon M. Holmes and seconded by Mr. Philip Inman, managing governor of the hospital; a further vote of thanks to the chairman was proposed by Mr. J. Bright Banister and seconded by Mr. Norman Lake.

Major Colin Cooper, in reply, said that the appeal would be launched to bankers, business houses, and public institutions, to all friends of Charing Cross Hospital, and to the great charitable British public. It was most important that the progress made by Charing Cross Hospital during the last hundred years should not be arrested in this generation. As an appeal should have a good send-off, he desired, in memory of those who fell in the Flying Corps during the war, to start it with £1,000.

The guests were afterwards entertained to tea in the refectory of the medical school, and a demonstration was given in the Institute of Pathology. An excellently produced appeal brochure was distributed, containing illustrated historical notes on the hospital and school, and specifying, in more detail, the objects of the appeal. With regard to the provision of hostel accommodation, which is one of the objects of the appeal, it is stated that there exists near the school a site on which a building could be erected to accommodate thirty-five or forty students. In connexion with the establishment of a chair in pathology, which is another of the objects, a fund already bequeathed for this purpose is expected to produce £600 a year, which will have to be supplemented in order that the occupant of the chair may receive a minimum salary of £1,000. The £10,000 asked for towards the endowment of scholarships will be used to provide for the award of entrance scholarships of £50 each, or £10 a year for five years; open scholarships of £75 each, or £25 a year for three years (covering the clinical period only); and clinical scholarships of £120 each, or £40 a year (equal to the whole of the tuition fees) for three years.

PREPARATORY SCHOOL SCHOLARSHIPS FOR SONS OF MEDICAL MEN

We take this opportunity of drawing the attention of medical men to the annual award of two scholarships of £100 each at Port Regis Preparatory School, Broadstairs, Kent. These scholarships were recently founded by Sir Milsom Rees, and the next examination will be held on March 5th, 1935. Candidates must be under 9 years of age at the time of competing, and the scholarships are normally tenable till the holder leaves the school. They will be selected at an interview in London from among those boys who have done best in some simple examination conducted in or near their homes.

Applications for these scholarships must be addressed to the Head Master, Port Regis School, Broadstairs, to reach him not later than February 20th, 1935. Full particulars may be obtained from him.

At a meeting of the Continental Anglo-American Medical Society held in Paris on October 6th, with the vice-president, Dr. Leonard Robinson, in the chair, it was agreed that a scientific programme should be given on the Riviera at a time and place to be decided by members practising there, preferably during the Christmas vacation, and that a clinic should be given at the American Hospital by the Paris members during the meeting next May. The exact date of these gatherings will be announced later. British and American graduates travelling, or residing in the neighbourhood, are invited to attend.

THE BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

ANNUAL DINNER

The fourth dinner of the British College of Obstetricians and Gynaecologists was held at Claridge's Hotel on November 5th, Dr. JOHN S. FAIRBAIRN presiding.

MR. BALDWIN'S SPEECH

The toast of "The College" was proposed by Mr. Stanley Baldwin. He said that the College hoped to do for obstetrics and gynaecology what the College of Physicians did for medicine and the College of Surgeons for surgery. Until recently obstetrics and gynaecology had had no body to speak on its behalf. There was no doubt that, with all the social work that had been done in connexion with sanitation, housing, and old-age pensions, the question of maternal mortality and child welfare had come before the country in a way it had not done previously, and not before it was necessary. During the present century the general death rate had been reduced by a third, as had the tuberculosis mortality, and infant mortality had been reduced by nearly one-half, but the maternal death rate was slightly increasing. The Departmental Committee on Maternal Mortality had found that one-half of the maternal deaths in this country were preventable. That was a terrible indictment. For all the deaths that occurred there were, as a result of neglect, also the disabilities in later life among women who had borne children. He had been told that if all the women in Britain received proper attention before, during, and after childbirth the occupation of beds in the women's wards in hospitals would be reduced by one-half. There were black spots in this country where maternal mortality had reached appalling proportions.

The College might be of invaluable service to the country in connexion with hospitals for women and welfare centres for children. The standard of the College was high and must always be high, and he would urge it to seek closer co-operation with the Medical Research Council, and to direct research into the question of maternal mortality. It seemed to him as a layman that there might be some factor to account for the high figures of mortality in childbirth which had hitherto eluded their vigilance, and that there must be something to be discovered. He would say to them: "Get to it." Also, he wanted to see the day come when the best form of anaesthesia for use in childbirth should be within the reach of every woman in the kingdom. In conclusion, Mr. Baldwin said there was an immense amount of work to be done to reduce maternal mortality, and that if the Government could help in any way it would be glad to do so; somehow or other it meant to clear this blot off the national slate.

THE RESPONSE

In response to the toast the President, Dr. FAIRBAIRN, on behalf of the College, thanked Mr. Baldwin for coming to dine with them. A young society like theirs, with only a future before it, needed some support from the State. During the five years of its existence the College of Obstetricians and Gynaecologists had made good progress, and now had a house and a library of its own. This in large measure had been made possible by their benefactor, Lord Riddell. The desire to be of public service had been in the minds of the founders of the College and its first council, but of necessity they had been much preoccupied with questions of organization. Due tribute must be paid to the former Obstetrical Society of London, now the Section of Obstetrics of the Royal Society of Medicine, for its good work in connexion with the

maternity services and the education of midwives in this country. Dr. Fairbairn then outlined, in some detail, the various activities of the College, and referred to the institution of the diploma, which was to encourage general practitioners to act as consultants in midwifery in those areas in which specialists were not available, particularly in the black areas in the North of England.

The toast of "The Guests" was proposed by Professor C. G. LOWRY in a speech happily blended with wit and good sense. Sir GEORGE BUCHANAN, Master of the Society of Apothecaries, replied.

Doba et Vetera

ANCIENT HINDU-ARYAN MEDICINE

The following is an abridged version of the presidential address by Dr. E. W. Lewis which he gave to the Lancashire and Cheshire Branch of the British Medical Association at its recent annual general meeting.

Following my house-surgeoncy days, I spent seven years in hospital work in South India. Now and again I came across customs and treatments that made me interested in the history of Indian medicine. I soon discovered that from 1000 B.C. until A.D. 100 the condition of medical culture and teaching, and the success and extent of medical treatment, were higher than in any other country. Why did India not continue to develop her medical learning? Why did the medical knowledge of the Indo-Aryans retrogress?

Three epochs are definable: the Vedic, extending from the first migration of the Hindus into the Punjab to about 800 B.C.; the Brahminic, representing the Indian Middle Ages, the Golden Age of Indian medicine; and the third, which began about A.D. 100, with the Arabic invasions. The Rig-Veda (about 1500 B.C.) contains definite medical instruction, and reveals the origin of medicine in theurgy and empiricism. There is an attempt to distinguish such conditions as vertigo, dropsy, epilepsy, heart disease, jaundice, and hemiplegia. On the surgical side the extraction of arrows, the dressing of wounds, the making of artificial limbs, and castration are dealt with. Medical treatment was carried out by means of charms and medicinal herbs. Among the earliest remedies described were those for promoting conception, aphrodisiacs, and abortifacients. Isopathic and homoeopathic principles were in use, such as the employment of yellow plants in jaundice; hydrotherapy held high place. The Brahminic epoch was remarkable for the highly esteemed class of physicians, independent of the priesthood. These men were scientifically instructed, belonged to the high mixed caste of Ambastha or Vaidya, and were descended from Brahmins on the father's side. There was also an inferior class of assistants, the Vaisyas. Anatomy, materia medica, hygiene, dietetics, and surgery reached a high standard. With the coming of the Arabic invaders the theories and practice of Ayur Vedic medicine were submerged by the Yunani system. Progress in investigation ceased, the standard of practice and training declined, and incapable men and quacks multiplied.

The second epoch deserves fuller consideration. The two chief sources of information are the books written by Charaka and Sushruta. The choice of the profession of medicine was conditional on good descent, preferably from a medical family; manual dexterity; and the possession of certain physical as well as moral and intellectual endowments. Training lasted six years, was based upon a recognized and approved textbook, and comprised the learning of precepts, clinical instruction, visiting the sick, and undertaking surgical procedures. It was laid down that medicine and surgery had to be mastered equally, since "the physician who lacks knowledge of one of these branches is like a bird with only one wing." The physician was enjoined to widen his knowledge through intercourse with his professional brethren, so that the light of wisdom should not be hidden from him. The instructions regarding fees are interesting. "Price will

vary with the rank and condition of the patient. Money will be the recompense bestowed by the rich; friendship, reputation, increase of virtue, prayers, and gratitude will be that of the poor. When a Brahmin or a religious mendicant, a relative, a humble and good friend, or one without relations consults a physician, he must not accept of any pecuniary recompense; his reward in such cases will be an increase of knowledge and the gratification of his desires in having had an opportunity of performing a good action." Warning is given repeatedly about treating incurable cases. For instance, in treating serious abdominal conditions, the cause of which was doubtful, an Indian physician was instructed before commencing treatment to inform the friends that the disease was incurable; then he might try the effects of remedies.

All Indian medicine was founded on the writings of Charaka and Sushruta; later writings follow them, and are content to be commentaries on the original work and to complete and improve these through fresh experience without interfering with the theoretical groundwork or the old-time formulas. No work could receive acknowledgement or be accepted unless it could claim to have been the result of Divine revelation.

STANDARDS ATTAINED

Anatomy.—Hindu philosophers, although opposed by strong prejudice, entertained sound and philosophical views respecting the uses of the dead to the living, and were the first scientific cultivators of practical anatomy. No attempt was made to preserve the bodies by embalming or arterial injections, but rules were laid down as regards cleansing and the promoting of decomposition. The surface of the body was then removed by a brush made of reeds, hair, or bamboo bark, the skin, flesh, and adjacent structures being carefully observed before removal. With this method of dissection it will be readily seen that Indian anatomy did not consist of real intimate knowledge, but merely of an enumeration and classification of the constituent parts of the body. Nevertheless, some idea of the organs was obtained, and bones, ligaments, and joints were described, though the actual course of such structures as veins, arteries, and nerves were not known. Indeed, nerves, vessels, and cavities were all confounded. Something was known of the spinal cord. The central canal, with its continuation with the lateral ventricles of the brain, the cerebral convolutions, and the distinction between white and grey matter, for instance, were indicated in the *Shiva Samhita*.

Physiology.—Such imperfect knowledge of anatomy gave rise to highly speculative physiology, in which observations were accounted for by theories. Hindu sages observed the great influence of the fluids in disease, and, imperfectly acquainted with the structures and uses of the various parts of the system, endeavoured to explain the functions of the organs by the action of fluids upon them, reducing their physiological opinions to an ingenious system—the humoral physiology—on which the whole of ancient Hindu medicine was founded. The fundamental parts of the body were *Vayu* (wind), *Pitta* (bile), and *Kafa* (phlegm). "As the moon sheds moisture and abstracts the sun's rays, which dry up and bestow energy upon the earth, and as the air moves from place to place, so does phlegm bestow moisture, bile withdraws it by its heat, and wind wafts it about the microcosm or animal body." This theory, derived from the Hindus, was for many ages universally believed, and adopted by the Egyptian and Greek priest-hoods. The essential parts of the body were noted as: chyle; blood; *Mansa*, or flesh, produced by the *Vayu* thickening the blood; fat, generated by the digestion of the blood by the internal fires; bone and cartilage; marrow, including the brain; and semen. The "excretories" composed a third section; ranked as impurities, they included "oily exudations, seminal fluids, blood, dandruff, urine, faeces, ear-wax, nail parings, phlegm from the throat, etc., tears, concretions in the eye, and sweat."

Diagnosis.—For ascertaining the nature of disease physicians examined first the appearance, the countenance, and tongue; then, by touch, feeling the pulse and temperature; and thirdly by questions into the medical and

general history. The senses of taste and smell also were used. The weakness or loudness of speech was noted. The pulse was felt with three fingers; in the male the right radial pulse was felt, in the female the left. Attention was paid to compressibility, frequency, regularity, size, and the different impressions it produced on the fingers.

Hygiene and Public Health.—Health precepts have been in force for 3,000 years, backed by religion. These laws prescribe strictly the mode of life; the hour and method of rising; attention to the calls of nature; cleaning of the teeth, tongue, and nose; bathing; shampooing; massage; inunctions; resting; exercise; diet; clothing; housing; sleeping; and climatic changes.

Midwifery.—Rules for the conduct of labour were strictly laid down, covering the size and ventilation of the room, the cleanliness of the hands of the attendants, lubrication of the vagina and perineum with sweet oil, and encouragement of the patient. The humoral theory comes into the physiology of parturition. "By the wind of the pelvis the foetus is expelled, as an arrow is shot from a bow, and falls insensible to the ground. All its former knowledge is immediately forgotten, and, losing so many pleasing illusions, it cries." Five classes of barren women were enumerated: (1) the crow-barren, who only bear once in a lifetime; (2) those incapable of conceiving; (3) those who conceive but always miscarry; (4) those whose offspring do not survive their birth; and (5) those sterile on account of physical weakness. All except the first class were considered capable of being cured by appropriate medical treatment. If labour was delayed, sneezing and straining were induced by the application of the smoke of the burnt skin of a black serpent, or the tickling of the throat with a finger covered with hair. These measures were also used for the retained secundines. Internal turning was practised. If this was not successful, dismemberment of the foetus was performed, the various parts being extracted with a hook. The indications for Caesarean section were laid down; this operation was first performed by Sushruta.

Medicine.—Classification of diseases was very confused, due to the adherence to the humoral theory. Many were recognized, however, and suitably dealt with: for instance, chest diseases such as asthma (treated with *datura*), bronchitis, pneumonia, phthisis (treated with garlic), heart disease and angina (treated with cardamoms), diabetes mellitus, jaundice, anaemia (treated with iron preparations), cholera, dysentery (treated with bael fruit), nervous diseases such as apoplexy, epilepsy, hemiplegia, various paralyses, and tetanus, and skin diseases such as eczema and venereal affections. The system of giving poisonous drugs in increasing doses to a maximum, and then decreasing regularly to finish the course, was well known. The use of the cautery, the production of emesis at regular intervals, and blood-letting by leeches, cupping, and venesection were very carefully described and performed.

Surgery.—This was held to be the chief of the medical sciences, and practical instruction was very carefully given. After the student had been taught from books, different operations were demonstrated to him upon wax spread on a board, gourds, cucumbers, and other soft fruits; tapping and puncturing on a leather bag full of water or soft mud; scarifications and blood-letting on fresh hides of animals from which the hair had been removed, and upon the vessels of dead bodies; puncturing and lancing on the hollow stalks of water-lilies; and teeth extraction on dead animals. The ancient Hindus used steel surgical instruments, and had a great variety. Foreign bodies were removed from the throat by probangs, as well as in other ways. Amputations were carried out boldly, boiling oil, pitch, and pressure bandages being used to check haemorrhage. Perineal lithotomy was frequently performed as vesical calculus was very common. Abdominal obstruction was dealt with by laparotomy. Hernias were treated by irritant plasters or the actual cautery over the neck of the canal so as to produce adhesive inflammation. Fractures and dislocations were carefully set, and trephining successfully accomplished. New noses and ears were fashioned with wonderful skill,

and lens couching in cataract was common. Anaesthetic drugs such as soma juice and sammohini were administered.

THE PERIOD OF DECADENCE

Such being the attainments and knowledge of the ancient Hindu-Aryan surgeons and physicians, what were the causes of decline? Three factors seem to have been operative. First, the heat and conditions of the country in some small measure contributed to the reduction of that energy so necessary for the continued investigation and practice of medical work. Next, with the Mohammedan conquests, bigoted prejudices in favour of the Yunani system brought about the ignoring of science and the replacement of observation and reasoning by theorizing. The third, and probably the greatest, factor in the decline was religious. No criticism was allowed of any of the facts and deductions in the reputedly inspired volumes. Thus no advance was made, no correction of mistakes was possible, and stagnation ensued. A religious interdict was issued against every occupation involving contact with a corpse; the study of anatomy and pathology stopped. Investigation for the sake of man's health was banned if it involved animals or men. Asoka in 220 B.C. had established a public health service and hospital accommodation, his edicts being carved on rocks, but the complete arrest of experimental work brought to an end the wonderful ancient standards of Hindu-Aryan medicine.

France

[FROM OUR CORRESPONDENT IN PARIS]

Future of the Pasteur Institute

Pasteur was much more than a Frenchman, and the Institute to which he gave his name has always faithfully reflected his cosmopolitan outlook. Many of the greatest names associated with this Institute are those of foreigners, and long may the whole world of medicine continue to feel at home in it. The Institute began very modestly in 1886 as a centre for the treatment of rabies. The meagre funds and modest quarters attracted big men: Duclaux in charge of general bacteriology, and Roux teaching technical bacteriology; Chamberland in charge of anthrax vaccination, and Grancher of antirabic vaccination. Presently Metchnikoff threw in his lot with this small group, and each in his turn attracted new disciples. In Roux' service were Nicolle, Yersin, Borrel, and Calmette. Collaborating with Metchnikoff were Bordet and Salimbeni, and so on. There were giants in those days. After Pasteur's death in 1895 the momentum given by his personality continued. Funds and housing accommodation grew. A large building devoted to biological chemistry sprang up over the way, on the other side of the Rue Dutot; close to it there arose a hospital for the treatment and study of infectious diseases; and only three years ago a new block of buildings was inaugurated, an outward and visible sign of Calmette's B.C.G. activities. In less than half a century the Pasteur Institute had grown from nothing into a vast centre of research. Its organization and direction were unchallenged; Pasteur's mantle had fallen on Roux, and when he should be gathered to his fathers the succession seemed secure with such a man as Calmette, already helping Roux to hold the reins. And then Calmette died five days before Roux. The situation was critical. The Executive Committee of twelve members, one of whom was the late Raymond Poincaré, appointed a Commission, composed of certain members of the Executive Committee, to study the administration and scientific organization of the Institute and the means to assure the continuity of Pasteur's enterprise. After deliberating for six months the Commission reported. Its conclusions were adopted by the Executive Committee, and the Institute is henceforth to be under a director and an assistant director, and to

enjoy the services of a Scientific Council with exclusively advisory functions. This Scientific Council is under the authority of the Executive Committee, and its members are: Bertrand, Bordet, Borrel, Mesnil, Charles Nicolle, and Yersin, all disciples of Pasteur. Louis Martin is director, and Ramon, of anatoxin fame, is assistant director.

Dr. Paul Durand

French doctors have discovered a Sir James Mackenzie in their midst. During the past few years collective research by general practitioners has been conducted under the auspices of the *Assemblée Française de Médecine Générale*, an association which encourages the pooling of clinical observations by the general practitioner and their discussion from time to time in Paris under the chairmanship of some acknowledged leader among the consultants. Since 1932, and at every one of a dozen successive meetings, a general practitioner has presented a series of clinical and epidemiological studies conducted during a lifetime in the country. His name is Paul Durand, and his colleagues' esteem has found expression in the invitation extended to him to preside at the meeting on November 4th, when the subject under discussion was "Diphtheria: Its Serum and Vaccine Treatment."

A Surgical Congress

Three principal subjects were discussed at the forty-third French Surgical Congress, which was held between October 8th and 13th: the fourth venereal disease, suppurative arthritis of the knee, and the surgery of the suprarenals. The discussion on the treatment of the suppurating knee-joint must have given most listeners the impression that surgery is a house divided against itself, and that we have still a long way to go before we find a treatment which most surgeons will accept as rational. Much more unanimity, of a pleasingly complacent character, was shown in the discussion on lymphogranulomatosis, Nicolas-Favre's disease, or the fourth venereal disease. Among those who took part in this discussion was Professor Frei of Berlin, whose name is associated with the reaction on which the diagnosis of lymphogranulomatosis depends.

"Covering"

To what extent may a French doctor employ a nurse without laying himself open to the accusation of "covering"? This question has been raised so often of late that a member of the editorial staff of *Concours Médical*, Dr. Paul Boudin, has taken the trouble to delve and dive into legal records. He has emerged from this ordeal with alarmingly instructive observations. According to a judgement of the Tribunal Civil de la Seine in 1906, a hydropic injection is minor surgery. It must therefore be undertaken by the doctor himself, or in his presence, or under his supervision and direct control. This operation, according to the aforesaid judgement, does not come within the scope of the nurse in the execution of a doctor's orders. Be it noted that the nurse of 1906, with the exception of the Sister of Mercy, was not always the embodiment of, or the last word in, surgical cleanliness, and the interpreters of the law may be excused, and even cautiously commended, for the limitations they imposed on her activities. But the standards of nursing have vastly improved during the past score of years, and the French nurse of to-day practises this minor surgery with equal skill and impunity. When an Anglo-Saxon practitioner recommends a tablespoonful three times a day after meals, his confrere over here prescribes "piqûres"; and even if the law courts were to persist in defining them as minor surgery, the nurse is not likely to hold her hand as long as she is encouraged by the doctor under whom she works to prick his patients.

England and Wales

Conference on Health Education

The seventh Annual Conference on Health Education organized by the Central Council for Health Education, will be held on Thursday, November 22nd, in the lecture theatre of the London School of Hygiene and Tropical Medicine. Sir George Newman, as president of the conference, will deliver an inaugural address at 11 a.m. A discussion on "The Education of the Public with Regard to Nutrition" will be opened by Professor J. A. Nixon of Bristol University, and Dr. W. G. Savage, county medical officer of health, Somerset. Dr. James Fenton, chairman of the Central Council, will speak at the beginning of the afternoon session at 2.30 p.m., after which the discussion on nutrition will be concluded. A second discussion, on "The Education of the Public with Regard to the Consumption of Milk," will be opened at about 4.15 p.m. by Dr. Thomas Orr, medical officer of health, Ealing, and chairman of the Publicity Committee, National Milk Publicity Council. At the close two new films, one on "Infant Management," will be shown. The Minister of Health has sanctioned the payment of expenses of two delegates from each local authority, and it is hoped that a large number of delegates will be appointed. The names and addresses of such delegates should be forwarded not later than November 16th to the Central Council for Health Education, 1, Upper Montague Street, Russell Square, W.C.1, whence further information about the conference may be obtained.

St. George's Hospital

At a special court of the governors of St. George's Hospital, London, held on October 31st, with the treasurer, Lord Greville, in the chair, the following resolution was adopted: "That the House Committee be authorized to draw up a scheme for the rebuilding of the hospital either on the present site or elsewhere with an appeal for funds for this purpose." A special committee will be appointed immediately to give effect to the terms of the resolution. H.R.H. the Duke of Kent, president of the hospital, recently agreed to a suggestion that intended wedding presents from the public should take the form of donations to the fund for the rebuilding of St. George's.

Midland Mental Pathological Society

A society has been formed, with headquarters in Birmingham, to promote co-operation among those interested in the study of the pathological basis of mental disorder and defect. Its origin dates back to November 27th, 1933, when thirty-four medically qualified superintendents and assistants from the various mental hospitals of the Midlands met at Hollymoor Mental Hospital, and an address was given by Dr. F. A. Pickworth, director of the City and University of Birmingham Joint Board of Research for Mental Disease. On that occasion Dr. H. Frieze Stephens emphasized the need of a society to hold meetings at which pathological problems, such as had arisen out of the demonstration of research work that day, could be discussed also with pathologists from general hospitals. The Midland Mental Pathological Society held its inaugural meeting on October 31st, 1934, those present numbering forty-two, and several others had signified their intention of joining. An address by the president, Sir Gilbert Barling, Bt., F.R.C.S., chairman of the Joint Board, was warmly received, and a formal resolution to found the society was proposed and discussed by Drs. B. H. Shaw, H. F.

Fenton, A. M. McCutcheon, Frieze Stephens, and W. A. Potts. Dr. Pickworth was appointed honorary secretary and treasurer, and Dr. Shaw chairman of the committee for 1934-5. After the approval of rules and regulations, and votes of thanks to the University of Birmingham and to the dean of the Medical Faculty, Dr. R. D. Lockhart gave a lantern demonstration of "Naked-eye Blunt Dissection of the Brain," showing with remarkable clearness the various important nerve tracts of the mid-brain and brain stem, including his own discovery of the commissure connecting the optic lobes of the cerebrum. He showed also sections of the whole brain made with Hamilton's microtome, and demonstrated the instrument. The society fulfils a much-needed association between those engaged in the study of mental disease and general medicine, and promises enthusiastic and lively discussions at future meetings. Membership (apart from honorary members) is restricted to those connected with medical or mental institutions in the Midlands, to whom Dr. Pickworth (Hollymoor, Northfield, Birmingham) will be pleased to send information:

The City of London

Public health conditions in the 661 acres which constitute the City of London (excluding the Temple) are in some measure exceptional. The resident population is still declining, while the number of those who visit it and leave it daily is rising. The estimated population for 1933 is given in the annual report, for that year, of Dr. W. M. Willoughby, medical officer of health, as 9,830; the death rate is only 10.9 per 1,000, as compared with 12.2 for 118 great towns of England and Wales, and 12.2 for the metropolis as a whole. The City therefore can be regarded as one of the healthiest residential parts of London, and shows relatively low figures for the incidence and mortality rates of zymotic diseases and phthisis. Considerable use is made of the facilities provided by St. Bartholomew's Hospital. The City Maternity and Child Welfare Centre is accommodated there, and was reorganized at the beginning of last year, innovations then introduced including the appointment of a medical officer to attend the sessions, and of a trained health worker to visit the infants in their homes and to carry out the non-medical duties at the weekly sessions. Of the 219 infants under the age of 2 years in the City, 164 attended the centre during 1933, the total attendances numbering 1,800. This represents a high percentage of the infant population, and is attributed to the home visiting. One of the most satisfactory features of the centre is its close association with the children's department of the hospital. Although the centre is conducted as an entirely separate enterprise for the management of healthy infants, it is possible for the mothers to get advice at the hospital if their children should become ill between the sessions, and the transference of a sick child to the children's department is a very simple matter. As regards maternal mortality, only sixteen maternal deaths occurred among City residents from 1900 to 1933 inclusive. Co-operation between the Blind Persons Act Committee and the Infant Welfare Act Committee has now been established in the City. Since the close liaison with St. Bartholomew's Hospital also covers the treatment of venereal diseases, effective work can be done, and the services of an ophthalmologist have been obtained through the hospital. The Metropolitan Society for the Blind, which is the agent for the City Corporation, reports that the City blind number only fifteen, all of whom are over the age of 30. During past years certain difficulties have arisen with regard to persons diagnosed as tuberculous and resident at the places where they were employed. There is normally a period of two to three weeks before these patients can be admitted to an institution controlled by the London County Council,

and in such cases more prompt removal is essential. Arrangements have been made, therefore, with the Brompton Hospital for Consumption, whereby these patients can be removed to that institution as in-patients within forty-eight hours, under a certificate supplied by the medical officer of health. No special points have been noted as regards the incidence of tuberculosis, and the records do not show that the pulmonary form is specially prevalent among any class of workers in the City.

Housing in Cardiff

Cardiff has relatively few houses which are old, worn out, or for other reasons unfitted for human habitation. But it has its own "slum problem," inasmuch as overcrowding continues from year to year in consequence of the evil practice of multiple tenancy, and this in spite of the fact that 9,215 houses have been built since the war by the City Council and by private enterprise. As elsewhere, difficulty has been experienced in providing houses in sufficient numbers and suitably placed from the point of view of access to the main centres of employment. Prospective tenants are unwilling to move far away from the centre of the city for fear of incurring added expense in travelling to and from their work. This overcrowding is reflected in the annual report of the medical officer of health, where it is shown that only 122 out of 279 new cases of pulmonary tuberculosis had sleeping rooms to themselves, and that the number of contacts exposed to infection in the same bedrooms as tuberculous patients was 243. A further survey of the city was carried out during 1933 for the purpose of ascertaining the number of houses that were unfit for human habitation and incapable of being rendered fit at a reasonable cost. A total of 207 houses in such a condition were scheduled for demolition. The policy of the city council has been to group as many as possible of these houses into areas, so that they could be dealt with in accordance with the provisions of Part I of the Housing Act of 1930. Representations have been made regarding seventeen clearance areas, including a total of 151 houses and seven other buildings. The houses in these areas contain 165 families with a total of 634 persons. Outside the scheduled areas there are fifty-six houses which are unfit for human habitation, containing fifty-nine families consisting of 192 persons. It will be seen, therefore, that the total numbers of families and persons to be displaced are 224 and 826 respectively. The control exercised by the public health department on the corporation housing estates has led to a progressive reduction in the proportion of vacant houses found to be verminous, the percentage having fallen from 30.5 in 1930 to 20.5 in 1933. Dr. Greenwood Wilson became medical officer of health on December 1st, 1933, in place of Professor R. M. F. Picken, who resigned at the end of September to occupy the Mansel Talbot chair of preventive medicine, having then completed twelve years of service as Cardiff's third medical officer of health since 1854.

Tuberculosis in Lancashire

An index has been provided in the comprehensive report for the year 1933 of the central tuberculosis officer of the Lancashire County Council; it reveals the extent of the work most vividly. For instance, under "Treatment" are listed references to artificial light, artificial pneumothorax, crissoline, home, hydriocarpates, inhalation therapy, institutional (pulmonary and non-pulmonary), phrenicectomy, sanocrysin, and thoracoplasty, while there are seven different references under the heading "Deaths from Tuberculosis." Another feature is the arrangement of much of the report in the form of short articles on the various subjects. Dr. Lissant Cox reprints his article on the place and uses of the tuberculosis dispensary, which

was the opening paper in the discussion on this subject at the annual conference of the National Society for the Prevention of Tuberculosis in London last June. This is followed by a chapter on the question whether recovered tuberculous cases relapse, in which it is shown that 96.6 per cent. of the patients written off as cured did not return to the dispensary, while the percentage not returning of those who at some time had had a positive sputum was 96.8. Dr. Lissant Cox then deals with the question whether children rejected as non-tuberculous develop tuberculosis in adolescence, and concludes that the conservative standard of diagnosis of pulmonary tuberculosis in children adopted in Lancashire appears to be justified by the results, while the consequent saving in sanatorium beds is a public benefit. Of 3,556 young adults who came on the dispensary registers as definite cases of tuberculosis in the period 1927-33, and who could therefore have been seen as children in or after 1913, only thirty had been rejected in childhood as not suffering from the pulmonary form of the disease. Even in these thirty some allowance must be made for the contraction of infection from existing cases in adolescence. Moreover, an examination of the 686 deaths from tuberculosis in the seven years 1927-33 of persons not notified as tuberculous during life does not reveal the name of a single person who had been rejected at the dispensaries as non-tuberculous in childhood. A chapter on actinotherapy at the Eccles dispensary contains the information that 82 per cent. of the 152 patients who were discharged from the light clinic during the period 1927-30 as quiescent and apparently well, and no less than 96 per cent. of the adenitis cases, were still quiescent after three to six years. A survey of sixty-four cases of artificial pneumothorax matched with controls in a pulmonary hospital indicates the superiority of this form of treatment, especially when the extent of lung involvement is small. The youth or otherwise of the patients is less important, and even when the treatment was unsuccessful the survival rate was unimpaired. The tabulated after-histories of the adult pulmonary patients who came on the dispensary registers during the years 1920, 1925, and 1930 indicate but little improvement in 1925 over 1920—five years in which very little collapse therapy was attempted—while there is a slight but definite gain in 1930. Another table of the after-histories of patients suffering from non-pulmonary tuberculosis reveals slightly better results in 1930 as compared with the previous year. Between 70 and 74 per cent. of adults and 81 and 86 per cent. of the children recovered from their disease, or reached a stage where it was arrested or quiescent. In addition to carefully argued statements of this kind there is the usual mass of details, both clinical and administrative, which render this report even more instructive than its predecessors.

Scotland

Treatment of Mental Disease

In an address to the Edinburgh Women Citizens' Association, on "Mental Hospitals and Institutions," Dr. Hamilton Marr, Commissioner to the General Board of Control for Scotland, said that the limited teaching on the subject of mental disease in the medical schools acted unfairly towards the general practitioner, on whom the community was dependent for the thoroughness of its medical care. At the present time a knowledge of mental problems was restricted to the medical men who came into actual contact with the insane in asylums or mental hospitals. The number of teachers of psychiatry in this country could be counted on the fingers, but the day was approaching when a special diploma would be necessary

for the practice of psychiatry, just as it now was for the practice of public health. It was now recognized that mental disorder should not be neglected until the affected person became certifiable, but treated in early stages and under hospital conditions. There should be certification only in the case of those patients who were dangerous to themselves or to others, and who refused to avail themselves of care and treatment and required to be detained under legal warrant. He suggested that Scotland should be divided into four districts, each grouped round a university centre and provided with a central psychiatric hospital and outdoor department. Such hospitals would be conducted on the same lines as the large general hospitals, and attached to each there should be throughout the district subsidiary clinics and outdoor departments. The central hospitals, managed by special district committees, would be available for every person who required advice and help. They would be equipped with all known aids to diagnosis, care, and treatment, and for research into the many unsolved problems of the cause and treatment of mental disorder. This scheme, if attained, would make for efficiency and economy, and there would be no necessity to add to the present mental hospitals or to erect new asylums. Dr. Marr believed that an appeal to the public for contributions to such psychiatric hospitals would, even in these times of financial stringency, receive an unexpected response, and the scheme could be inaugurated if local authorities were required to give the equivalent of the old lunacy grant, which was at present included in the Government block grants. It would undoubtedly lead to a reduction in the incidence of mental disorder throughout Scotland, and the accumulation of chronic mental cases would be notably diminished.

Ireland

Vital Statistics for Northern Ireland

The annual report of the Registrar-General for Northern Ireland for the year 1933 has now been published,¹ and in addition to the usual information concerning marriages, births, and deaths it contains a résumé of the administration of the Registration Acts. It appears that the state of registration in Northern Ireland leaves much to be desired; during the present century alone some thousands of births and deaths have escaped notification. The appropriate Acts have been in force for seventy years, and it seems very remarkable that there should still be such a measure of non-compliance with their provisions. There were 24,601 births registered during the year, representing a birth rate of 19.4 per 1,000 of the estimated population. This rate is the lowest recorded for Northern Ireland, but, notwithstanding the continued fall, it is the highest recorded in the British Isles for the year. The number of deaths registered was 18,154, giving a rate of 14.3 per 1,000. This shows a slight increase when compared with the rate for 1932, the increase being largely due to the epidemic of influenza which occurred in the early part of the year. The death rate of 1.15 per 1,000 from all forms of tuberculosis represents the first check since 1925 to the downward movement in the tuberculosis death rate, which had been falling since 1922. The increase, possibly arising out of the influenza epidemic, was peculiar to Northern Ireland, the rates in the other parts of the British Isles continuing to decline. The proportion of deaths from tuberculosis during the year at ages under 35 shows a reduction as compared with the figures of recent years, the proportion occurring at ages of 35 and over showing a corresponding increase. The death rate

from cancer, which was lower in 1932 than in 1931, was still lower in 1933. There was an improvement in the infant mortality rate, notwithstanding the warm, dry summer, when diarrhoeal diseases among children may be expected to be prevalent. The rate of 80 per 1,000 births registered, however, compares unfavourably with the infant mortality rates for England and Wales and the Irish Free State, which were 64 and 65 respectively. The maternal mortality rate for the year was 6.63 per 1,000 births, this being the highest figure recorded in the history of Northern Ireland.

Health of County Dublin

Dr. J. Harbison, in his monthly report to the County Dublin Board of Health, stated that the twenty-two cases of enteric fever in Swords Dispensary District occurred in Portrane Mental Hospital, where the outbreak was confined to one wing, in which a typhoid carrier was discovered. No case had been reported since October 2nd, and, presumably, the outbreak had subsided. Seven of the eight cases of diphtheria in Castletknock area occurred in an institution, where a diphtheria carrier was discovered; on removal of the carrier the outbreak subsided. The school medical inspection showed a marked increase in the number of children suffering from diseased tonsils and adenoids. Despite the full operation of the school meals scheme, the malnutrition figure was comparatively high.

Reports of Societies

PERSONAL FACTORS INFLUENCING ANAESTHESIA

In the Section of Anaesthetics of the Royal Society of Medicine on November 2nd Dr. H. P. CRAMPTON delivered his address from the chair, taking as his subject, "Factors, other than Anaesthetics, influencing Anaesthesia."

Dr. Crampton began by remarking that the modern anaesthetist had more drugs at his command than ever before, yet there remained certain factors influencing anaesthesia, apart from the drugs, the route, or the apparatus employed. He discussed them in three groups: the patient, the anaesthetist, and the surgeon and his operation. In the patient the mentality was more important than the physique. Large physique as such was not a drawback; some of his most satisfactory patients were guardsmen of large physique, but also of magnificent discipline, while the slender patient, if he or she had poor moral control, might be difficult. The way in which mentality affected anaesthesia was shown by "frightened" respiratory, cardiac, and spasmodic effects persisting after unconsciousness. Few people were in a state of real panic at the zero hour, but if real panic did persist it added a definite risk to any mode of induction. Most patients were mildly apprehensive. Those who boldly admitted their fears were, as a rule, quicker in reaching a smooth anaesthesia than those who suppressed it. Among the worst types were the man who had been long accustomed to a position of authority, the pampered woman, and the spoilt child. Among alcoholics, who required large doses and recovered consciousness very quickly, he distinguished two types: the cheery soul who drank to excess in company came up smiling for his anaesthesia, and though he might be noisy during induction, once "under" he slept like a babe; on the other hand, the alcoholic who drank because he lacked moral courage to resist exhibited the usual nervous signs extending far into anaesthesia. Tobacco fiends often had an irritable cough reflex, necessitating an unusual depth of anaesthesia. Drug addicts, he believed, were very refractory. Anaemia, fever, exhaustion, and shock promoted an easy anaesthesia, but the margin of safety was

¹ H.M. Statutory Officer, 80, Chichester Street, Belfast. (2s. 6d.)

smaller. Fat had been described as the surgeon's worst enemy, and it could hardly be called a friend of the anaesthetist. Pathological conditions liable to cause sudden death were always possible factors prejudicing anaesthesia.

The anaesthetist himself could bring to bear on anaesthesia stage management, judgement, and personality. As for the first of these, rest before anaesthesia was frequently not long enough, but the patient should also be given some mild mental occupation, such as an easy crossword puzzle. A man should not be "knocked off" his usual tobacco and alcohol the night before anaesthesia; this would only make him miserable and irritable. Stomach tubes, enemas, purgatives, and starvation might sometimes be necessary, but were very likely to exhaust and distress the patient. Silence or taciturnity was not a virtue in the anaesthetist. It did not matter much what he said to the patient, but he should say something, partly to create an idea and partly because most people derived comfort from a friendly voice on such occasions. Hearing returned early, and an assurance that all was well, spoken directly into the patient's ear, penetrated his understanding even though he was still apparently unconscious; if this was so, it was likely to help the onset of natural sleep. For comfort the patient should be allowed to have as many pillows as he liked, and to assume any position within reason; he could be placed in the required position when unconscious. It was preferable to let the patient hold the nurse's hand rather than the reverse, as the holding of the patient's hand by another was liable to be interpreted as a feeling of restraint. Judgement in the choice of dosage of anaesthetics would obviously affect anaesthesia, but that was outside his scope in this address. The anaesthetist's personality, a vague but important factor, might affect the patient profoundly. The "anaesthetic personality" might take a long time to develop. The secret was probably the gift of seeing things from the patient's point of view. The patient should not be approached with set phrases; rather should the art of making an appropriate remark at the proper moment be cultivated. If the anaesthetist did succeed in impressing his personality, a nurse by her encouraging or deprecatory allusions might do much to augment or wipe out entirely his good efforts.

The surgeon exerted a powerful influence on the anaesthesia. On occasion surgeons had been known to hurry induction, or even bluff the anaesthetist into allowing the operation to start before the patient was ready, a procedure which it might be difficult for a junior anaesthetist to oppose. Fortunately, however, most surgeons realized the importance of waiting for the anaesthetic balance. As for the operation itself, pulling, tearing, and stretching affected anaesthesia more than cutting with a sharp knife. They all knew that upper abdominal reflexes were more powerful than pelvic; that a total gastrectomy would disturb more than removal of a lipoma; that operations involving much haemorrhage would call for a marked reduction in dosage, an easy matter with inhalation methods, but not so simple with intravenous or rectal therapy. Menstruation was of importance in this connexion. In most cases it was a question of whether the patient minded putting up with more trouble at that time, but in major breast operations it might be a very real added risk to anaesthesia. It was easy enough to pick up cut vessels, but quite another thing to control oozing, and the latter might be severe at such periods. The position of the patient might introduce undesirable complications, varying from difficulty in maintaining a patent airway to a fatality, as in faulty position for spinal anaesthesia. On the other hand, position might facilitate anaesthesia by making operative measures easier. In empyema and such operations an intelligent and willing dresser was preferable to any mechanical arm rest, offering as he did much greater relief to the unaffected side of the chest from the considerable weight of the upper arm. The Trendelenburg position mostly made for safety and ease of anaesthesia, but might cause considerable respiratory embarrassment in obese subjects under full narcosis. The rolling of the

patient from side to side after deep anaesthesia or severe operation, to apply a many-tail bandage or remove the ambulance canvas from the bed, might cause profound depression. It was easy to lift the patient, like a horizontal poker, dry him, put on the binder, and remove the canvas, but it took three people to do it. The time factor in anaesthesia was also important. It was mostly held that about 9 a.m. was better for the patient than the small hours of the morning. The optimum time for anaesthesia in cases of severe trauma required insight and judgement if the best results were to be obtained. The length of time spent on any operation and its effect on anaesthesia was a very variable factor. In the case of a healthy patient subjected to, say, a varicose vein operation, it mattered little whether anaesthesia lasted for half an hour or, as in one case, three and three-quarter hours. But time in many cases might be very important. With wartime multiple gun-shot wounds the consensus of opinion favoured two, three, or even four surgeons working on the same patient at the same time. Another very difficult time problem was presented when the patient steadily got worse under anaesthesia. A pause for recovery during operations involving very severe hurt might be the means of making a successful termination possible. Here Dr. Crampton gave an analogy from the boxing ring, where the pugilist, severely punished in one round, might, after the brief pause, come up with astonishing vigour in the next round. Finally, Dr. Crampton mentioned the value of punctuality. Delay might have a very adverse effect on anaesthesia. A patient, keyed up to the ordeal, might be expecting the operation at 2 o'clock, and some form of premedication, perhaps, had already been administered, when the nurse broke the news that the surgeon had been delayed and could not operate until 5 o'clock. The food for the patient had been timed in view of the earlier hour, and it was now too late to give more. The premedication effect would wear off, and the victim would have to screw up courage all over again. Such eventualities militated against that ease of body and mind which made for a smooth anaesthesia.

SILICOSIS

At a pathological meeting of the Liverpool Medical Institution held on October 25th, with the president, Dr. J. MURRAY BLYTH, in the chair, Dr. W. E. COOKE read a paper on modern views on silicosis.

Dr. Cooke dealt with the necessity of reconsidering the terminology in the many conditions at present included under the title of "silicosis." The causative factors were considered in the light of the recent work of W. R. Jones and W. Tideswell. The effect of size of the grain on the solubility of SiO_2 , the size of lung alveoli, the presence of large particles of insoluble minerals such as asbestos fibres and fusain spicules in asbestosis and coal-miners' lung, and the production of the curious bodies in these diseases and in normal lungs were considered. Photomicrographs of potash feldspar undergoing metamorphosis into secondary white mica and sericite and coal-measure shale and mine dust demonstrating the presence of sericite and quartz grains were shown. Badham and Taylor's views on sillimanite in the production of silicosis in New South Wales, and their chemical analyses of the lungs of various workers, were considered and compared with the lung analyses of other observers. Examination of the lung sections by polarized light and the results of the repetition of Watkins-Pitchford and Moir's work in this connexion were given. The conclusions arrived at were that the balance of probability, on the insufficient data of to-day, pointed to the various forms of pneumoconiosis being due to chemical rather than mechanical action, and until the silicates (sericite, sillimanite, and asbestos) and the various forms of silica (quartz, chert, flint, etc.) were isolated in a pure state and investigated in regard to their solubilities in plasma and the tissue reactions to their presence, no progress in the aetiology of the disease was possible.

In the discussion which followed, Professor J. HENRY DINTZ said that he appreciated the scientific quality of Dr. Cooke's communication and the importance of his mineralogical observations. He himself had been im-

pressed by the case made out by W. R. Jones for sericite in the examples of silicosis with which the latter had worked. It was difficult to clear the mind of a doctrine which hitherto had been acceptable and to approach the problem entirely on its merits; and Jones's work was therefore subjected to a good deal of prejudice. If the sericite theory were weighed against the silica theory it had to be admitted that sericite was present in the lungs in question, and in large amounts. The speaker was not competent to question the identification of the mineral, and had to accept the statement of the mineralogist on this point. It was stated that sericite was less stable than quartz, and it seemed perfectly reasonable to accept the view that it could cause the fibrosis. At the same time it was apparent that in other situations silicosis (without quibbling over nomenclature) arose without the presence of sericite; an example was to be seen in the recently published cases of siderosilicosis of Professor M. J. Stewart, in which sericite could not be demonstrated. The theory put forward by Jones was well sustained by his observations on the distribution of silicosis in relation to distribution of sericite; this part of his work was unquestionably impressive, although the speaker would emphasize the pitfalls encountered in accepting loose clinical statements as to the presence or absence of silicosis in any given industry or mine which were not substantiated by pathological findings. Experience in the South Wales coalfield had emphasized this.

Dr. C. O. STALLYBRASS referred to the radical alteration in views with regard to silicosis which have taken place in the past ten years, largely as the result of Dr. Cooke's work on asbestosis. Dr. Cooke was not only a skilled pathologist but also had exceptional knowledge of microscopy and mineralogy, which enabled him to deal with this borderline of science.

ACUTE CHOLECYSTITIS

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on October 26th, Mr. SETON PRINGLE took as the subject of his presidential address "Acute Cholecystitis."

Mr. Pringle called attention to the fact that the clinical picture of acute cholecystitis was generally unmistakable, and discussed the differential diagnosis from acute perforation of the duodenum with extensive extravasation, acute perforation of the duodenum with slight extravasation, acute pancreatitis, and acute inflammation of a high-lying appendix. In discussing the pathology he called particular attention to the facts that the cystic duct was commonly obstructed by a stone, that the wall of the gall-bladder was usually greatly thickened and fibrosed, and that, although perforation of the gall-bladder occurred in some 15 per cent. of cases, in only about 1 per cent. did free peritonitis result, as in all other cases sufficient time had elapsed for the gall-bladder to become so surrounded by adhesions that a pericholecystic abscess only resulted. Mr. Pringle laid particular stress on the rarity of free peritonitis occurring in gall-bladder cases as compared with acute appendicitis. He dealt at some length with the question as to the best time for operation, and pointed out that the literature showed an increasing number of surgeons who advocated immediate or early operation. In conclusion, he stated his own views, which were that immediate operation was only justified in very acute cases, showing marked toxæmia, very severe pain, persistent vomiting, and rigidity. He was satisfied that the great majority of cases would settle down and allow a safer and more complete operation to be carried out in eight to ten days. He did not approve of further postponement, because many perforations of the gall bladder, with the development of pericholecystic abscesses, took place without definite clinical manifestations. As regards the actual operation, he considered cholecystectomy the operation of choice, and said that cholecystostomy should be reserved for those very toxic or jaundiced patients in whom only a minimum of interference was permissible, and where the gall-bladder was particularly inaccessible.

Mr. R. ATKINSON STONEY said that it was occasionally difficult to make a diagnosis between acute cholecystitis and acute appendicitis, and mentioned in this connexion a case where a very large gall-bladder attached to a prolapsed Riedel's lobe had caused a tender mass in the right iliac fossa. Sometimes there might be a combination of conditions present, as evidenced by a case which developed a pancreatic pseudocyst after drainage of an inflamed gall-bladder; acute pancreatitis and acute cholecystitis sometimes occurred together. The question of the time when to operate was of great importance; it was, he thought, safe in each particular case to wait and see what was going to happen, and during the waiting period it was usually possible to improve the patient's condition by giving saline.

Mr. T. J. D. LANE thought that the anaesthetic was of the utmost importance in cases of acute cholecystitis. He did not see any point in postponing operation for a few days, and thought that at the end of two or three days the patients were in a much worse condition than they were twenty-four hours after the attack. He also asked why Mr. Pringle removed the gall-bladder from the fundus downwards. Mr. H. STOKES thought he would not operate after a first attack of acute cholecystitis. He would like to know how much a gall-bladder could recover. An appendix could recover after an acute attack in a fortnight to what was macroscopically a normal state, and he thought that if a gall-stone were passed the gall-bladder would also return to normal. The diagnosis was sometimes extremely difficult, and he had recently found a perforated gall-bladder in a patient who had been treated medically for duodenal ulcer.

Dr. R. W. SHAW said that in many cases the use of an intratracheal tube made the operation much easier. He thought that high spinal anaesthesia in combination with nembutal orally was very satisfactory for any high abdominal operation. Mr. H. MEADE mentioned a case in which he had found the gall-bladder on the left side of the pelvis, and the seat of an early carcinoma. He felt that in acute cases operation should not be delayed. One sometimes came across patients with chronic heart disease, and in these cases it was better to give digitalis to the patient before operating. Mr. A. B. CLERY said that in acute cases if he had to operate, he merely drained the gall-bladder, usually with a local anaesthetic, but he only operated on an acute case when it was absolutely necessary to do so. He thought that perforation was more likely to occur in elderly patients. The reason in most cases for operating early was because there was a doubt about the diagnosis.

Mr. PRINGLE, in reply, said it was very difficult to get the best anaesthetic. Usually the old gas, oxygen, and ether sequence satisfied him. He had no doubt that cholecystectomy and not cholecystostomy was the operation of choice. He always attacked the fundus first, and found this very satisfactory, but in a chronic case it was easier to remove the gall-bladder from below upwards. He did not interfere with, or look at, the common duct unless, before operation, there was something definitely pointing to the fact that it contained a stone. He thought it was very rare to get acute suppurative cholecystitis and a stone in the common duct. The whole crux of the question was the time at which to operate. He only operated as an emergency when there were general symptoms and considerable toxæmia.

The ninth congress of the Far Eastern Association of Tropical Medicine was held in Nanking from October 2nd to 8th, and was attended by a large number of representatives and delegates from the countries of the Pacific, from India, and from the United States. There were ten scientific sections, of which six were devoted to plague and cholera, malaria, leprosy, parasitology, bacteriology, and public health and quarantine, and two round-table discussions on plague and cholera respectively. Three interesting tours were promised in addition to numerous social functions. The acting president of the congress was Dr. J. Heng Liu, the other members of the Executive Committee being Drs. F. C. Yen and H. P. Chu (Shanghai) and Dr. P. Z. King (Nanking).

CORRESPONDENCE

Election to General Medical Council

Representation of Scotland

SIR,—We, the undersigned, having nominated our present representative, wish to appeal on his behalf to all members of the profession resident in Scotland. Sir Norman Walker holds at present the high position of president of the Council, an honour never before attained by a direct representative. Sir Norman, from his early experience in general practice, knows well its difficulties, even its hardships. Since leaving it for the specialty of dermatology he has been unremitting in the work he has done in medical administration, and during the war, as chairman of the Emergency Committee and as Commissioner for Medical Services for Scotland with the Ministry of National Service, did most important work for the community. After the war he was selected by the General Medical Council and sent to India to report upon the conditions of medical education; a piece of work for which he received the honour of knighthood in 1923; and when, five years later, it proved necessary to review the work then inaugurated Sir Norman again undertook the investigation. For thirteen years he was chairman of the Examination Committee, as also of the Business Committee, and the impress of his work was such that on the retirement of the late Sir Donald MacAlister he was elected to succeed him. It is not for us to say to the Council who should be their president, but we in Scotland should see to it that Sir Norman is there at their service.

We therefore, Sir, through your courtesy, would ask our fellow countrymen to support Sir Norman's candidature.—We are, etc.,

ANDREW ALLISON, M.B., Ch.B., B.Sc.,

October, 1934.

* As we go to press we learn that Sir Norman Walker has been returned unopposed as direct representative for Scotland on the General Medical Council.

Representation of England

SIR,—May I, through your columns, return thanks to my colleagues on the *Medical Register* for re-electing me to be one of their direct representatives for England and Wales upon the General Medical Council. I shall hope to be of service.—I am, etc.,

London, W.1, Nov. 2nd.

N. BISHOP HARMAN.

Medical Benevolence

SIR,—Dr. A. J. Hawes's letter, in your issue of October 20th (p. 745), mentions what has always been the wish of my committee—namely, that a suitable representative of the Fund should be appointed in every district.

It is acknowledged that whatever success we may have achieved in recent years from a larger subscription list

(in 1923, £4,758; in 1933, £11,856—an increase of approximately £7,000) has been due mostly to the energies of the honorary local secretaries, who have volunteered for the work. We have now 121 honorary local secretaries in England, Scotland, and Wales. Personally, I do not believe that there is any apathy in the profession as regards willingness to help our less fortunate brethren, but unless we can secure the help of volunteers, who will win over the obdurate and recalcitrant non-subscribers, we have no alternative but to issue printed appeals from the London office in order to make our work known.

On behalf of the committee, I issue this invitation through your columns to any of your readers who are willing to help us by taking an active part as honorary local secretary for the district in which they practise. The work required is not overwhelming. Such clerical work as the writing of letters in duplicate and the posting of appeals is undertaken by the clerical staff in London. The actual duty of the local secretary is to ensure, by a personal touch, that none of his colleagues in his district may be able to say that he is in ignorance of the existence of the Royal Medical Benevolent Fund, or that he has never been invited to subscribe to it. I hope that this formal invitation will lead to many helpers coming forward, so that we may have double the number of local secretaries at the end of this year to enable fresh efforts to be made in 1935.—I am, etc.,

D'ARCY POWER,

London, W.1, Nov. 6th.

Chairman of Committee, Royal
Medical Benevolent Fund.

SIR,—I feel I must enter a gentle protest against the last paragraph of Dr. Harnett's letter (*Journal*, November 3rd, p. 837). After telling us of the fine way in which his Division has responded to his energetic efforts, he says that the Association is so busy with schemes for socializing the profession that it has little time to devote to the needs of medical charities, and goes on to say it should "urge a little more vigorously upon the Divisions the necessity of having an active charities secretary."

Within my own personal knowledge during the last ten years the Charities Committee has persistently impressed upon the Divisions the necessity of having a charities secretary. We tried all sorts of appeals, and undoubtedly the Association has made considerable progress since the time when it first took the medical charities up seriously. In various communications to the Divisions I made my own opinion perfectly clear (and I know my successor has done the same)—namely, that no Division can call itself properly organized and claim to be doing its duty to the profession and to the Association unless it has an active charities secretary. Wherever there has been such a secretary good results have followed.

As a member now of the Case Committee of the Royal Medical Benevolent Fund I spend a painfully interesting afternoon every month in going with my colleagues through the applications for assistance. We do our best, but we often feel that our best is only able to keep the recipient just above the starvation line. I wish every member of our profession could spend an afternoon with us; they would go away sadder persons, but determined to be subscribers and to enlist others. Like your correspondent from Scotland, I am convinced that the profession is quite able to provide for its own poor, and that in the Royal Medical Benevolent Fund it has excellent machinery for that purpose. From long experience I know that no words of mine are likely materially to alter the curious apathy of a large number of doctors. The situation is discreditable to us as a profession, and it has always been a mystery to me, because I know that the average doctor is a warm-hearted person, peculiarly

open to the appeal to his heart and to his pocket when the individual case comes to his notice. The difficulty is to arouse his imagination, and make him see that pathetic body of people, very like himself and his own wife and children, who have no other source of help than the charity of their professional brethren.

In the future I believe that the efforts which the B.M.A. is making to induce the general practitioner to insure himself against the contingencies of life will greatly lessen the claims on the benevolence of the profession, but in the meantime the need is there, and it is very great.—I am, etc.,

London, W.1, Nov. 2nd.

ALFRED COX.

After-treatment of Empyema

SIR,—I imagine that most surgeons who take an interest in the after-treatment of the empyemata that they may operate upon must agree with Mr. Denis Browne in his contribution to the *Journal* of November 3rd. To state an empirical date for the removal of empyema tubes is quite as irrational as to assert that a tuberculous hip should be immobilized for six or twelve months or three years. I think that very many records and statistics relating to the treatment of empyemata are untrustworthy, because so often the healing of the sinus in the chest wall is taken as the criterion of cure.

A few weeks ago I saw a woman who had a "successful" operation for an empyema twenty years before. The wound healed, and she was well for thirteen years, when she "felt her chest filling up again." The cavity was again drained and the sinus allowed to close, and since then the operation has been repeated twice at intervals. When I saw her there was no drainage; she simply complained that she could feel the fluid accumulating. At operation 1½ pints of thick pus were liberated. The walls of the cavity were found to be very tough and fibrous, obviously the original one which had never been obliterated. The discharge rapidly abated, and I am sure that if I were to remove the tube now the wound would heal again as on the previous occasions. There is also no doubt that the surgeons who performed the previous operations were satisfied that she was cured.

I am convinced that the only reliable indication that an empyema is healed is to be found in the x-ray examination after the injection of an opaque substance into the sinus, and not until this shows complete obliteration of the cavity deep to the ribs should drainage be removed. Filling up the cavity with Dakin's solution and measuring the amount contained is useful and inexpensive, always provided there is no broncho-pleural fistula, but this only gives an idea of the size and not of the shape and boundaries of the cavity. Sometimes it is very important to be aware of the way in which an empyema is closing in, as, for example, in the multilocular variety or in those large empyemata where the apex is involved and where there is a tendency for this region to become shut off from the site of drainage and to be left as a residual cavity. The value of repeated x rays with an opaque substance cannot be exaggerated.

To minimize expense I use the irrigation method in the early stages when the cavity is large, and then resort to x rays when the irrigation chart shows that the capacity is suitably diminished. For this purpose I have used 20 per cent. sodium bromide solution without any ill effects, but I have discontinued this because the shadow cast in the lateral view is not definite enough. I now use iodolol, and find it just as efficient as lipiodol and less expensive. I think globules are only formed if a small quantity is used in a large cavity. I shall welcome Mr. Denis Browne's cheap emulsion.—I am, etc.,

November 2nd.

P. R. ALLISON, F.R.C.S.,
Surgical Tutor and Registrar, The
General Infirmary at Leeds.

X-Ray Examination of Empyema Cavities

SIR,—One is indebted to Mr. Denis Browne for his article on this subject (*Journal*, November 3rd, p. 807), but I would like to emphasize certain points which I have found of special importance while working on the surgical side of the Brompton Hospital. One obtains here considerable experience of chronic empyemas—that is, empyemas which have not healed after the ordinary period of weeks or months, but have persisted for months or years. In the past year I have seen fifty-eight patients of this sort treated, and this excludes tuberculous pyopneumothoraces.

The most striking thing is that easily the largest number have been brought about because the original drainage tube was taken out at the wrong time—usually too soon. It is a patent fact that the teaching at universities to students of when to remove the tube in an acute empyema is sadly lacking. Here it has been known for many years that drainage should cease when the empyema cavity is obliterated. As in all septic cavities, this only occurs by the fibrosis and healing together of the cavity walls. A dogmatic time, or the nature of the discharge, are quite useless as criteria, and the fact that there is no cavity at the end of the short track can be the only indication. In the early stages, of course, where the cavity is still large, the amount of fluid it will hold is easily determined, and indicates its size, but later, when there is perhaps a small cavity with a long sinus, we have found x rays after the injection of lipiodol perfectly satisfactory to delineate the outline, and have used it as a routine for many years. Where a large quantity is necessary a barium emulsion can be used with perfect safety, and is, of course, cheap.

I would like to draw attention to three details of technique. (1) The opaque fluid should be run in with the sinus opening at the highest point. (2) After plugging the opening tightly a metal ring, as a marker, is placed over it. (3) Lateral as well as antero-posterior x-ray views are essential, and erect as well as recumbent views may be necessary if the cavity is large.

It can only be when the essential rules for removing tubes in empyemas are fully understood that numberless patients can avoid the long ill-health and frequent operations that become necessary when an empyema becomes chronic.—I am, etc.,

A. BRIAN TAYLOR.

Brompton Hospital, S.W.3, Nov. 5th.

Treatment of Haemoptysis

SIR,—The use of Congo red in the treatment of haemoptysis and other forms of haemorrhage, as described by Drs. Morlock and Scott Pinchin (*Journal*, October 27th, p. 762) is of very considerable interest and worthy of a more widespread application.

Congo red has been extensively employed by Bennhold, Bookman and Rosenthal, Strasser, and others in the diagnosis of amyloid disease.

Some years ago I made an investigation into this test (*Lancet*, February 20th, 1932, p. 391) which necessitated intravenous injections of the dye into forty-five patients, mostly children. A 1 per cent. solution was used and the dosage calculated on the basis of 0.25 c.cm. per kilo body weight—that is, from 6 to 12 c.cm. in children and 16 c.cm. for a 10 st. adult. No after-effects of any kind were noted and rigors were entirely absent. This, I think, was probably due to the observance of two points which are stressed by the Continental workers: (1) the use of Grubler's Congo red, which is free from such commercial impurities as lead and arsenic; and (2) the fact that all solutions were used within twelve hours of being made. Strasser observed that solutions more than

twelve hours old tended to produce shivering attacks and pyrexia. There was a notable reduction in the clotting time of the blood after injection of the dye. In fact, this was sufficiently marked at times to create some difficulty in the technique of the amyloid test.

More recently I have injected from 12 to 16 c.cm. of Congo red into a smaller number of adult cases of amyloid disease, also without the slightest ill effect. The opportunity to use the dye in haemoptysis has occurred only once, but the response was entirely satisfactory.—I am, etc.,

Standish, Lancs, Oct. 36th.

J. EDGAR WALLACE.

SIR,—My more limited experience confirms the statement of Drs. H. V. Morlock and A. J. Scott Pinchin in their interesting article on haemoptysis regarding the value in treatment of 10 c.cm. of a 1 per cent. solution of Congo red given intravenously. This treatment is, as they point out, comparatively unknown in Great Britain. Some two and a half years ago the well-known phthisiologist Professor L. Brauer, medical director of the Eppendorf Hospital, Hamburg, told me that of all the drugs tried in his wards in cases of haemoptysis 1 per cent. Congo red solution given intravenously had been found the most effective. I have employed for convenience a proprietary preparation, haemostaticum, made by Nordmarkwerke A. G., Hamburg. I have always injected haemostaticum very slowly, and have never seen any rigor or untoward reaction. Drs. Morlock and Scott Pinchin rightly point out the necessity of not employing a solution of Congo red stronger than 1 per cent.

I hope their article will result in a more widespread use of what appears to be a definitely helpful medical treatment of haemoptysis.—I am, etc.,

Montana, Switzerland, Oct. 29th.

HILARY ROCHE.

SIR,—I am interested to note that Dr. H. V. Morlock and Dr. A. J. Scott Pinchin, in their article in the *Journal* of October 27th (p. 762), discuss the use of intravenous injections of Congo red in the treatment of haemoptysis. They state, however, that the injection of 10 c.cm. of a 1 per cent. solution of Congo red is often followed by a definite rigor. I have used as much as 10 to 18 c.cm. of a 1.5 per cent. solution of Congo red intravenously in over sixty cases for the estimation of blood volume, and have not observed rigors in any of these cases. The solution of Congo red used is made up with triple-distilled water and filtered through glass wool. I would suggest that the use of triple-distilled water in the preparation of the dye is an important factor in the prevention of rigors.—I am, etc.,

Liverpool, Oct. 31st.

JULIUS LIBMAN, M.D.

Blindness After N.A.B.

SIR,—Mr. F. Juler's account of a case of blindness after N.A.B. (*Journal*, November 3rd, p. 809) will be of particular interest to all those who are daily using anti-syphilitic drugs.

On admission his patient was found to have a positive Wassermann reaction and an aortic systolic murmur. In view of this and subsequent findings it seems reasonable to suppose that the syphilitic process was not confined to any one blood vessel, but that other arteries, including those of the optic nerves, were also involved. Optic atrophy following upon the injection of trypanamide is quoted, but this rarely if ever results when the eye is healthy.

It is generally recognized that arsenobenzol preparations, even in small doses, are dangerous in cardiovascular

syphilis, as further damage to the arterial walls may be brought about. Fortunately, the administration of full doses of N.A.B. in such cases must be almost as rare as the occurrence of blindness after their use.—I am, etc.,

November 3rd.

JOHN A. BURGESS,
V.D. Officer, City of Stoke-on-Trent.

Local Treatment of Coryza

SIR,—It is to be hoped that the *laissez-faire* attitude towards the common cold adopted by many individual sufferers, and advocated by Colonel W. C. Spackman in your issue of November 3rd (p. 835), will not become prevalent. Surely few will doubt that the results of a fatalistic inertia are seen in too many instances to be for the patient an unwelcome train of complications, and for his neighbours many contact infections. As well laud the virtue of a streaming cold in the head as a preventive of bronchitis as an active warfare on one frontier as a guarantee of peace on others!

Contrary to Colonel Spackman's view that "we are unable to cut it short by local means," further trial of the simple methods I advocated in the *Journal* in 1932 (March 5th, p. 449) has convinced me of their efficacy. A high percentage of colds can be stopped in an hour or two of the onset, or, in severer types, changed from a ten-day to a one- to three-day type, if the person affected, within an hour of the onset, will gargle with really hot water for a minute or two every fifteen to twenty minutes, and will immerse the hands and arms (and feet also, if chilled) till reddened in hot water. This alone will abort many colds. Adjuvants are hot drinks, a mild erythema dose of ultra-violet light, and "mistol," "orargol," or other antiseptic sprays, douches, or gargles.

A further valuable local remedy is the "anti-coryza spray," a local immunity vaccine (with antiviral) from the Pickett-Thomson Laboratory, and marketed by the Genatosan Company. I have seen a number of cases in which this has been of benefit, both as a preventive and as a curative agent. References to local immunity in the prevention and treatment of coryza and of suppurative rhinitis are given by Besredka in his *Antivirustherapie* (1930, p. 80).

For those distressing colds which commence with fever and depression and pain in the trachea, felt just above the manubrium, a new remedy available is the ultra-short-wave diathermy. In one patient whom I saw lately with this onset a probable bed illness of ten days or so (from previous experiences) appeared to have been converted into a trifling interruption of the usual health. One ten-minute treatment with a six-metre wave-length relieved the pain immediately and the fever subsided; a good night followed a second evening application; next day there were no signs of "cold." On the following day a slight relapse with malaise and tracheal pain was promptly relieved after a similar treatment. For this tracheal type, and probably for acute laryngitis, some cases will have speedy relief after short-wave diathermy.—I am, etc.,

London, W.1, Nov. 3rd.

J. H. DOUGLAS WEBSTER.

Bacteriological Examination of Milk

SIR,—The scheme of the Milk Marketing Board for the supply of milk to school children is now in operation. It has been decided that all milk supplied to schools shall be the jurisdiction of the London County Council shall be "pasteurized," and in accordance with the arrangements made between the medical officers of health of the metropolitan boroughs and the County Council, samples

are being taken for chemical analysis and bacteriological examination. It is suggested that the procedure to be adopted in the event of adverse reports being received upon these samples shall be to issue a warning in respect of a first unsatisfactory sample and to withdraw the approval of the source of supply should a second sample be reported not to conform to the prescribed standards.

The Milk (Special Designations) Order, 1923, lays down certain conditions under which graded milks may be sold, and these include a requirement that, on a sample being taken after pasteurization and before delivery to the consumer, the milk shall be found to contain not more than 100,000 bacteria per cubic centimetre. The Order provides, further, that a licensing authority, if it is satisfied that any of the conditions upon which a licence is granted are not being complied with, may suspend or revoke the licence.

It is my considered opinion that most of the reports now received with regard to the bacteriological examination of milk are unreliable, and I suggest that, should the above procedure be carried out, serious injustice may be done. The question of sampling and examination of graded milks is one to which I have given considerable attention in the past, and, in support of my view, I would draw your attention to the following facts:

Some time ago I became dissatisfied with the results of the examination of samples, which, at that time, were being submitted to one of the largest laboratories specializing in this work in the country. I therefore decided to send test samples to another laboratory.

Two churns of milk were selected upon delivery at each of two hospitals in Hammersmith, and duplicate samples taken from each. The same methods were adopted for each sample. Bottles, sterilized under exactly similar conditions in the laboratory, were used for each of the samples. They were immediately packed on ice, and four were submitted to the usual laboratory and four to another well-known institution. Sample "A" was reported by one laboratory to contain 39,880 bacteria per c.c.m. (well within the prescribed limit), and by the other 144,000 per c.c.m. (nearly 50 per cent. above the legal maximum). The other three reports all showed similar variation.

Recently I have had further tests made, with startling results. A quart bottle of pasteurized milk was taken and, after being thoroughly shaken, divided into six parts. Sterile bottles were used and every precaution taken during the division. Two of these bottles were submitted to each of three laboratories. The following table gives particulars of the reports received:

No. of Sample	Bacteriologist	Temperature on Arrival	No. of Bacteria per c.c.m.	Presence of B. coli (48 hours)			
				1/10	1/100	1/1000	1/10000
1	No 1 laboratory	15° C.	9,270	+	-	-	-
2	No 1 "	15° C.	14,300	+	-	-	-
3	No 2 "	15° C.	197,333	-	-	-	-
4	No 2 "	11° C.	3,400,000	-	-	-	-
5	No 3 "	16° C.	36,000	+	-	-	-
6	No 3 "	16° C.	47,000	+	+	-	-

It will be seen that one report gives a bacterial count of 9,270 per c.c.m., and another of 3,400,000 per c.c.m. for the same milk, and that the results obtained by one laboratory vary from 147,000 to 3,400,000. Other tests have been made, and the above figures are typical of the results obtained.

In view of these facts I think it must be agreed that to withdraw a licence upon such unreliable data would be most unjust. In Memo. 39, *Feeds* the Ministry of Health sets out a suggested technique for the bacteriological examination of graded milks. If this is properly carried out the results should be reasonably comparable. I can only

assume that, in making their examinations, bacteriologists do not faithfully and carefully carry out the suggested procedure. Unless every stage, from the composition of media to uniform heating in the incubators, is standardized the results must vary.

There is one point in the Ministry's suggested technique to which I would draw attention. In paragraph 12 it is stated that the original sample and each dilution must be shaken twenty-five times, each shake being an up-and-down motion, with an excursion of about one foot. This shaking is, of course, to distribute the organisms in the sample evenly, and, secondly, to break up any bacterial aggregates which may have been formed. Most samples of graded milks are submitted to the bacteriologist in the bottle in which the milk is sold, and, as such bottles are usually entirely filled with milk, it is unlikely that any proper mixing is obtained by shaking, unless the milk is first transferred to a larger bottle. Again, the vigour with which the shaking is conducted may make an appreciable difference to the final count. I suggest that more uniform results would be obtained by the use of a mechanical shaker, working at a standard speed.

Reviewing the position as it now stands, I am of opinion that little value can be placed upon the reports received, and that, until a more standard practice is adopted by bacteriologists, both time and money are being wasted in submitting milk samples for examination.—I am, etc.,

J. B. HOWELL,
Medical Officer of Health.

Town Hall, Hammersmith,
W.6, Nov. 1st.

Whither General Practice?

SIR,—From what I hear around me I conclude that there must be many medical practitioners who deeply resent the fact that they are not permitted to attend their patients who enter the smaller hospitals and nursing homes; and I am surprised to hear that my medical friends have little expectation that a grievance, which is often shared by their patients, will be removed. Yet in many cases their patients enter these institutions solely because of the better nursing arrangements and facilities therein provided. Why, in these cases, the family doctor should be debarred from continuing his services, if he pays his visits at specified hours, is incomprehensible to me.

Surely it must be in the interest of the whole profession that the family doctor—the "backbone of the medical profession"—should not lose prestige in the eyes of his patients; and it must be to their disadvantage to be transferred to other local practitioners who lack his special knowledge and experience of their previous illnesses. It is, moreover, a regrettable fact that such a transfer of medical services occasionally leads to the patient changing his doctor after his discharge. Although this may be attributable to the usual commendation of their medical chief by a devoted nursing staff, local medical harmony is seriously disturbed.

Therefore it is not surprising to learn that it is the policy of the British Medical Association that, where possible, the family doctor shall be permitted to continue to attend upon his patients. But if this is so, may we be told what the B.M.A. is doing in the matter?

The problem of remedy is not insoluble. The solution is at the hands of the small medical staff of such institutions; and with the good will and loyalty common among medical gentlemen it can be solved very shortly. So I am loath to believe that an appeal by the B.M.A. to this end would fall upon deaf ears. But if this should happen in some few instances the appropriate action suggests itself.—I am, etc.,

London, N.4, Nov. 4th.

HENRY R. KENWOOD.

Concurrent Varicella and Herpes

SIR,—I read the letter of Dr. Fishman describing his case of concurrent varicella and herpes zoster, in the *Journal* of November 3rd (p. 836), with interest, as a similar case of mine, in a man aged 74 years, was published by you, together with two illustrations showing the rashes, in your issue of July 22nd, 1933. Since then several other cases of this pathological partnership have been described in the literature. Post-pituitary extract intramuscularly, in doses of 3 to 10 units per diem, has recently been used by some in treating cases of herpes zoster, and I would like to know if anyone has tried this in cases of varicella, in view of the fact that there is more than probably a close relationship aetiological between the two diseases.—I am, etc.,

Leicester, Nov. 4th.

F. A. E. SILCOCK.

Thrombosis of Internal Saphenous Vein

SIR,—In the *Journal* of July 28th Dr. A. S. Parkinson advocates the proximal ligation of the saphenous vein if possible in cases of thrombosis. But what is wrong with excision of the thrombus? An ex-major came to us limping, and with a history of varicose veins in the left leg. He told us that during the war a surgeon had offered to excise his veins, but he could never spare the time to lie up in hospital. On inspection a large thrombus was found. As he was a house friend I kept him in bed in my house for a week, but then he became restless. Being an active man, he did not like wasting his time in bed. So I excised the whole thrombus under local anaesthesia, after ligaturing the saphenous vein with catgut. I made an elliptic incision, cutting into healthy skin, as the skin over the thrombus looked dark and thin. He made an uninterrupted recovery, and was at work in the garden after a fortnight. He was especially pleased about the relief of pain, and it seems to me that the period of forced rest is greatly shortened by removing the whole thrombus. As the skin is usually adherent to the inflamed thrombus, and is thin and unhealthy at that spot, it is advisable to excise a large piece of skin with it. I had to put a pressure pad on, as there was a hollow where the thrombus had been, but this was completely filled up in a few months' time.—I am, etc.,

Sterkstroom, Cape, Oct. 8th.

S. J. D. ESSER.

Therapeutic Malaria and Haemoglobinuria

SIR,—Dr. C. B. Bamford, in his article (*Journal*, October 27th, p. 764) on haemoglobinuria seems to us to go rather too far in one or two points of his discussion of the matter.

From the details recorded we ourselves would have had, we think, a little doubt about this being a case of blackwater fever, in spite of "the appearance of most of the characteristic features of the disease in the usual sequence," and for the following reasons:

1. Investigation of more than a man's previous history is needed to exclude latent malignant tertian malaria.

2. Unless very severe, haemolysis occurring in any case of quinine-treated malaria—and particularly one in which subtertian infection was not proved—would, to our mind, first raise the question of toxic action of quinine rather than one of true blackwater.

3. This patient seems to have had a haemolysis of gradual development, without bilious vomiting or pain, and four days after the commencement of the haemolysis his blood haemoglobin content was hardly disturbed.

4. Although the man had had no previous haemoglobinuria it seems unfortunate that his serum was not tested, after chilling, against his own and other erythrocytes.

Incidentally, in spite of more modern opinion, Dr. Bamford will find in at least one textbook—the sixth

edition of Sir Patrick Manson's *Tropical Diseases*—expressions of this kind:

"It is usually in those who have suffered from subtertian infection—more rarely from tertian or quartan, or from dysentery, or who are run down from any cause—that blackwater occurs." (Italics ours.)

—We are, etc.,

Dilating the Cervix in Placenta Praevia

SIR,—Dr. A. J. Hawes, in his article on the death of Mauriceau's sister (*Journal*, October 27th, p. 783), expresses some apprehension as to the safety of "manually dilating a cervix with a placenta attached to it." Having had a considerable experience of cases of placenta praevia—over a score—without a maternal death, I can assure him that the careful obstetrician need have no fear of inflicting damage. If placenta is detached from uterine wall as far as the finger can reach, the cervix will dilate up readily under gentle but firm stretching by the fingers without showing any tendency to laceration. The whole hand should then be passed into the uterus—it is presumed that the membranes have been ruptured early—the child turned and slowly delivered. It is true that very great prior loss of blood may entail more rapid delivery, but even then I have never known damage to occur.—I am, etc.,

Harston, Cambridge, Oct. 30th.

W. J. YOUNG.

Differential Diagnosis of Chronic Rheumatic Disease

SIR,—It is often very difficult, yet a matter of great moment, to decide whether a case is one of muscular rheumatism, nodular rheumatism, neuritis, or incipient arthritis, nor can radiograms be relied on to exclude arthritis in the early stages. Sciatic pain may be referred from a spondylitis or from a fibrositis; chronic stiffness and pain in the neck may be muscular or due to a cervical arthritis; a swollen finger-joint, though technically an arthritis, may be an entirely transient lesion which clears up leaving no trace, or it may be the forerunner of a severe generalized infection leading to crippling osteoarthritis. Again, it is not always easy to decide between a true rheumatoid arthritis and a very active osteoarthritis.

A pathognomonic sign of an early or threatened osteoarthritis would be of great value. Such a one, I believe, is to be found in the knee-joint. When osteoarthritis is present anywhere in the body, or even only threatened, it seems to be an absolute rule that the cartilaginous surfaces of this joint show some erosion. By pushing the patella to and fro transversely over the condyles of the femur when the leg is straight and relaxed, we are rubbing two cartilaginous surfaces together. To the observer the sensation imparted in the normal knee-joint is one of velvety smoothness, whereas in cases of osteoarthritis this is replaced by a faintly gritty sensation, or a "knock," which is quite obvious to the practised hand. It does not follow that patients make any complaint of the joint. Frequently they are unaware of the abnormality, and the surfaces, though rough, are quite insensitive. Typical primary rheumatoid and non-articular arthritis are excluded by a positive, osteoarthritis by a negative, sign. This has now been recorded in many hundreds of cases at the Chatterhouse Rheumatism Clinic and in private, and so far has never given a wrong indication. I therefore venture to bring it to the notice of members of the British Medical Association for their trial, and later, I hope, for their endorsement.—I am, etc.,

H. WARREN CROWE, D.M., B.Ch. Oxon.

London, W.1, Nov. 1st.

B.C.G. Vaccine

SIR,—I am grateful to Dr. G. Gregory Kayne for drawing my attention to the dilution of the parenteral B.C.G. (BCG-SC) issued by the Institut Pasteur, Paris (*British Medical Journal*, October 27th, p. 791). I was working in America with a strength of 0.1 mg. in 0.1 c.c.m.; this is a convenient quantity for an intradermal injection, and can be quite accurately measured in a Mantoux syringe. I was under the impression when I wrote my book that this was the strength issued by the Institut Pasteur.

Since reading Dr. Kayne's letter I have written to Paris to see if such a strength could be specially made for intradermal use, or whence it could be obtained; I will inform him as soon as any arrangement has been reached.

Instructions that the vaccine should be used within ten days of its preparation are issued with each ampoule of B.C.G.—I am, etc.,

Henley-on-Thames, Nov. 3rd.

K. NEVILLE IRVINE.

"The Angel of Death"

SIR,—When I read Mr. G. Gordon-Taylor's excellent address on "Bad Surgical Risks" in your issue of October 27th I realized that between us we had very completely destroyed the famous passage from the speech of John Bright on the Crimean War, which runs as follows: "The Angel of Death has been abroad throughout the land; you may almost hear the beating of his wings."

I quoted from memory at the Association of Surgeons meeting in Birmingham, and in doing so unconsciously paraphrased the quotation to make it applicable to my subject. The words I actually used were as follows: "The Angel of Death is hovering o'er them, so close that they can almost hear the fluttering of his wings." I think the paraphrase was justified, though I admit that the use of the word "fluttering" instead of "beating" robs the passage of much of its power and beauty. For the final form as given by Mr. Gordon-Taylor I must disclaim all responsibility.—I am, etc.,

Manchester, Oct. 30th.

GARNETT WRIGHT.

Universities and Colleges**UNIVERSITY OF OXFORD****Radcliffe Prize**

The next award for the Radcliffe Prize will be made in 1935. The prize, which is of the value of £50, is awarded by the Master and Fellows of University College, Oxford, every second year for research in any branch of medical science, comprised under the following: human anatomy, physiology, pharmacology, pathology, medicine, surgery, obstetrics, gynaecology, forensic medicine, hygiene. The prize is open to all graduates of the University of Oxford who have procured, or are proceeding, to a medical degree in the University. Candidates must not have exceeded twelve years from the date of passing the last examination or the Degree of B.A. and must not, at the date of application, be Fellows on the foundation of Dr. John Radcliffe. Candidates must send in their memoirs to the Secretary of Faculties, at the University Registry, Oxford, on or before January 1st, 1935. The award will be made in March, 1935. No memoir for which any University prize has already been awarded is admitted to competition for the Radcliffe Prize; and the prize will not be awarded more than once to the same candidate.

Board of the Faculty of Medicine

The Board has co-opted Dr. E. W. Ainley Walker, Fellow of University College, and Dr. A. M. Cooke, Jesus College, for the statutory period of two years. The Board has appointed Dr. O. L. V. S. de Wesslow, Corpus Christi College, to be an Elector to the Professorship of Pharmacology, vice Sir Charles Sherrington, who retires under the

Professor of Pathology

The Electors to this Professorship propose shortly to proceed to an election of a Professor in the place of the late Professor Georges Dreyer. Candidates should send in their names, with eight copies of any statement, references, and testimonials that they may think it desirable to submit, so as to reach the Registrar not later than December 22nd. Candidates are requested to state the earliest date on which they could take up their duties. The choice of the Electors will not necessarily be limited to those who apply. The stipend of the Professorship is £1,200 a year, in addition to which there is a special allowance of £200 in respect of duties as Head of the Department. Subject to the provisions of Stat. Tit. IV, Sec. III, cls. 5 and 6 a non-stipendiary professorial Fellowship at Lincoln College is attached to the Professorship. In accordance with the provisions of the University superannuation scheme the Professor will be required to become a member of the Federated Superannuation System for Universities.

During the illness of the Regius Professor of Medicine official correspondence intended for Sir Farquhar Buzzard should be directed to Professor J. A. Gunn, Department of Pharmacology.

UNIVERSITY OF CAMBRIDGE

The Appointments Committee of the Faculty of Biology "B" gives notice that it will shortly proceed to appoint a university demonstrator in pathology. The appointment will be governed by the statutes of the University, and particulars as to stipend and duties may be obtained from Professor Dean, at the Department of Pathology (Tennis Court Road, Cambridge), to whom applications should be sent on or before December 1st.

At a congregation held on November 3rd the following medical degrees were conferred:

M.D.—A. Barnsley, A. Eckford, W. E. Chiesman.
M.B., B.Chir.—E. V. Bevan, H. B. May, J. Metcalf, F. E. Pilkington, R. L. Benison.
M.B.—T. A. Ratcliffe.
B.Chir.—J. H. Conyers.

The Molteno Institute

During the inquiry, as the result of which the General Board proposed regulations for the Molteno Institute of Parasitology, it formed the opinion, both on general grounds and on the particular ground of the temporary association of the Quick Professorship with the Directorship of the Institute, that it would be to the advantage, both of the University and of the Institute, if the scope of the latter was widened. Professor Nuttall has now consulted Mr. Molteno, who cordially approves the proposal to change the title of the Institute to the Molteno Institute of Biology and Parasitology. The Faculty Boards of Biology "A" and "B" have expressed their concurrence, and appropriate recommendations are published in the *University Reporter*.

UNIVERSITY OF LONDON**LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE**

Kenneth Mellanby, B.A., Ph.D., has been appointed to the Wandsworth Scholarship for Research in Tropical Medicine for a period of two years.

The following degrees were awarded by the Senate on October 24th:

Ph.D. in ANATOMY.—Ralph Brooke (Guy's Hospital).
Ph.D. in HELMINTHOLOGY.—Phyllis Annie Clapham (London School of Hygiene and Tropical Medicine).

NATIONAL UNIVERSITY OF IRELAND

A meeting of the Senate was held on October 25th, under the chairmanship of the Chancellor, Mr. Eamon de Valera.

The reports of the examiners on the autumn examinations were considered, and passes, honours, etc., awarded in connexion therewith. The reports of the examiners in connexion with travelling studentships and other prize examinations were also considered, and the following among other awards were made: Dr. Henry Hutchinson Stewart Medical Scholarships: (in Anatomy) J. Burke, University College, Cork; (in Physiology) R. G. Barry, University College, Cork; P. F. Brennan, University College, Dublin; J. Burke, University College, Cork. Dr. and Mrs. W. A. Browne Gold Medal: Paula Mecklenburg, University College, Dublin.

The Senate decided that a special first University examination in Medicine should be held in March, 1935, for students who have completed the lectures therefor; that the Dr. Henry Hutchinson Stewart scholarships in arts, in medicine, and in mental and nervous diseases should be offered for competition in 1935; and that travelling studentships in chemistry and mathematical science should be offered for competition in 1935 as additional travelling studentships.

Obituary

DR. GEORGE ADKINS

With the death of Dr. George Adkins the West Country loses one of the best-known and most respected pioneers of the Public Health Service. Dr. Adkins was trained at the London Hospital, qualified in 1882, and took his D.P.H. at Cambridge University in 1888. He began his medical career in general practice with his father at Yealmonth, Devon, where he was also medical officer of health to Plympton rural district. Later he joined a practice in Paignton, but left there to serve in the South African War, where he contracted typhoid fever. After the war he practised in the Isle of Wight until 1908, when he returned to Devonshire as first county medical officer of health. In Devon he faced the initial difficulties with courage and energy, inspired, as always, by high professional ideals. Gradually a very competent staff to help with tuberculosis and the school medical service was got together, and when in 1929 Dr. Adkins finally laid aside his life's work he was held in universal affection and esteem by all those whose good fortune it was to be associated with him.

Dr. Adkins possessed deeply religious convictions, and was always ready to turn his energy and ability to the assistance of any good work, such as that connected with the Church and with the Boy Scout movement. He was a member of the British Medical Association from June, 1892, until January, 1929, when he resigned. Devon regards his loss as irreparable, but he has left behind him a magnificent example as an inspiration to those who follow.

Dr. ARTHUR DEAKER OWEN died on November 1st at St. Mary's Hospital, Hampton, at the age of 73, after three months' illness. He was the son of Dr. Edward Thomas Owen of Totnes and Plymouth. He was educated at King's School, Bruton, and the London Hospital. After qualifying M.R.C.S., L.R.C.P., and L.S.A. in 1884, and acting as house-surgeon to the Teignmouth Hospital and the Portsmouth Royal Hospital, he accepted an appointment in Government service in the Federated Malay States. Over forty years ago he returned to England and settled in practice at Hampton-on-Thames, only retiring at the beginning of his last illness three months ago. While in practice at Hampton, Dr. Owen held many public appointments. He was honorary surgeon to St. Mary's Hospital, Hampton, medical officer in charge of the Isolation Hospital, Hampton Hill, M.O.H. to the Hampton Urban District, police surgeon, and surgeon to the Metropolitan Water Board. He had been a member of the British Medical Association for forty years.

"S. C. S." writes: It was my very great privilege to be in partnership with Dr. Owen for more than ten years. I think he was the ideal family doctor. He was a sound clinician, and to an inborn skill was added the outcome of a lifetime's careful observation and study. He was kindly to all, always cheerful, and of an unruffled and unflinching courtesy. I do not believe that he ever attended a patient without making a friend. The words "beloved physician" have been spoken of many, but I know of none to whom they can apply more truthfully.

Dr. NORMAN FOX EDWARDS, who died on October 27th (his 64th birthday) in a nursing home at Wolverhampton, was the second son of a Manchester physician. He graduated M.B., Ch.B. from the Victoria University of Manchester in 1894, and after filling various resident appointments in provincial institutions entered upon general practice at Broseley in Shropshire. There he remained for over thirty years, becoming a member of the British Medical Association in 1912 and con-

tinually extending the area of his practice. His whole heart was in his work, and he was a man who thought things out and gave of his best ungrudgingly. He retired from active work in 1930, and went to live near Bridgnorth, close to his beloved Severn. The illness which ended his life was of only one week's duration. He was buried on October 30th in the romantic churchyard of Quatford, overlooking one of the loveliest reaches of the Severn. In 1909 Dr. Fox Edwards married Isabel, daughter of the late Joseph Hartley of Glazebury, who, with a son and two daughters, survives him. In his early manhood he was an athlete and long-distance swimmer, whilst for many years before his death he was an ardent fisherman, and had acquired a wide reputation for his knowledge of the art of fly-fishing. The large number of people who came to his funeral from the Broseley district, and from Bridgnorth, showed how greatly he had endeared himself to his patients, and how sincerely he will be mourned by all who knew him.

The Services

HONORARY SURGEON TO THE KING

Major-General Sir Frank P. Connor, D.S.O., F.R.C.S., I.M.S., Honorary Surgeon to the Viceroy, has been appointed Honorary Surgeon to the King, in succession to Brevet Colonel G. D. Franklin, C.I.E., O.B.E., I.M.S., who has retired.

Major William Leslie Bennett, R.A.M.C. (ret.), died at Swanage on September 8th, aged 57. He was born on August 23rd, 1877, and educated at Glasgow, where he graduated M.B. and Ch.B. in 1898. He also took the F.R.C.S.Ed. in 1906. Entering the R.A.M.C. as lieutenant on June 21st, 1900, he became major on March 21st, 1912, and retired on half pay on March 1st, 1917.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons spent most of this week in committee on the Betting and Lotteries Bill. Discussion arose on a proposal to authorize the establishment of a State lottery. The proposal to prevent the remittance of money to foreign lotteries was discussed.

In the House of Lords the Incitement to Disaffection Bill was considered.

On October 31st Sir HILTON YOUNG presented in the House of Commons a Poor Law Bill "to amend the enactments relating to the relief of the poor in England and Wales so as to secure uniformity throughout Great Britain in the provisions relating to the disregarding of sick pay, maternity benefit, and wounds or disability pensions." The Bill provides that "in granting outdoor relief to any person the council of a county or county borough shall not take into consideration any maternity benefit under the National Health Insurance Acts, 1924 to 1932, except any increase of such benefit by way of additional benefit and any second maternity benefit; any wounds or disability pension received by a person whose resources are taken into account in relieving him, except so far as it exceeds one pound a week, the expression 'wounds or disability pension' meaning any retired pay or pension to which Section 16 of the Finance Act, 1919, applies."

Distribution of Radium

Replying on November 6th to Sir A. Wilson, Sir HILTON YOUNG said that his attention had been drawn to the adverse criticism, in the fifth annual report of the Radium Commission, on the state of affairs at the Bristol centre (University of Bristol and Bristol Royal Infirmary) and the Newcastle centre

(University of Durham and Newcastle Royal Victoria Infirmary). It was the duty of the Radium Commission to distribute the radium at their disposal to the best advantage, and it appeared, from the report of the Commission, that they had transferred some radium from certain centres where it was not being fully used to others. He had no power to instruct radium centres how they should make the best use of the radium supplied, but one of the conditions of the loan to a hospital was that the latter should accept and treat suitable and properly accredited patients from any source.

Road Accident Figures.—Mr. HORE-BELISHA told Mr. Parkinson on October 31st that 5,243 persons were reported as having died as a result of road accidents during the first nine months of 1933. For the first nine months of 1934, as a whole, the number of fatal accidents appeared to have been approximately the same, but comparison for the last two months of the period showed an improvement. Statistics of persons injured in road accidents during 1933 were available only for the year as a whole, but it was estimated that during the first nine months of that year the number was approximately 164,100. For the corresponding period of 1934 the number was approximately 176,200. The rate of increase over last year had been falling steadily during the last two months.

Water Supplies: Present Position.—Answering Mr. D. Grenfell on November 1st Sir HILTON YOUNG said the average rainfall for September was above the normal, but October had been dry, particularly in the Midlands and the South. Returns received from water undertakers showed that the position generally was better than in the summer, and that where shortage existed or was threatened, remedial measures had been taken by providing additional supplies, or by economies in consumption. Water undertakers generally had the situation in hand, provided that, where necessary, consumers continued to co-operate by economies in the use of water. In very few urban areas had there been serious curtailment of supplies. On the same day the Minister told Mr. Parkinson that applications for grants for rural water schemes had been received from 210 rural district councils, for 1,189 parishes, and from twelve urban district councils, for schemes estimated to cost £3,270,000. Grants had been provisionally allocated in respect of schemes for 712 parishes and those of 219 parishes were under consideration.

Sir HILTON YOUNG stated on November 6th that measures were in train for a survey of water resources. He hoped shortly to announce them.

Atophan.—Sir JOHN GILMOUR told Captain Cunningham-Reid on November 1st that he was bringing the evidence of the professor of pharmacology at Birmingham University, and the remarks of the Birmingham coroner at a recent inquest on the effects of the drug atophan, to the notice of the Lord President of the Council and the council of the Pharmaceutical Society, the authorities responsible for additions to the Schedule of Poisons.

Milk During Pregnancy and Lactation.—Sir HILTON YOUNG told Miss Rathbone on November 1st that there were 422 maternity and child welfare authorities in England and Wales. The great majority of them exercised their powers under the Maternity and Child Welfare Act, 1918, to provide milk and food for mothers during the last three months of pregnancy and during lactation, but the actual number was not available. In a circular addressed to local authorities on October 10th on the subject of maternal mortality, he had stressed the importance of using these powers in appropriate cases.

Local Authorities and Maternal Mortality.—In reply to Mr. Palling on November 1st Sir HILTON YOUNG said he was aware that the annual report of the Chief Medical Officer of the Ministry of Health for 1933 showed that the councils of eight counties, seven county boroughs, and five metropolitan boroughs had sent no confidential reports on maternal deaths to his Department. He had no power to require submission of such reports, but every opportunity was taken of urging upon the local authorities the importance of co-operating in the desired inquiries. Even in cases where the reporting medical officer did not feel justified in furnishing any com-

ments on, or interpretation of, the facts disclosed, the reports did not necessarily lack evidence of careful investigation. Medical officers of his Department who examined the reports had the advantage of the advice of two consultant obstetricians, whose services had been retained for the purpose.

Workmen's Compensation and Cardroom Workers.—Replying to Sir John Haslam on November 1st Sir JOHN GILMOUR said he had considered scheduling cardroom workers under the existing Workmen's Compensation Acts, but there would be great difficulties in meeting the position by adding to the schedule of industrial diseases under the Act, having regard to the absence of any special clinical features which would enable the lung condition of the workman to be diagnosed as due to dust. He had written to the Employers' Federation urging it to consider some special scheme, and suggesting that it should arrange for an early meeting of representatives of both sides to explore the problem.

Housing.—Sir HILTON YOUNG told Mr. White on November 1st that he did not think provisions to enable local authorities to control ribbon development could conveniently be included in housing legislation. In reply to Captain Waterhouse, on the same day, the Minister said the policy of the Government was not to confirm any order by a local authority seeking to include in a clearance area, under the Housing Act, 1930, a building fit for habitation, merely by reason of its bad arrangement in relation to its neighbourhood or on account of the narrowness or bad arrangement of the streets.

Exhaust Fumes.—Mr. HORE-BELISHA told Mr. Parkinson on November 1st that the report of a Home Office Departmental Committee, which considered the harmful effects of fumes from motor vehicles on the general health of the public, did not suggest that there was such evidence of injury as would justify legislative action.

Imported Milk.—Sir HILTON YOUNG told Mr. Lambert on November 1st that he did not consider an investigation into the health of the animals producing the milk and into the cleanliness of the manufacture of the milk products imported from foreign countries was needed. Imported milk was subject to special bacteriological conditions which did not apply to home-produced milk, and all milk products to examination at the port of entry to ensure that they were fit for human consumption.

Control of Poisons in Agriculture.—Sir JOHN GILMOUR, on November 5th, told Sir John Wardlaw-Milne that the control to be extended to retail distribution of poisons used in agriculture and horticulture was among the matters under examination by the Poisons Board. The Board had invited the observations of associations of manufacturers, traders, and others upon a draft of the proposals to be later submitted, and he would consider their recommendations when all the observations had been received.

Outbreaks of Foot-and-mouth Disease.—Dr. ELLIOT, replying on November 5th to Mr. W. Nicholson, said that during the past three months seven outbreaks of foot-and-mouth disease had occurred which could not be attributed to previous cases in this country. In none of these outbreaks was the source of infection definitely established, and in no case was there reason to believe that animals imported into this country were the first to be affected.

London Refuse Disposal.—Mr. SHAKESPEARE, on November 5th, informed Sir C. Rawson that the Minister of Health was aware of the interim report of the Cleansing Subcommittee of the Metropolitan Boroughs Standing Joint Committee on the Disposal of Refuse. The Minister was advised that where controlled tipping could be and was properly carried out it was a satisfactory method of disposal. The method is most advantageous, for any particular place must depend on local circumstances.

Maternal Mortality in Liverpool.—Sir HILTON YOUNG, on November 6th, told Sir A. Wilson that there was no evidence from statistics that any increase in the maternal mortality rate in Liverpool was caused by malnutrition of mothers. The Liverpool rate was still well below that for the whole country.

Total Blindness from War Service.—On November 6th Major TRYON told Lieut.-Colonel Moore that during the last five years eighty-six cases had been admitted to pension in respect of eye disabilities resulting from war service. Of these, two were cases of total blindness.

The "Silent Zone" and Road Safety.—Mr. HORE-BELISHA informed Mr. Robinson that the institution of the "silent zone" had met with overwhelming approval. It was not primarily instituted to promote safety but to increase the opportunities for rest and recuperation of workers and the sick. This purpose had been achieved without any increase in the number of accidents being attributed to the new regulation. He was not at the moment prepared to make a general prohibition of the use of motor horns and other noisy indications of approach. Mr. Hore-Belisha informed Dr. Salter, on November 5th, that from July 9th, 1934, the date on which uncontrolled pedestrian crossing-places were first laid down in the metropolitan police district, to October 31st inclusive, four persons were killed and 194 injured on these uncontrolled crossings.

Notes in Brief

An explanatory circular to local authorities on the Shops Act, 1934, will shortly be issued.

Persons in receipt of poor relief in England and Wales—including dependants but excluding rate-aided patients in mental hospitals, persons in receipt of domiciliary medical relief only, and casuals—on October 13th, 1934, numbered 1,310,668. Of these, 134,854 were chargeable in Wales with Monmouth.

Medical News

The fifty-seventh anniversary dinner of the Cambridge Graduates' Club of St. Bartholomew's Hospital will take place on Wednesday, November 21st, at 7.30 p.m., at the May Fair Hotel, with Professor Francis R. Fraser in the chair. The honorary secretaries are Dr. H. N. Burroughes and Mr. Reginald Vick.

The annual dinner of the Prince of Wales's Hospital Club will be held at the Trocadero Restaurant on Thursday, November 22nd, at 8 p.m., when Dr. Lewis R. Yealland will occupy the chair. Price of dinner, exclusive of wine, 12s. 6d., to be paid in advance. Members are asked to notify Dr. Bertram H. Jones (honorary secretary), 47, Queen Anne Street, W.1, of intention to be present, stating number of guests. (Lady guests may be invited.)

A meeting of the Tuberculosis Association will be held at 26, Portland Place, W., on Friday, November 23rd, at 5.15 p.m., when Dr. L. S. T. Burrell will deliver his presidential address, on "Tuberculosis Reinfection in Adults." At 8.15 p.m. Dr. G. T. Hebert will read a paper on "The Termination of Artificial Pneumothorax Treatment."

The Royal Sanitary Institute will hold a joint meeting with the Yorkshire branch of the Society of Medical Officers of Health at Huddersfield Town Hall on Friday, November 16th, at 6 p.m., when there will be discussions on "The Huddersfield Scheme for Maternity and Child Welfare Work," to be opened by Dr. John M. Gibson, and on "Recent Housing Developments in Huddersfield," to be opened by Mr. G. Crossley.

A course of twelve illustrated lectures on the geology and scenery of the Hebrides will be given by R. M. Craig, D.Sc., in the lecture theatre of the Imperial College of Science, Exhibition Road, South Kensington, on Mondays, Wednesdays, and Fridays, at 5.30 p.m., from November 26th to December 21st, inclusive. Admission free.

The Central London Throat, Nose, and Ear Hospital (Gray's Inn Road, W.C.) has arranged a week-end course in laryngology, rhinology, and otology, specially suitable for general practitioners, on Saturday and Sunday, December 1st and 2nd, at 10.30 a.m. The fee for the course is £1 1s. 6d., and the names of those wishing to

attend should be sent to the secretary-superintendent as soon as possible.

Dr. Leonhard Seif of Munich will give a course of three lectures on November 20th, 23rd, and 26th, at 8.30 p.m., on "The Principles and Practice of Individual Psychology." The course, which has been arranged by the Child Guidance Council for members of clinic staffs and others, will take place at the Institute of Medical Psychology, Malet Place, W.C. Admission free.

The Royal Photographic Society is holding an exhibition of cinematography at 35, Russell Square, W.C. It is designed to show recent advances with special reference to the progress achieved in design of apparatus and the extension of the sound film to substandard sizes—developments which bring "talkies" into the class room, the social centre, and the home, and open up a new field in educational, cultural, and entertainment possibilities. The exhibition will be open, free, to the public until November 30th, on Mondays, Wednesdays, and Thursdays from 10 a.m. to 9 p.m., and on Tuesdays, Fridays, and Saturdays from 10 a.m. to 6 p.m.

A general course of post-graduate instruction, arranged by the University of Durham College of Medicine, opened at the Royal Victoria Infirmary, Newcastle-upon-Tyne, on October 11th, and will be continued on Thursdays at 1.30 p.m. to December 13th, with the exception of November 15th, which date has been left vacant so that members may attend the scientific demonstrations arranged by the North of England Branch of the British Medical Association. A special course in midwifery and gynaecology is being held on Wednesdays at 3 p.m. Classes for clinical instruction in medicine and surgery, or lecture-demonstrations, will be continued every Sunday at 10.30 a.m. to December 16th. All medical practitioners are invited to attend these classes, for which there is no fee, and particulars will be given week by week in the diary column of our Supplement.

The Fellowship of Medicine (1, Wimpole Street, W.1) announces that lecture-demonstrations will be given at 11, Chandos Street, W., on November 13th and 20th, at 2.30 p.m. At the same place Dr. Christie will lecture on diet of the obese and thin, on November 14th at 8.30 p.m. Forthcoming courses include gynaecology at the Samaritan Hospital, November 17th and 18th; proctology at St. Mark's Hospital, all day, November 19th to 24th; rheumatism at the British Red Cross Clinic, Peto Place, N.W., on Tuesdays and Thursdays at 8.30 p.m., November 20th to December 6th; infants' diseases at the Infants Hospital, every afternoon, November 26th to December 6th; dermatology at the Blackfriars Skin Hospital, every afternoon November 26th to December 6th. A special M.R.C.P. course in chest diseases will take place at the Brompton Hospital on Wednesdays and Fridays, for four weeks, from December 12th to January 11th (excluding the Christmas week). Courses of instruction are open only to members and associates of the Fellowship.

The ninth Pan-American Sanitary Congress will be held at Buenos Aires from November 12th to 22nd, when papers will be read on hospital organization, venereal disease, small-pox, malaria, undulant fever, leprosy, yellow fever, milk, infantile mortality, tuberculosis, school hygiene, narcotics and alcoholism.

The eleventh Voyage Médical International on the Riviera, organized by the Société Médicale du Littoral Méditerranéen, will take place from December 26th to January 3rd, under the presidency of the dean of the Faculty of Medicine of Paris. The principal places to be visited are Nice, Cannes, Menton, Monte Carlo, Beaulieu, Grasse, and Vence. Further information may be obtained from the Federation of the Health Resorts of France, Tavistock House (North), Tavistock Square, London, W.C.1.

The issue of *Paris Médical* for October 20th is devoted to diseases of the kidneys and urology.

Mrs. Stanley Baldwin opened the new private wards at the Hendon Cottage Hospital, N.W., on the afternoon of Wednesday, October 31st.

A short ceremony in connexion with the transfer of Heatherwood Hospital, Ascot, to the London County Council by the United Services Fund took place at the hospital on November 2nd, when the title-deeds of the hospital were formally handed over by Major-General Lord Lock (chairman of the council of management of the United Services Fund). Mr. Somerville Hastings, F.R.C.S. (chairman of the Hospitals and Medical Services Committee of the L.C.C.), accepted the gift on behalf of the Council.

Dame Edith Powell, widow of Sir Richard Douglas Powell, first baronet, left £48,562. Her bequests included £1,000 to the Royal College of Physicians of London as a memorial of her husband, who was President from 1905 to 1910.

The King has granted permission to Dr. C. E. G. Beveridge to wear the insignia of the fourth class of the Order of the Nile, conferred upon him by the King of Egypt in recognition of valuable services rendered.

The chairs of medical pathology, medico-surgical anatomy, and operative medicine, and nine assistant professorships in the Paris Faculty of Medicine have recently been abolished. On the other hand, chairs for medical anatomy, dietetics and physiotherapy, hydrology and climatology, have recently been founded at Geneva University.

The American Congress of Physiotherapy has awarded its highest distinction, the Gold Cross, to Dr. Henri Bordier, professor of medicine at Lyons, for his studies in the physiology of high-frequency currents, to Dr. Oscar Bernard of Saint-Noritz, and to Dr. Franz Nagelschmidt of Berlin.

Dr. Gudmundur Hannesson, professor of anatomy and hygiene at Reykjavik, has been awarded the gold medal of honour by the University of Hamburg, and Dr. T. von Györy, professor of the history of medicine at Budapest, the Karl Sudhoff medal.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS., if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is LUSTON 2111 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Medisecra Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Treatment of Chronic Nasal Discharge

Dr. P. LIONEL GOITEIN (London, W.1) writes: In searching for a "hopeful" formula for this distressing symptom, is it within the bounds of possibility that your correspondent "M. S." (October 27th, p. 786) has been working too exclusively from the physical angle, and has overlooked what has proved (at least in my hands) a very

helpful approach—namely, the psychological? "M. S." does not state whether the sinus and antra operations were necessitated by, or resulted in, this symptom. If non-purulent, I should like to emphasize from experience that psychotherapy can be trusted to dispel the symptom in question often quite dramatically. The nose is frequently utilized as a safety-valve for solving emotional conflicts, and other tensions, with copious rhinorrhoea. Hence, vicarious menstruation and the like anomalies. Certain hysterics and obsessionals are only too happy to side-track the issues in physical treatment. I recently had a patient with diuresis and enuresis, complicated by the nasal symptom referred to, who had run the gamut of sensitization, cauterization, catheterization, etc., to both organs, and who was relieved of bed-wetting in the early weeks of treatment. Similarly, one usually finds the adenoidal (and sinusoidal) conditions clear up—as they did in this case—soon after, and this without recourse to aught but modern psychological technique. While this is not vaunted as the treatment *par excellence* of all the mucorrhoeas, its use (in the absence of gross traumata or infective agents) is undoubtedly well justified:

Treatment of Trichophyton Infection

"AGRESTIS" (East Lothian) writes: There have been lately in your columns many communications on the treatment of this troublesome condition, but it has struck me that none of the writers has stated that his own particular method has cured himself. If the criterion of treatment is cure, I may feel some slight justification for writing now. I have for many years suffered intermittently from the condition, and after trying a variety of applications which produced not the slightest benefit, I fell back upon a simple, and what appeared to me to be a logical, form of treatment. Moisture is necessary for the growth of all moulds, and if a part is kept dry the soil is rendered less suitable, or at any rate conditions for growth become less favourable. Relative dryness can be ensured by the insertion of small strips of boric lint in the interdigital spaces. The strips should be in size about one inch by one-half inch, and they should be pressed well into the affected spaces. In my own case a fairly extensive and long-standing infection was comparatively quickly healed by this simple method, and recurrences in the favourite site of the fourth interdigital space are very quickly "scotched" by it. I can certainly recommend its trial, in association with the implied methods of cleanliness. The strips should be renewed night and morning.

Treatment of Ménière's Disease

Dr. R. H. BOTHAM (Manchester) writes: In answer to "Inquirer" (*Journal*, November 3rd, p. 843), I can recommend him to try the method of treatment of Ménière's disease set forth by Dr. W. S. Thacker Neville in an address to the Darlington Division of the R.M.A. in March, 1931. The address was published subsequently in the *Journal* of July 11th, 1931 (p. 54). The method is simple, and consists in the elimination of all salt from the diet, and the reduction of the fluid intake to the lowest endurable point. The object aimed at is the reduction of fluid pressure in the vestibule and semicircular canals. In my own case the attacks ceased at once after beginning treatment.

Income Tax

Interest on Borrowed Capital

"R. S." pays £300 a year interest, and last year deducted £75 therefrom, being income tax at 5s. in the £. What is the position if the tax payable in respect of his profits—and any other income he may have, for example from owning his own premises—comes to less than £75?

His minimum liability for the year is £75; when he has paid that and no more he has merely handed over the tax which he deducted—collected so to speak—on behalf of the Revenue, and has ultimately borne no tax himself.

Debts Outstanding on Retirement

"R. F." has retired, and the inspector of taxes wants him to pay tax on debts owing to him.

The inspector is probably right, in the circumstances, to insist on the last year's account being made up on a basis that shall adjust the cash receipts to an "earnings basis." Consequently any increase during that year, of the value of the debts on the books, can be brought into the calculation. But this does not mean that the amount (or value) of the debts at the end of the period can be brought in as receipts without deducting the corresponding total at

the commencement, and "R. F.'s" letter suggests that this is what the inspector is seeking to do. The inspector is correct in saying that unless the gross amounts of the debts are brought in they must be separately valued. An estimated percentage is not sufficient compliance with the statute.

General Practice and Appointment

"D. C." has an appointment which he regards as an essential part of his practice. The inspector refuses to include the emoluments in the general Schedule D assessment, claiming to assess it separately under Schedule E.

"* It is beyond doubt that the emoluments of a specific employment are assessable under Schedule E, but there is a general and officially approved practice of pooling such receipts in the Schedule D assessment. We are not informed of any special circumstances in this case. It might be advisable to ask the inspector for the reason why he is not following the general practice, and we shall be pleased to advise further if necessary.

LETTERS, NOTES, ETC.

Treatment of Ozaena

Dr. ELIZABETH C. MUDIE writes: I venture to give details of the treatment advocated by me for the distressing condition known as ozaena. Locally the patient applies a small pledget of cotton-wool to each nostril. This is soaked first in a strong solution of lactose at blood temperature. In addition, the nose and pharynx should be thoroughly douched, at first every two or three hours, afterwards thrice daily, in the solution, two drachms of lactose to four ounces of water being sufficiently strong. The rationale of this treatment is obvious. Saprophytes which are responsible for the condition split the lactose and release lactic acid, nature's premier disinfectant. The treatment is equally good for all cases of nose and throat catarrh. Constitutional treatment lies in a thorough revision of diet, with moderation of meat intake. Cheese, eggs, milk, whole-wheat bread, rye bread, and coarse oatmeal cakes, vegetables of all kinds, conservatively cooked, green salads in abundance, tomatoes, raw fruit, and plenty of tap-water will do more to alleviate and cure such a condition than any other measures. Sugar, cakes, pastries, and sweets must be absolutely cut out of the diet, and tea sparingly taken—never with food. Buttermilk may be drunk with advantage at meals, but nothing but water between meals. Aim at two or three quarts daily. Artificial or real sunlight on the naked body will hasten the cure, and abundance of fresh air must be available during sleep. One of the finest intestinal cleansers I know is garlic. There is a popular prejudice against this pungent vegetable, but I am ready to believe that those who live with a victim of ozaena would rather endure the smell of garlic as the lesser of two evils. One clove or division of garlic thrice daily for a week or ten days will work wonders.

Motoring and the Expectant Mother

Dr. P. Labignette, writing in the *Rev. Med. Latino-Americana* for June, 1934, discusses the risks undergone by the indiscriminate use of the motor car during pregnancy, and believes that it has not yet attained to such a degree of mechanical perfection as to exempt its employment from interference with that condition, even in normal cases. During all abnormal pregnancies, early or advanced, or when past history gives indication of a tendency to abortion, all motor journeys should be forbidden. The car should always be well sprung. It is, states this author, the doctor's duty to inquire into the condition of springs, tyres, seats, and shock absorbers, and if in any doubt he should make a trial trip himself. The patient should not drive; and during the first twelve weeks and the final, or even the penultimate, month, she should be doubly cautious, especially if a primipara. Long journeys, especially if extending over several consecutive days, cannot be advised: if they are imperative, a gentle opiate douche or suppository is a valuable precautionary measure. To minimize pelvic congestion the expectant mother should leave the car and walk a short distance every two hours. The smoothest routes should be chosen, and the driver should not travel at a rate of more than about thirty miles an hour, and should avoid all bumping and jolting. In conclusion, Labignette states that when consulted as to the proposed journey the obstetrician must be cautious.

If he forbids it and his advice is ignored he will be laughed at should no harm ensue. If he assents, should the patient abort, his reputation will suffer.

The Herbalist at Home

The *British Medical Journal* of May 27th, 1911, was devoted to quackery in all its aspects, and it contained a section on Herbalists and Medical Practice which began thus: "While it is no doubt well known to most of our readers that among the many varieties of unqualified persons who profess to treat disease there are some who call themselves herbalists, medical botanists, or by some similar name, it is perhaps less generally known that these herbalists have a definite organization and a monthly organ, and that they aspire to the possession of a right to practise equal to that of the qualified and registered medical practitioner." Some particulars in regard to this matter culled from the publications of herbalists were therefore included, and curious reading they make. We do not know if the *Herb Doctor* survives to-day as a periodical, but herbalists still ply their trade in "simple vegetable remedies, free from all injurious chemicals." Dr.

Ladies and Gentlemen, After a period of 39 years (thirty years) of hard study and wide experience, a Port Talbot expert claims to cure most diseases that form on human beings. Don't take to be persuaded by anyone, but come and see for yourself. We do not pretend to make miracles but out to assist nature, and the first complaint now to mention, and a very drastic one, is—

CANCER

It can be cured in 5 weeks (five weeks), also Tumours in less time. Consumption will absorb more time than above complaints, but from three to five months, without fail, this also can be cured of the worst stage, that is if you follow our instructions.

Rheumatism, Appendicitis, in four hours, or inflammation in any part of the body. Fits, Gall-stones, Dropsy and Asthma attacks can be released in ten minutes, and prevention can be had when you ask for it.

Expert: Mansel St., PORT TALBOT

H. R. Frederick sends us from Glamorgan a choice specimen of the kind of printed circular that still finds its way through letter-boxes in South Wales and other parts of our credulous island. "This struck me," Dr. Frederick writes, "as a masterpiece, reminding me much of the old quacks' circulars of the sixteenth and later centuries." A reproduction of the ingenious leaflet is printed herewith, but we have omitted the self-styled expert's name.

The Grenfell Calendar

Among the first of the 1935 calendars to arrive is the Grenfell Calendar, which is again being sold in aid of the work of Sir Wilfred Grenfell in Newfoundland. In size and design it is exactly similar to last year's—namely, a page for each seven days with space for noting morning, afternoon, and evening engagements; there is also a further selection of photographs of Labrador and Northern Newfoundland. Its attractive design and reasonable price (3s. 6d.) make this calendar a suitable gift for this season of the year. It may be obtained from the Grenfell Association, 66, Victoria Street, S.W.1.

Correction

In the leader on "La Granulie Froide" (*Journal*, November 3rd, p. 815) the second reference should be to the *Bull. et Mém. Soc. Méd. des Hôp. de Paris* of June 25th, 1934, p. 886, and not to *Bull. et Mém. Soc. de Méd. de Paris* of June 15th.

The Marmite Food Extract Company Limited (Walsingham House, Seething Lane, E.C.3) has published a new booklet, based on many references to the therapeutic value of marmite which have appeared recently in medical literature.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 50 and 51. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 249.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, NOVEMBER 17th, 1934

SOME ASPECTS OF PAIN*

BY

MACDONALD CRITCHLEY, M.D., F.R.C.P.

JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL; ASSISTANT PHYSICIAN,
NATIONAL HOSPITAL, QUEEN SQUARE

The various biochemical and metabolic changes that have at times been regarded as the effects of pain are of very limited value. Inconstant, unreliable, and non-specific, they tell us little as to the nature, intensity, and site of the pain, or even, indeed, as to its very existence. Many of these data have been determined by animal experimentation, and are entirely inapplicable to the study of pain as a process of human mentation. Some of the changes occur whether anaesthesia is employed or not, and cannot therefore be directly linked with the conscious appreciation of pain. The all-important factor of the concomitant feeling-tone is entirely ignored, and we do not know what part is played by the coexisting fear, anger, depression, and exasperation. When the physiologist discusses the "bodily changes in pain, hunger, fear, and rage" we are persuaded to regard them as identical. Pavlov's work with pain analysers illustrates the extreme diversity of the possible results.

The Psycho'logical Concomitants

The psychological concomitants of pain are manifold. An acute pain, when severe, usually dominates the victim's sensorium, often to the exclusion of other internal and external impressions. In other words, there arises a state of preoccupation or inattention to environmental stimuli. This is one of the most common feeling-tones associated with pain. There results an inability to concentrate upon physical or mental activities. Irritability is another very frequent occurrence during states of painful experience.

The major affects of rage, fear, anxiety, or despair may also accompany the feeling of pain. Their presence depends upon the nature of the pain and the circumstances under which the suffering occurs. Thus, the pains of punishment, conflict, illness, and surgical manipulations differ radically in their attendant circumstances, and they will obviously produce very different emotional states. A sudden violent blow will evoke sentiments of anger, or perhaps of fear, as well as a feeling of pain: a victim suffering the agonies of colic or of angina is assailed not only with pain, but with feelings of anxiety, uncertainty as to the outcome and duration, and perhaps despair. The victim in the dentist's chair may undergo his sufferings with alarm, but no anxiety assails him as to the possible deadly significance of his pain or its duration.

It is a commonplace that under the stress of an agonizing experience the sense of time may be disordered. To the sufferer, time passes at a pace much slower than the common estimate: "each minute seemed an hour" is often heard in descriptions of acutely painful experiences. This point is well emphasized in electrical accidents;

owing to the tonic contracture of the flexor muscles, the hand which makes contact with a live wire may grip still tighter and the victim is unable to release himself, although suffering intense agony. This so-called "elongation of the sense of time" is well illustrated in the following personal accounts:

An engineer who became suspended from a live wire conveying a current of 230 volts writes: "I cannot say how long I was suspended: naturally it seemed ages, but my last feelings before losing consciousness were the most agonizing pains I ever wish to feel." Another, who accidentally seized a telephone wire which was grounded, reported: "The duration of the shock could not have been more than a couple of seconds. A man riding by on a bicycle going at a good speed had only time to pass about thirty yards beyond me when the operator got through talking and opened the switch; yet I could see every spoke in the bicycle and it barely seemed to me to be turning. I could feel every reversal of the current, and these reversals occur at the rate of sixty complete cycles per second. It is this intense activity of the brain to electrical impressions that makes an instant of electric shock seem hours to the sufferer."

It is interesting to recall that depression is rare as a concomitant of severe pain. Older writers often mention that physical and moral pain cannot coexist in any intensity. Ribot puts it: "It seems as though the organism had but a limited capacity for either pleasure or pain, and that neither feeling can exist at the same time in its double (physical and moral) form."

With protracted states of severe pain, marked psychological adjustments are to be anticipated. Whether these will fall into any particular pattern is perhaps questionable, and as much will depend upon the previous personality as upon the circumstances of the present suffering. When disability or disfigurement accompanies the distress, the workings of an organ inferiority may at times be traced. To the layman, chronic pain has long been associated with a subtle process of refining or cleansing whereby the individual is exalted.

Sleep may follow intense suffering, and may even amount to pathological drowsiness. This has been noted in tortured criminals, and lesser examples might be quoted in the drowsiness associated with the severe headache of migraine and cerebral tumours. In the sleep which succeeds or accompanies the exhaustion of torture, dreams of a peculiarly vivid or complex character are often experienced. Jack London has described in *The Jacket (The Star Rover)* the particularly coherent and continuous visions of Durrell Standing while undergoing a series of ordeals by strait-jacket.

He would dream that he was addressing learned societies on abstruse problems, often waking to the sound of his voice ringing in his ears and with imaginary pages of manuscript floating before his eyes; that he was journeying on horseback

* Read in opening a discussion in the Section of Neurology at the Annual Meeting of the British Medical Association, Bourne-mouth, 1934.

through the meadows of some vast farm; day by day the dream story would develop coherently and consecutively, and unroll itself before him. Shrubs and plants would grow from small beginnings into tall vegetation, which would later be felled by the labourers' axes, collected, dried, and burnt in great heaps.

Secondary Sensations

In a few individuals a curious phenomenon may arise during the course of a painful experience. Accompanying the pain feeling—and even at times replacing it—there may be a stimulation of one of the special senses. This is spoken of as a secondary sensation, or "synaesthesia." Secondary sensations associated with a pain stimulus (synalgesiae) are of course merely one of numerous other synaesthetic phenomena which may accompany other experiences. When we read in literature descriptions of painful experiences we not infrequently find the writer using the language of some special sense in order to describe the quality or intensity. Most commonly we find the pain described in terms of colour. This technique may be employed either in the form of a metaphor or of a simile. Thus we find Homer referring to "black pains." Three examples may be quoted in illustration.

In *The Dream Ship* we read: "Bran decided all his likes and dislikes by colour and smell. His favourite colours were yellow, red, green, and wet-black. The last was very similar to ordinary black, which was the colour of toothache. Little rheumatic pains . . . were grey. The worst pain you could get was a purplish-red one."

Again, in Leonhard Frank's *Brother and Sister* we read, apropos of a maternity ward: "There was nothing in the white-painted room but a white-covered ottoman, a white table of instruments, and a white washstand. Lydia was white too, and the doctors and sisters were white. Only the pains had violent colours, all colours."

In describing the pains of a gastric carcinoma J. C. Powys writes in *The Glastonbury Romance*: "The pain took various shapes in Tittie Petheron's consciousness, according to its intensity. What it resembled now was a round black iron ball of a rusty blood colour, covered with spikes."

When we encounter in literature or poetry such metaphorical intermingling of different sensations we perhaps attribute it to the technique of the writer, who deliberately invokes symbols and startling contrasts, metaphors, and discords in order to emphasize and impress. Undoubtedly this view would be not altogether incorrect, but we are also at times witnessing a less conscious expression of the artist's synaesthetic imagery. Many persons habitually experience secondary along with primary sensations, and examples may find their way into literature, and even into popular diction.

In their minute analysis of *die sekundäre Empfindungen* Bleuler and Lehmann write: "Pains are never felt or recollected without their appropriate colours. They are coloured variously, according to their intensity. Violent pains are accompanied by an idea of white; still more intense and localized pains go from yellow to red and to dark brown; dull headaches give a tint which is almost black; darting pains, an idea of white dots, a pinch, a yellow tint, which is clearer the keener the pain is; indigestion, a more or less clear grey; colic, a clear yellowish tint, which may pass over the red or brown."

At the National Hospital for Nervous Diseases a blind patient who had a keen synaesthetic imagery used to describe all pains as red.

Latent synaesthetic faculties may sometimes be enhanced artificially, as, for example, by intoxication with certain hallucinatory drugs. Mescal is one of the most potent pharmacological measures of this type, and Mayer-Gross and Stein record that on stimulating the cold spots of a patient intoxicated with mescal the sensation was described as "cold, lightning-like, unpleasant, light, and blue." But when the stimulus failed to hit off a cold

spot the sensation was described as "soft, diffuse, dark, and blunt." By the same subject hunger was associated with green and pain with bright red. Under conditions of partial narcosis, or when pain appreciation is temporarily blunted or abolished, another sense image may replace the sensation of pain.

Thus, a patient under a light nitrous oxide anaesthesia during a paracentesis tympani saw two revolving circles of light, which, at the moment when the instrument was introduced into the ear, immediately came into contact with a noise like two circular saws. They remained in contact while the instrument was in position, and separated when it was withdrawn. This experience recurred each time the operation was repeated.

An epileptic, describing his attack, writes: "Not unconscious . . . but under no circumstances can I talk or move any limb with complete control. If I fall and hurt myself, even severely, I do not actually feel the pain, but rather hear it."

It is well known, of course, that this synalgesic phenomenon may be reversed. Thus stimulation of a sense channel may evoke a feeling of pain as a secondary sensation, even when the stimulus is not intense. Kipling, in *They*, writes of an old lady whom certain colours "hurt." Féré described itching of the skin on hearing shrill notes, while Bleuler had a carious tooth which would ache when he heard music. Pain on hearing high notes or on intense light stimuli was described by Helmholtz, and has recently been the subject of exact study by Helmsmoortel.

Susceptibility to Pain

Since pain is mainly a personal sensory experience, its study is beset with the difficulties attendant upon all subjective phenomena. When an individual says he feels pain we are almost entirely dependent upon his descriptions if we wish to learn about its site, nature, and intensity; indeed, when we accept its actual existence we rely upon his word alone. Individuals vary considerably in their powers of description, so that knowledge of another's pain is limited by the victim's intellectual and educational status, as well as by his degree of critical introspection and command of language. Could we investigate twenty persons inflicted with an identical pain stimulus—whether it be the extraction of a particular tooth, a hypodermic injection, or a blow—we would certainly find that the twenty descriptions varied considerably, if not the twenty subjective experiences. Some persons, for example, habitually employ superlatives in speech, and will speak of the pain as "agonizing," "terrible," or "excruciating." The appropriate affect is not necessarily present, however.

But despite all verbal shortcomings and exaggerations there exists an obvious difference in the pain reactions of individuals to what is, as near as possible, an identical stimulus. Common experience teaches that the burly, lymphatic artisan feels pain less than the fragile artist or thinker. As Mrs. Browning put it, "the mark of rank in nature is capacity for pain." Precise data in this matter are scant, however, although Macdonald some years ago made a careful psychometric study of pain sensitivity. His findings confirmed the general impressions by demonstrating a greater sensitiveness in the young than in the old, and in women than in men. Social factors were significant, for the cultured, educated, delicately nurtured, and well-to-do suffered more from pain stimuli than the uneducated, harder, poorer classes. Racial factors are of considerable importance, for the white and "civilized" peoples are notoriously more sensitive than coloured and primitive races.

A marked degree of indifference to pain has been associated by Lombroso with habitual criminals—particularly those who are addicted to crimes of great violence and

brutality. Schilder has noted this insensitivity to pain in at least two criminals, one of whom was the infamous Baker. This man had been arrested for the murder of a watchman by stuffing cyanide down his throat. Psychological investigation quickly revealed extreme hatred and marked sadistic tendencies, harking back to early childhood experiences. Baker boasted that he had killed at least ten other persons.

It is noticeable that the degree of pain sensitivity does not correspond exactly with susceptibility to surgical shock. Post-operative experiences teach how well women and young children sustain severe surgical ordeals, although actually very susceptible to pain.

Insensitivity to Pain

Very occasionally one encounters persons who seem to possess such a high threshold for nociceptive stimuli that pain rarely, if ever, enters their experience.

For example, I was once asked to see a pale-faced, weedy young man, because his doctor had noticed him to be relatively insensitive to pinpricks and other painful stimuli. This I confirmed. He did not flinch when I drove a pin hard into him; he stated he could feel the prick, but said that "it was nothing very much." Inquiry revealed that this hypalgesia had always existed; minor surgical measures, such as the lancing of a whitlow, had been carried out without discomfort. On several occasions teeth had been extracted without anaesthetic and with no suffering whatever. Once, during an argument, a neighbour broke an umbrella over his head, but failed to provoke any pain. A noticeable feature in this case was the discrepancy between his insignificant physique and his apparent fortitude.

A similar case has been described by Weir Mitchell. A legal friend of his, who died at the age of 56, had never felt pain keenly at any time in his life. Having had his finger crushed during a dispute over politics, he bit it off. He had an ulcer on the toe for three years, yet suffered no pain. A severe abscess once developed on the hand, and, spreading to the forearm, endangered his life. No pain was felt, however, even when the arm was lanced. Operation for bilateral cataract was performed without the use of a local anaesthetic. Only on his deathbed did he complain of a little discomfort.

More recently Dearborn has published an account of Edward H. Gibson, well known in American vaudeville as "the human pincushion." This man had never experienced pain other than an occasional headache. Numerous accidents had befallen him during the fifty-four years of his life: he had been struck in the face with a pickaxe, his head had been laid open with a hatchet, a revolver bullet had passed right through his index finger, his fibula had been fractured, his nose broken, his hand burnt on a hot gas stove until the smell of charred flesh became noticeable. But in all these accidents scarcely any pain had been experienced, although he had sustained a certain degree of shock in some. An attack of acute otitis media troubled him so little that he did not stay away from school. A double pneumonia and a typhoid ran their course without pain. In his music-hall act he would appear twice daily in appropriate undress and invite members of the audience to thrust pins into him anywhere except the abdomen and the groin. Sometimes at one performance as many as sixty pins would be driven in up to their head. A challenge of 5,000 dollars was offered to any physician who could detect any sign of pain. He once staged a crucifixion act: four gold-plated spikes with needle points were prepared, and a wooden cross was erected. A man then hammered one of the nails through the palm of his hand, and would have continued with the other extremities had not the performance been broken up at this point by the collapse of certain of the audience. There was no evidence in this man's case of obvious nervous or mental disease, and hysteria could be excluded.

Schilder, in discussing this particular case, referred to a similar patient in whom there was a familial incidence of this peculiarity. In Schilder's patient there was no pupillary reaction and no alteration in pulse rate and blood pressure on painful stimuli. Furthermore, there was an extreme degree of sado-masochism.

Varying Pain

Just as persons differ in their susceptibility to pain, so an individual may vary in his sensitivity under special circumstances. Common experience reminds us that under the stress of strong emotion—excitement, anger, pleasure—the threshold for pain becomes temporarily raised. The footballer may be unconscious of the injury which raises a bruise; the soldier may be unaware he is hit until he sees blood flowing from his wound. More prolonged insensitivity may occur in states of exaltation or religious ecstasy, during hysterical states of dissociation, and in mediumistic trances. In other circumstances pain sensitivity may be temporarily lowered. Thus deep introspection, self-analysis, and close attention will augment the effects of stimuli. In certain neuroses and psychoneuroses this process is constantly operating. Some believe that in hypochondria there is a persistent lowering of the threshold, so that quite trivial stimuli are interpreted as pain—possibly even those activities which ordinarily do not reach consciousness, such as the beating of the heart and the movements of the viscera. The threshold for pain may be temporarily reduced by such factors as cold, hunger, and fatigue. Cachectic and debilitated subjects are usually more sensitive to painful impressions. In such mental states as mild depression, particularly when accompanied by agitation, pain susceptibility is increased. With deeper and anergic types of depression, however, the patient may be indifferent to nociceptive stimuli.

The grossest examples of insensitivity are found in certain cases of insanity or mental defect. Idiots and imbeciles often injure themselves by beating their heads against a wall, gnawing their wrists, or pummelling themselves. Cases are quoted of psychotics who plunge their arms into boiling water, or into a fire until the charred flesh drops off, or who chew broken glass.

Goodhart described a post-encephalitic girl who, with her nails, tore out both eyes, with optic nerves attached. Objective tests revealed that ordinarily she appreciated pain stimuli quite normally.

Another case—probably also one of post-encephalitis—has been described by Conn. His patient, a girl of 21, was admitted on account of severe pains in the head and hands. Whilst in hospital she violently fractured all her phalanges, dislocated her thumbs, and tore off her ear. She affirmed that this caused her no discomfort, and, in fact, relieved her pains. She seemed proud of her action and cheerfully displayed her bleeding and mutilated hands to her horrified mother. When asked what was in her mind at the time she injured herself she replied: "I had to see blood, I wanted to see blood come out, I wanted to keep the blood from reaching my head so I wouldn't go out of my mind, as I hadn't menstruated."

The explanation of these insane acts of automutilation is problematical, and may indeed vary with different cases. In some patients the pain experience may be perhaps incorrectly interpreted. Thus, a patient described by Galton once burnt himself accidentally; thereafter he repeated the performance deliberately on several occasions. Perhaps in the majority of cases the self-infliction of pain represents an effort to appease a sense of guilt or to atone for a misdeed, real or imaginary. Thus in Conn's case, quoted above, there was probably a strong feeling of self-reproach on account of masturbatory practices, and the author instances the Biblical injunction, "If thy right hand offend thee, cut it off . . . and if thine eye offend thee, pluck it out."

In a recent novel, J. C. Powys narrates how an obsessional psychoneurotic volunteered to be crucified in the Glastonbury Passion Play in the attempt to atone for an unpardonable offence . . . right up to the end, till by straining his torso to the breaking-point he lost consciousness, he not only endured this anguish, but he exulted in enduring it. His exultation kept mounting and mounting—extreme pain and ecstatic triumph embracing each other in dark, mystic copulation."

Lastly, it is possible that pain may be deliberately sought in order to relieve a more distressing discomfort or sensation. Thus, the dull aching pain of a neuritis or an intolerable feeling of itching, tickling, or burning, may perhaps be assuaged only by the distraction of sudden fresh sensory impulse, even though painful in character. This phenomenon is, of course, common in normal subjects, and may well be of more frequent appearance among the insane.

The Factor of Attention

An interesting psychological point is raised by the question of expectation. Is a sudden and unexpected painful impression more intolerable than a stimulus of equal intensity falling upon an expectant subject?

Here there is probably an individual factor. In some persons no doubt a pain which comes suddenly and unexpectedly produces a reaction in which shock and discomfort are so intermingled as to outweigh the sensation which would succeed an anticipated stimulus. We know that in the case of electric shocks the factor of surprise is extremely important, the ill-effects being less when the shock is anticipated. There is a much-quoted case of a man who used to suffer deliberately a current of 500 volts. One day he accidentally made contact with this same current and was killed.

On the other hand, there are individuals whose dread of pain sensations is so great that the apprehension of an approaching stimulus greatly outweighs the effect of the pain when it arrives.

Hugh Walpole has expressed this admirably: "Only once or twice in his life had pain actually come to him. He did not mind it so deeply were it part of an illness or natural causes, but the deliberate anticipation of it—the doctor's 'Now look out; I am going to hurt!' the dentist's 'I may give you a twinge for a moment!'—these things froze him with terror. During the war, when he had offered his service, this was the thing that from the clammy darkness and the night leapt out upon him. . . . There had been times at the dentist's and one operation. That operation had been a slight one, but it had involved several weeks of the withdrawing of tubes and the probing with bright, shining instruments. Every morning for several hours before this withdrawing and probing he lay panting in bed, the beads of sweat gathering on his forehead, his hands clutching and unclutching, saying to himself that he did not care, that he was above it, beyond it. . . . but closer and closer and closer the animal came, and soon he was at his bedside, and soon bending over him, and soon his claws were upon his flesh and the pain would swoop down, like a cry of a discoverer, and the voice would be sharper and sharper, the determination not to listen, not to hear, not to feel weaker and weaker, until at length out it would come, the defeat, the submission, the scream of pity." Later, again: "The sense of the coming pain had been more awful than anything that he could have imagined. . . . One night earache attacked him. It was a new pain for him, and he thought that he had never known anything so terrible. Worse than all were the intermissions between the attacks and the warnings that a new attack was soon to begin. That approach was what he feared, that terrible and fearful approach. He had said very little, had only laid there white and trembling, but the memory of all those awful hours stayed with him always."

Yet another problem concerns the effect of one pain upon another. Is the net result of two simultaneous painful sensations the algebraic sum of two components? Or does one disagreeable sensation aggravate the other? Thus, does toothache feel worse to a normal person than to one already suffering some other painful malady—for example, sciatica?

Hippocrates stated: "Of simultaneous pain in two places, the lesser is obliterated by the greater." This dictum is illustrated, of course, by the fortitude which victims of severe and prolonged pain may show under

surgical attention. A patient with trigeminal neuralgia endures the pain of an alcoholic injection better than a healthy individual. This axiom of Hippocrates is only partly true, however, because much depends upon the quality of the pains concerned. A nagging or dull pain may so occupy the sufferer's attention as to render him irritable, apprehensive, and hypersensitive to fresh painful stimuli.

We know little as to the limits of human suffering, but we are perhaps justified in believing that when an intense painful stimulus is maintained for extreme periods of time, or steadily increased in intensity, there does not result a corresponding increase in pain feeling. In other words, a point is reached which transcends pain, and beyond which suffering becomes more tolerable. Little or no precise information is available as to the existence of such an adjustment, and the problem is one which to-day belongs more to the sphere of philosophy.

H. G. Wells ranks among the very few who have devoted thought to this problem. In *The Research Magnificent* we read of the elaborate mental exercises by which Beham strove by the deliberate overcoming of fear and pain to attain the "aristocratic life" or the "life set free." "He was clearly suggesting that in pain itself, pain endured beyond a certain pitch, there might come pleasure again, an intensity of sensation that might have the colour of delight. . . . He argued, we exaggerate the range of pain as if it were limitless. We think if we are unthinking that it passes into agony and so beyond endurance to destruction. It probably does nothing of the kind. And following on this came memoranda on the recorded behaviour of martyrs, or the self-torture of Hindoo ascetics, of the defiance of Red Indian prisoners. These things are much more horrible when we consider them from the point of view of the easy-chair. . . . are they really horrible at all? Is it possible that these charred and slashed and splintered persons, these Indians hanging from hooks, have had glimpses through great windows that were worth the price they paid for them?"

Asymboly for Pain

Brief reference may be made to a variety of agnosia described by Schilder and Stengel. As the result of a local cerebral lesion, situated probably near the left supramarginal gyrus, a localized or a universal indifference to painful impressions may develop. The disability cannot be described as a "loss" of sensation because certain milder stimuli are still perceived, and also because its distribution does not correspond with that found in cases of focal damage to the sensory pathways. The defect is a higher one in the sense that it entails factors of inattention and of imperception.

Relief from Pain

We have no words in English to signify that state of mind which follows the cessation of a severe or protracted painful experience. "Pleasure" is obviously not the word required, as it suggests a more positive state than that associated with mere stoppage of pain. It would therefore seem that relief from pain is a rather negative and affectless state of mind for which no adequate term is forthcoming. Exception may well be taken to this view, however, and one may perhaps submit that the emotional state following pain is one of relief, being essentially attended by definite—even if transient—physical and psychological gratification. The condition of *biensaise* immediately succeeding the emptying of an over-distended bladder or the slaking of a severe thirst instantly comes to mind. One recalls the reply of the lunatic who was asked why he was beating his head against the floor: "Because it feels so mighty fine when I leave off."

Some of the psychological concomitants of painful experiences may linger even after the pain has ceased. Literature contains various examples of this post-algic state.

Paley said: "Pain itself is not without alleviations. It may be violent and frequent, but is seldom both violent and long-continued, and its pauses and intermissions become positive pleasures. It has the power of shedding a satisfaction over intervals of ease, which I believe few enjoyments exceed."

Hugh Walpole writes in his novel *Hans Frost*: "I am suffering to-night from a toothache, and I have always noticed that a toothache is the most unintellectual pain in one's body, just as, in all probability, a stomach-ache is the most intellectual. Have you ever noticed, sir, how bright and clear one's brain becomes between the spasms of indigestion?"

Algoiphilia

The pursuit of pain as a pleasurable sensation may be encountered under various circumstances; to this phenomenon as a whole the term "algoiphilia" is applied. There are instances of this which are so commonplace as to be regarded as physiological.

A few examples may be quoted. Discomfort or pain may at times be courted merely in order to enhance the effect of a succeeding pleasurable sensation. One may compare this process with that technique in music whereby a discord is deliberately placed before a harmony for the purpose of contrast. Another common experience is that of probing or fingering a carious tooth or a wound. By such stimulation a dull ache may be converted into a sharper pain; it is noteworthy, however, that this type of stimulus is never applied to a severe or prolonged painful sensation. We have already mentioned that pain may be deliberately sought as a method of alleviating an intolerable dysaesthesia or even of distracting the attention from harassing psychological experiences. Lastly, it must be admitted that some degree of submission to pain is demonstrable in the female in relation to the opposite sex, just as a certain aggressiveness is a normal feature in the male. When, however, the degree of pain which is sought is excessive or prolonged, or is pursued as an end in itself, then the phenomenon transcends normality.

Four main types of morbid algoiphilia may be enumerated.

1. *Psychotic*.—Instances of the enjoyment of pain among the insane have already been discussed. It is necessary to satisfy oneself that there is no impairment of sensation in such cases.

2. *Racial*.—Among certain communities or races pain may be deliberately endured as a traditional practice. The Samurai of Japan, the Spartans, the Stoics, and the Paramahansas or nomadic Fakirs are cases in point. It is probable that in this group the pain itself is not desired so much as the accompanying virtues of fortitude, courage, and hardihood, which are deemed the spiritual counterparts. In this way Scaevola thrust his arm into the fire to demonstrate Roman endurance. At the flagellation dances of the Fulani young men bared to the waist call for volunteers to beat them with scourges, at the same time smiling, sneering, and taunting the flagellator. The young women bystanders are worked up into a frenzy of admiration, and tearing off their bead ornaments throw them at the feet of the victim.

3. *Religious*.—Self-abasement and the auto-infliction of pain find acutest among enthusiastic devotees of all manner of religious beliefs. We can trace here the associated idea of purification through ordeal of pain and fasting. Here again pain is desired, not for itself alone, but as a means to an end.

Last century Cornelius and Overbeck—two gloomy and eccentric pre-Raphaelite artists—used to prepare themselves for painting by flogging and fasts. In the same vein they eschewed the services of professional models, lest their canvas Madonnas should betray some undesirable traits of fleshliness.

If one may refer again to Hugh Walpole, we read how his Man with Red Hair, by suffering pain himself, had come to associate in his diseased brain the infliction of suffering with idea of power: "A good God, a sweet God, a kind

beneficent God. That is no God. God is first cruel, terrible, lashing, punishing. Then when He has punished enough, and the victim is in His power, bleeding at His feet, owning Him as Lord and Master, then He bends down and lifts the wounded brow and kisses the torn mouth, and in His heart there is a great and mighty triumph. . . . Even so will I do, so will I be . . . greater than God Himself."

4. *Masochism*.—The association of sexual stimulation or gratification with physical suffering or mental humiliation is a well-known phenomenon. It exists in some degree in normal individuals—characteristically the female when in association with the male. The attachment of a woman to a brutal and worthless husband, the fidelity of the prostitute towards the souteneur, are commonplaces which have been worn threadbare in literature. When accentuated, however, a definitely morbid phenomenon emerges. Although in some respects masochism is the complement of sadism—where pleasure is obtained from the infliction of suffering—yet the two states are often interwoven. Under obvious masochistic trends there often runs an overt or suppressed sadism. Even in the life and works of the Marquis de Sade masochistic traits are demonstrable. To express the idea of an ambivalent "sado-masochism" the term "algolagnia" is often applied. We owe the word "masochism" to the writings of a nineteenth century Austrian named Sacher-Masoch, whose imaginative flights largely concerned ideas of self-abasement and mutilation. In retrospect we can detect similar trends in earlier writers, as, for example, Aristotle, Thomas Shadwell, and Jean-Jacques Rousseau.

The well-known passage from the *Confessions* of the last may perhaps be quoted: "Mlle Lambercier . . . at times threatened to inflict upon us that childish punishment which we deserved. For some time she contented herself with threats, and that threat of a chastisement quite new to me seemed terrifying; but after its execution I found it less terrible in fact than in expectation, and the funniest thing was that this punishment endeared me still more to her who had carried it out. All the truth of my affection and all my natural docility was required to keep me from seeking more of the same treatment by deserving it, for I had found in the pain, even in the shame, a mixture of sensuality which had left behind more desire than fear of experiencing it again at the same hands. . . . The same punishment administered by her brother had no pleasurable effect. . . . The second occasion was also the last, for Mlle Lambercier, having no doubt noticed by some sign or other that this chastisement was not fulfilling its object, gave it up. . . . Hitherto, we had shared the same room, and, in the winter, even the same bed. Two days later I was made to sleep in another room."

A vein of masochism runs through much of the decadent literature of the nineteenth century. We find flagrant instances in many of Swinburne's works (*Lesbia Brandon*, *Our Lady of Pain*, *Tebaldeo Tebadei*; in Barrès' *Ennemies des lois*; and in D'Annunzio's *Forse che si forse che no*.

Pain and the Sexual Feelings

The mode of interaction of such apparently dissimilar phenomena as pain and sexual stimulation is of interest. Various ideas have been held upon this subject in the past. Some would ascribe masochism simply to the mechanical and reflex stimulation of the nervi erigentes by strong afferent impulses along the spinal segments. Others would invoke the general "tonic effect" of pain upon the organism (Féré). According to another viewpoint pain shares with the sexual orgasm the power of arousing strong emotion—whether of rage or fear—in greatest degree. Thus, André Gide describes how his extreme hypersensitivity, which used to distress him when ill with phthisis, would afterwards afford him exquisite enjoyment. Any very keen sensation, he concluded, might become a source either of delight or discomfort, according to the state of the general health.

Perhaps the most acceptable hypothesis is that of a conscious or unconscious association of ideas linking up certain pain stimuli with concepts or recollections of a sexual nature. These latter may be so intense as virtually to swamp the pain sensation and produce a temporary analgesia.

Havelock Ellis has discussed at length and with great clearness the probable mechanisms underlying the masochistic phenomena. He points out that in algolagnia the pain in question is less important than the violent emotional outburst; that the pain endured is never intense, and is usually, if not always, bound up with sexual activity; divorced therefrom, pain is no longer pleasurable. The sufferings experienced by a woman in association with sexual excitement may be gratifying in that they enhance the dominant and assertive characters which she appreciates in her male.

Krafft-Ebing summarizes the problem thus: "The person in a state of masochistic ecstasy feels no pain. When a woman says that she finds pleasure in the pain inflicted by a lover, she means that under the special circumstances she finds pleasure in treatment which would at other times be felt as pain. Or else that the slight pain experienced is so quickly followed by overwhelming pleasure that in memory the pain itself seems to have been pleasure, and may even be regarded as the symbol of pleasure."

PHYSICAL EFFICIENCY AFTER OPERATIONS FOR HERNIA *

BY

C. MAX PAGE, D.S.O., M.S., F.R.C.S.

SURGEON, ST. THOMAS'S HOSPITAL

The simple title of this discussion is, I think, no index of the extent of the subject. It certainly involves the primary consideration of the problems of detailed technique for the effective radical cure of various types of hernia; but in addition wider considerations, such as the bearing of age and the physical type operated on, repair processes in muscle, and aponeurosis, and recovery of body function, and the importance of the psychical element in this relationship must be included.

The practical surgeon will in the first place wish to determine what type of operation is most likely to be effective in producing a lasting cure in the individual case. Indeed, the successful closure of the hernial opening will generally be admitted as being of the first importance in restoring the physical efficiency of the patient. The types of hernia to be considered are inguinal, femoral, umbilical, and incisional and traumatic. A superficial examination of records shows that the incidence of inguinal hernia is much greater than that of any other type. For example, in five years' operations for hernia at St. Thomas's Hospital the approximate proportions were 11 inguinal hernias to 1.4 femoral and 1 ventral. I shall therefore take as my text inguinal hernia. I propose to analyse the published results of operation for this condition and refer to my own experience of it, leaving it to those who follow to fill in gaps and comment on my argument.

Treatment of Inguinal Hernia

The radical treatment of inguinal hernia will be admitted as having been on a sound basis since the introduction of Bassini's method in 1890. Since that date many modifications of technique have been put forward, and some have found a permanent place in surgical

practice. Bassini's method and the others that followed him were based on the principle of obliterating the sac and reinforcing, rather than reconstructing, the musculature which closes the inguinal canal. The next important advance was the use of the fascial suture or graft, a procedure which enables the surgeon in some degree to neglect the normal muscle closure of the canal and to substitute a fibrous diaphragm: this procedure is particularly adapted to the treatment of direct hernias, but its use for indirect hernias has advocates.

It might be thought that, in view of the amount of consideration given to the subject and the great bulk of cases which have been operated on, a common standpoint as to the best methods and their effectiveness would have been reached by now. This is, however, by no means the case. Inadequate or inaccurate information as to the late results of various operations is mainly responsible for this state of affairs. It is only in the last five or ten years that any systematic attempts to follow up hernia operations have been made. Even then in the figures resulting from such investigations one finds difficulty in assessing their proper value. The methods and standards of classification vary widely, and in all groups of figures there is a certain percentage of untraced cases which clearly weakens the value of any results arrived at. A further difficulty is that of estimating the value of new methods on account of the relatively small numbers reviewed and the shortness of the period of observation.

Assessment of Results

In discussions between surgeons on the end-results of hernia operations, the general impression to be gathered is that the individual surgeon using the method he favours seldom sees recurrences. No doubt there is a tendency for failures to be seen by surgeons other than those who first operated, but I cannot help thinking that a close and critical follow-up of all cases would show a much higher recurrence incidence than we believe to exist.

My own confidence in the satisfactory nature of results of inguinal hernia operations was shaken by my experience as consulting surgeon to the metropolitan police. Here we are dealing with a body of men some 20,000 strong, of picked physical efficiency, and young to middle-aged. The force, on the whole, is not exposed to excessive physical exertion. One would therefore expect a high standard of permanent cures after radical operations. The figures I have collected in relation to this group are small, but appear to be fairly constant each year. In the five-year period 1929-34 241 police officers were operated on for inguinal hernia. In 212 cases the operation was primary, the condition being double in fifteen. Four operations were for strangulated hernia. Twenty-five operations were for recurrences, which suggests an approximate recurrence rate of at least 11.5 per cent. In order to investigate the matter more fully I asked my first assistant, Mr. N. R. Barrett, to follow up and examine personally all cases of this type operated on at St. Thomas's Hospital for the previous five-year period. This investigation showed the incidence of recurrence to be even higher than this figure, and I will refer in detail to his findings later.

In the literature the most important statistical analysis of this subject is to be found in an article by Block.¹ He published in 1933 the collected results of 20,199 inguinal hernia operations. His figures were obtained from 650 different surgeons working in German clinics. The results he quotes are essentially of a bulk character, as he does not show the incidence of recurrence in relation to sex, age, or anatomical type of hernia. He himself recognizes that the estimate of recurrence varies with the individual observer. What one surgeon would term a weak inguinal region another would classify as a recurrent direct hernia.

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

None the less, the material considered is very large, and the figures resulting may be taken fairly to represent the present ideas on the Continent of the recurrence incidence. Of the total 20,000-odd cases reported only 6,029 were followed up for a period of two years or more. In this group 296 recurrences were reported. This recurrence incidence he analysed in relation to type of operation carried out, with the following result.

Recurrence Rate			
Method	Total Cases	Cases Followed	Incidence of Recurrence
Bassini ...	13,220	4,177	177 = 4.2 per cent.
Gerard ...	1,857	559	32 = 5.7 "
Kocher ...	1,533	221	7 = 3.2 "
Hackenbruch...	1,026	514	49 = 9.5 "

Results from smaller groups of figures are omitted.

He estimated the time of recurrence from personal investigation of 642 cases, the results being as follows:

Time of Recurrence in 642 Cases			
Inside three months	131 = 21.3 per cent.	
For next three months	109 = 16.9 "	
For next six months...	...	94 = 14.6 "	
One to two years	68 = 10.5 "	
After two years	224 = 34.8 "	
Unknown	16 = 1.5 "	

It is interesting to note that no less than 34.8 per cent. of recurrences occurred in this group after two years. In a large number of published cases the investigation has not been carried on sufficiently long after operation to include this group.

In the same group the cause of recurrence was put down by Block to the following factors in 548 cases in which the information was available:

Cause of Recurrence			
Suppuration or wound haematoma	122	
Pulmonary complications	79	
Technical errors in operation	27	
Double-sided operation	102	
Constitutional defect and poor connective tissue	149	
No observed cause	69	

Is Recurrence Avoidable?

Block states that in his opinion 40 to 45 per cent. of recurrences are avoidable, and emphasizes the important influence in this direction of a double operation carried out at one sitting. The nature of the recurrence in the group investigated is shown in the following table:

Situation of Recurrence			
Inner part of scar	286	
Outer part of scar	170	
Middle part of scar...	...	8	
Unknown	3	
Total	467	

Although it is of interest to discover the exact nature of a recurrence after an operation for indirect hernia, I find it very difficult from published records to come to any definite conclusion on the subject. Certainly the majority of recurrences are not properly oblique or into remains of the original sac. Block's figures suggest that the majority of recurrences are internal direct hernias, and that is consistent with my observations (from a clinical standpoint) in a group of policemen.

Another matter of interest and perhaps practical importance drawn from these figures is the routine period for which hernia cases are kept recumbent after operation, the following being the report from fifty-five different clinics.

Number of Clinics		Length of Stay in Bed	Period of Recumbency.
1	1 day
1	4 to 6 days
2	7 days
36	In second week
12	After two weeks
3	After three weeks

Block, though he finds no obvious ratio to exist between the period of post-operative recumbency and the recurrence incidence, makes the statement that, though the time of return to work varies considerably, it appears to be latest in those patients who get up soonest after operation.

An analysis of the suture material used in relation to the recurrence incidence suggests that it has little or no influence on the results. The figures are as follows:

Effect of Suture Material			
Material Used	Clinics Reporting	Cases	Recurrence Incidence
Catgut ...	36	7,980	4.3 per cent.
Silk ...	25	7,803	4.3 "
Thread ...	7	2,525	4.6 "
Silkworm ...	1	113	5.3 "

(The total death rate in this large group, excluding cases of strangulated hernia, was 0.5 per cent.)

Block was unable satisfactorily to determine the relationship of recurrence incidence to the experience of the operator. He notices in the cases of recurrence that the ratio of manual workers to sedentary workers is as 6 to 1.

Discussion

I have given in some detail the results of this investigation, as from the large number investigated they must carry considerable weight in forming a general surgical opinion in this subject. I should like, however, to emphasize certain criticisms as to their validity in assessing the recurrence incidence after operations for adult inguinal hernias. First, hernias in women and children are included in all results. By common consent the ratio of satisfactory cure in these cases is high. Secondly, only about three-tenths of the cases reviewed have been followed up, and of the group of 6,000 subjected to late examination few were traced for more than two years after operation.

From America the figures of Gibson and Felter² may be taken as representative of modern optimistic ideas. They conclude that in a group of patients numbering 1,618, the general recurrence rate is 2.9 per cent. For direct hernia they estimate it at 6.5 per cent., and give the astonishing figure of 1.3 per cent. for indirect hernias. It is of interest to note that they found the recurrence rate after double operations for indirect hernia to be 8.9 per cent. It should be noted that these figures were obtained from a quite inadequate follow-up; only sixty-seven cases were examined after two years.

Many reports of smaller groups of cases are to be found, most of them are designed to illustrate the results of some special technique. Bessin³ reports on 4,500 cases operated on by Kirschner's modification of Bassini's method. He followed up, in 1932, 267 male cases of all types operated on in 1928, and found ten recurrences (4.13 per cent.). Six of the recurrences appeared in patients in whom the wound had suppurred, or who had suffered from post-operative pulmonary complications. He noted that atrophy of the testicle was not observed in any instance. Ostfeld⁴ records 586 cases operated on by the Bassini

method, silk being used for preference as suture material; 239 cases were followed up, and the general recurrence rate was found to be 5.4 per cent. For indirect hernias the figures were 4.3 per cent., and for direct hernias 20 per cent. He noted that if the period of post-operative recumbency was limited to six days no increase in the recurrence incidence was noted. He finds that a hereditary influence doubles the likelihood of recurrence. Niessen's reports on 102 cases operated on by Schmieden's technique. In the sixty-six cases followed up there were six recurrences in men between the ages of 40 and 60. This method involves displacement of the cord, and it is worth noticing that in four atrophy of the testis followed, and that twelve cases complained of pain in the scar. I have not been able to find much in the way of figures from English sources. Turner and Eckhoff⁸ reported a small group in 1929. In ninety-eight cases simple excision of the sac was carried out, and gave only three recurrences. In twelve cases in which a modified Bassini operation was employed there were two recurrences.

An almost refreshing note in this welter of satisfactory results is sounded by Birkenfeld.⁷ He is concerned to show the association of hereditary tendency to the incidence of recurrence, and in seventy-six males followed up found a recurrence rate of 28.49 per cent. I think that the average results in the adult male are better represented by this figure than those previously quoted, although it seems incredibly high in comparison with the previous figures. N. R. Barrett recently examined for me 206 policemen out of a group of 295 who had been operated on between 1925 and 1929. Their average age was 32.5 years. The follow-up varied from five to nine years. In this group the recurrence incidence was 20.2 per cent. for indirect hernia, and 25 per cent. for direct. The average age of the men concerned was 31. In seven cases the recurrence appeared four or more years after the primary operation. In the forty-seven cases of recurrence bilateral hernia had been present and was operated on at one sitting. It may be noted that physical efficiency of many of the men was not sufficiently affected by the recurrence to prevent them carrying on with their duty. Twenty-six of the forty-seven came into this category, and of these only fourteen were wearing a truss.

Use of Fascial Suture

The use of autogenous fascia for suture was introduced, I believe, in 1904 by McArthur.⁶ The method has been elaborated by several authors, but now the technique introduced by Gallie and Le Mesurier⁹ appears to be the most satisfactory. The articles written in relation to this technique are multiple in number, but lack weight in the proportion of cases followed up for any length of time. The reason for this is probably that the fascial graft operation is reserved by most surgeons for direct, difficult, or recurrent cases. The theoretical case for the regular use of fascial sutures is put forward by Seelig and Chauke, and supported by Koontz. The latter thinks that preserved fascia is as efficient as fresh. They have shown that in reconstruction operations in the abdominal wall muscle and fascia sutured together with ordinary material do not unite. Koontz agreed to this, but states that if surfaces are first eroded union may be effected. This subject is reviewed by Hodgkins.¹¹

Of the figures bearing on this technique those of Gallie and Le Mesurier, published in 1930,¹⁰ may be noted. In 200 operations on direct and large indirect hernias they noted only four recurrences; all these recurrences appeared in bilateral cases. Lyle¹² reports on 159 bilateral cases followed for from one and a half to five and a half years on 132 cases operated on by the McArthur method and twenty-seven by Gallie's. He found 3 per cent. of recur-

rences in indirect hernia and 9.5 per cent. in direct. He states that in a group of operations carried out in the same period with catgut the recurrence incidence was twice as high.

Conclusion

I feel I have been guilty of firing off a lot of statistics, and when I come to an end I really do not quite know what I want to prove. The astonishing difference between the results that are indicated by these figures can hardly be laid at the door of any special technique. My own conviction is that recurrence after operation in the young to middle-aged is commoner and more difficult to avoid than we are inclined to think. When we come to consider how results are to be improved we are on thorny ground. The factors influencing success may be considered under the following headings:

1. Technical method.
2. Failures in technique, including suppuration and haematoma formation.
3. Post-operative pulmonary complications.
4. Operation on double hernias.
5. Hereditary tendency to hernia, or congenital feebleness of the musculature.

As opener of the discussion I shall refrain from commenting further on these points, as those who follow me will no doubt have clear ideas as to how some, at any rate, of these various pitfalls may be evaded.

Femoral and Ventral Hernia.—I have spent so much time on inguinal hernia that I shall only refer briefly to femoral and ventral herniae. I take it that in considering the closure of the femoral canal discussion will mainly range round the question of closing the femoral canal from above or below. I confess to belonging to the old-fashioned group, which thinks that a closure from below by Langenbeck's method gives as good results as any. I take it for granted that the stump of the sac is satisfactorily reduced within the abdomen, and that the crural canal is cleared of fat before the pectinal fascia is sutured to Poupart's ligament. I admit the apparent attractiveness of the upper shuttle type of operation, but remain unconvinced that it is the better routine procedure. The association of femoral with inguinal hernia is sometimes emphasized. No doubt, if at an operation for inguinal hernia Poupart's ligament is forcibly pulled upwards the crural canal is opened to some degree. The subject is elaborated by Hodgkins.¹¹ In a group of ventral hernias, whether they be umbilical, epigastric, or incisional, I think the operation must be worked out for the individual case. I confess my belief in the value of certain principles. They should be closed by fascia without undue tension, unless muscle is sufficiently adjacent to repair the gap without it being necessary to pull it out of its normal line of action. A fascial repair should be effected by a double overlap. When tension does not admit of this a fascial graft suture should be employed.

I trust that if my primary presentation of this subject was too paralytically statistical my final categorical statements will prove useful material for discussion.

THE PROLAPSE SYNDROME*

BY

A. C. PALMER, F.R.C.S.

GYNAECOLOGIST AND OBSTETRICIAN, KING'S COLLEGE HOSPITAL

Briefly, the term "prolapse syndrome" means prolapse associated with excessive bleeding from the cavity of the uterus. Different women present differing forms and degrees of prolapse, but the common form consists of a cystocele and rectocele, with deficient perineum, and more or less descent of the cervix, accompanied by a hernial protrusion of the pouch of Douglas. When on straining the cervix protrudes for an inch or more from the vulva, the form of the prolapse becomes typical of that denoted by the term.

In the early part of this century removal of the uterus by the vaginal route was almost wholly abandoned in favour of the abdominal route. This change was partly due to the fact that gynaecologists were becoming surgeons rather than physicians, and partly because in a large number of cases abdominal hysterectomy is obviously the method of choice.

In 1919 I saw vaginal hysterectomy performed a few times with mild surprise. During the next few years it was less rare, and I saw it often enough to learn a technique and suspect that there might be occasions when it had some advantage over the abdominal method: advantage from the point of view of its being less exhausting to both patient and surgeon. To the eye of one accustomed to the abdominal approach vaginal hysterectomy seemed a kind of fiddling, delving in the dark, affair—a cobbling up of tissues with little resemblance to ordered surgical procedure. In the course of experience this impression became modified, and one was surprised to find that the steps of the technique naturally followed each other in a simple and orderly manner.

During this period it became my portion to operate on a number of 14-stone patients possessed of an enlarged uterus, the "adipose sporan,"† varying degrees of prolapse, and complaining of excessive bleeding, accompanied by such general impairment of physical capacity as merited hysterectomy for its cure. These cases were dealt with by the abdominal route, the three or more inches of subcutaneous fat and the "sporan" making the opening and closing of the abdominal wall, in itself, an operation of some difficulty. The subperitoneal fat and the heavily laden omentum further narrowed the approach to the uterus, partially obscuring landmarks and impeding the satisfactory application of ligatures. The majority of the patients sustained a fair amount of shock and passed through a stormy post-operative period. In some, mild suppuration occurred in the subcutaneous fat, wounds broke down, to heal finally by granulation; a few left the hospital with incipient incisional herniae, while two patients, including one of mine, burst their abdominal wounds about the twelfth day after operation, depositing the intestines in the bed. These were re-sutured immediately, and in due course recovered. There was great difficulty in finding anything in the way of separate layers for suture, the cut surface on each side being fused into a solid mass.

Being now free from bleeding, these patients, in the course of time, regained some of their former energy and physical enterprise, and began to notice their disability from prolapse. Some reappeared complaining of dragging pain, of something coming down giving difficulty

in walking, or of stress incontinence of urine, and asked for relief. They required anterior colporrhaphy and posterior colpoperineorrhaphy, or, more briefly, reconstruction of the pelvic diaphragm, and in the case of some, whose former operation had been a subtotal hysterectomy, a hypertrophied actively discharging cervix required removal as well. A few required belts or further operation for their incisional herniae.

Remembering that these patients had already spent an hour on the operating table, experienced a stormy post-operative period and been three weeks or more in hospital, it seemed unsatisfactory that they should now reappear demanding another operation for part of their original complaint, and in a few cases further surgical treatment as a result of the former abdominal incision. Of course one knows that incisional herniae are sometimes unavoidable; but they are particularly liable to occur in the fat abdomen. This question of herniae, while being of interest, is secondary to the main consideration—that of a second operation for the treatment of part of the original complaint. The reconstruction operation being done, the patients spent on the average another three weeks in hospital, and returned to their vocations after a further period of two or three weeks' convalescence.

A Combined Operation

In thinking about this matter the question naturally arises: "Why not do a vaginal hysterectomy and combine it with the reconstruction operation?" There did not seem to be any very obvious objection, except the general consensus of opinion that vaginal hysterectomy formed no part of the operative treatment of prolapse, and was in fact contraindicated on the ground that in removal of the cervix one lost a stable suture point for the anterior vaginal mucosa. This reason I personally was unable to appreciate, because in order to render the cervix stable it had first to be hitched up in the pelvis by shortening the lateral ligaments, and further, in many cases, owing to hypertrophy and discharge, the greater portion of the cervix had to be removed as part of the reconstruction operation. The presence of the infected cervix might offer a further objection to opening the abdomen from below, or to the making of free vaginal incisions in its neighbourhood, and for some time this consideration made one hesitate to combine the two operations. On the other hand, amputation of the cervix is combined with repair operations, and here the infected cervix is actually incised, whereas in hysterectomy the incisions are not made in the cervix, but in relatively healthy adjacent tissue, even further away from the actual cervix than in the abdominal route; moreover, the condition of the cervix can be improved before operation by suitable douching.

With these considerations in view I began tentatively to combine the two operations, and up to the present time have found the procedure satisfactory to the patient and surgeon in suitably selected cases—namely, those whose symptoms and physical signs are denoted by the term "prolapse syndrome." This term, while including the prolapse sign and symptom complex, is meant to have a wider application, and extend to those patients who have an enlarged or retroverted uterus, or both, and complain of excessive bleeding, the condition of the uterus being such as to render practicable its removal from below.

Common Prolapse Symptoms

1. Girdle-ache, including sacral backache and dragging pain in the inguinal regions.
2. A sense of discomfort from something coming down in the perineal region.

* Read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

† Adipose sporan: A fold of abdominal skin and subcutaneous fat which rolls down over the symphysis pubis.

3. Frequency of micturition, varying in degree up to stress incontinence.

4. Irritation from excessive cervical discharge.

5. Undue fatigue at the end of a routine day.

Perhaps the outstanding feature is a sense of diminished physical capacity; the patient can now undertake only with difficulty and resultant fatigue what she formerly accomplished with ease. The ordinary daily round of household and social duties produces exhaustion. This state of affairs is due partly to anaemia and partly to the discomfort and other disturbances arising from prolapse.

These symptoms combine to reduce the patients' physical capacity, and make them unwilling to undertake the discomfort of walking or other forms of activity. Other difficulties arise in the later stages of prolapse, but these need not concern us here. A number of multiparae—it is not possible to give percentages—with prolapse have, in addition to their hypertrophied cervix, an enlarged uterus, which may be retroverted. The enlargement of the uterus may be due to a chronic subinvolution, to multiple small fibroids, rarely to diffuse adenomyoma, or even carcinoma of the body; these conditions give rise to excessive bleeding, and are therefore suitably included under the term "prolapse syndrome."

Conditions Necessary for Easy Performance of Vaginal Operation

1. The uterus and appendages must be mobile.
2. The uterus must not be too large or associated with large tubal or ovarian swellings.
3. The uterine disease must be such as not to contraindicate its removal from below—that is, carcinoma of the cervix.
4. The cervix should come down readily to the vulva.
5. The vaginal outlet should be relaxed, or at least easily enlarged by a relatively small incision, something considerably short of the old Schuchardt's* incision.

Quite often these patients have the fat, more or less pendulous, abdomen, already referred to as unsuitable for abdominal incision.

TECHNIQUE OF THE OPERATION

Five operative procedures are combined: (1) anterior colporrhaphy, (2) vaginal hysterectomy, (3) reconstruction of the hernia of the pouch of Douglas, (4) posterior colporrhaphy, (5) perineorrhaphy.

I will briefly describe a standard method of linking these procedures.

1. Preparation of the field: the perineum is incised back to the anal margin. The nymphae are sutured to the thighs and traction sutures are inserted in the cervix. Determine area of vaginal mucosa to be removed: (a) of the anterior mucosa, inserting landmark suture to mark the upper end of the new anterior vaginal wall; and (b) of the posterior vaginal mucosa, inserting landmark sutures at the site of the upper end of the new posterior vaginal wall.

2. Removal of redundant tissue; the anterior and posterior mucosa and the uterus in one technique.

3. Reconstruction of the pelvic diaphragm. Fix the uterine stumps and ovario-pelvic stumps on either side to the upper margin of the new lateral vaginal walls. Join the cut edge of the peritoneum of the utero-vesical pouch to the anterior landmark sutures, thus forming the upper end of the new anterior vaginal wall.

4. Reconstruction of the anterior vaginal wall.

5. Remove the redundant peritoneum of the hernia of the pouch of Douglas and suture the peritoneal stumps to the

posterior landmark sutures, thus forming the upper end of the new posterior vaginal wall.

6. Reconstruct posterior vaginal mucosa and the perineal body.

The operation in my hands requires an hour to an hour and a quarter for its performance, without undue difficulty in the control of unexpected oozing. There is, as a rule, no appreciable shock, and the patients do not have a stormy post-operative period. In general they are sitting up the next day, ready to do justice to their dinner. Towards the end of a week there is usually some vaginal discharge, which clears up readily with douching. The length of stay in hospital and the after convalescence period is the same as that for simple repair operations.

ADVANTAGES OF THE METHOD

1. The avoidance of two operations and the prolonged period of convalescence associated therewith, approximately five weeks instead of ten.
2. The avoidance of an abdominal incision in fat women and the possible post-operative complications.
3. The relative absence of post-operative shock.

I have looked up the notes of sixty cases. In all, the anatomical result* at the time of departure from hospital was good and the patients' general condition satisfactory. As far as the evidence goes at the moment this procedure would seem to be an improvement on the older method of two operations at different times by different routes.

Forty-four patients have been examined twelve months or more after operation, and fifteen three months or more. The anatomical result* was good, but in one case the posterior fornix, owing to imperfect fixation, bulged down to the outlet on straining, as a hernial protrusion. This gave rise to some discomfort, and has been repaired with success. Sixteen out of the sixty cases had post-operative *B. coli* cystitis, but in eight of these it was known to be long-standing. There were four slight secondary haemorrhages: one on the seventh day, and three between the tenth and twelfth days. Two patients had small abscesses in the perineum, which cleared up.

One case proved fatal. This happened in a mentally deficient woman who, by means of her fingers, removed the perineal stitches, became septic, and ultimately died from a pulmonary embolism. It is unfortunate that we were unable to recognize this woman's mental condition previous to the operation, for failure to do so has impaired what might otherwise have been an unblemished record.

* Good anatomical result.—The new vagina and perineum approximate to the nulliparous condition, the vagina admitting two fingers with some discomfort and No. 5 vaginal dilator without discomfort. There is no pouting of vaginal walls on straining, and no incontinence of urine on coughing.

With the object of promoting biochemical studies and research a Biochemical Society has been formed in Calcutta, and was formally inaugurated on July 6th at the All-India Institute of Hygiene. The first committee of the society has been composed of the following: Professor N. M. Basu, Lieut.-Colonel T. C. Boyd, Professor S. Ghosh, Professor J. N. Mukherjee, Dr. B. B. Sen, Professor H. K. Sen, Professor H. E. C. Wilson, with Dr. B. C. Guha as honorary secretary and Dr. B. Ahmad as honorary treasurer. It has been arranged to hold monthly meetings for biochemical discussions and reading of original papers. Four meetings have already been held, in which the following papers have been read: B. Ahmad, "The Metabolism of Carotene"; A. C. Roy, "A Purified Vegetable Medium for the Cultivation of Micro-organisms"; S. L. Banerjee and H. K. Sen, "The Catalytic Activation of Diastase"; A. R. Ghosh and B. C. Guha, "Vitamin C in Indian Foodstuffs"; K. C. Bhattacharjee, "Snake Venom and its Therapeutic Applications."

* Schuchardt's incision: An incision starting in the left vault of the vagina and passing deeply on the left side of the anus through the levator ani to the sacrum.

CYCLOPROPANE ANAESTHESIA

BY

W. STANLEY SYKES, M.B., B.Ch.

ANAESTHETIST TO THE GENERAL INFIRMARY AND TO THE
HOSPITAL FOR WOMEN, LEEDS

In 1929 Henderson and Lucas of Toronto¹ began to use cyclopropane on laboratory animals as an anaesthetic. A large amount of experimental work was done, both at Toronto and at Madison, Wisconsin, before the new gas was first used clinically by Dr. Ralph M. Waters of Madison and Dr. A. E. Guedel of Los Angeles.²

Description

Cyclopropane is trimethylene ($\text{CH}_2\text{CH}_2\text{CH}_2$), an isomer of propylene ($\text{CH}_3\text{CH}=\text{CH}_2$). It is heavier than air, with a density of 1.46, and is inflammable and explosive in concentrations of from 20 to 75 per cent. when mixed with oxygen. This is of no practical importance, owing to the closed circuit method of administration. At present it is made only by the Ohio Chemical Company, Cleveland, and is put up in fifty-gallon steel cylinders at a pressure of seventy-five pounds to the square inch. Its cost is still very high—25 dollars for fifty gallons. Including cost of carriage, insurance, cylinder purchase, and Customs duties, my own supply worked out at about 3s. a gallon, but fortunately (as explained later) very little is used per case. The gas is colourless, with a sweetish odour, not unlike chloroform or ethylene.

Clinical Results

The gas is not irritating to inhale, induction being smooth and rapid; but if too high a concentration is administered at first there may be some laryngospasm. It does not cause salivation like ether, and it is rapidly eliminated, consciousness being recovered quickly. Shackell and Blumenthal³ report that a monkey with advanced tuberculosis underwent anaesthesia five times, lasting upwards of six hours on each occasion, without apparent ill effect. Deep anaesthesia with good relaxation can be obtained, and the respiration is very quiet and shallow, but it is not certain how much of this is the effect of the gas itself and how much is due to the absence of carbon dioxide from the rebreathing bag. Clinically, the anaesthesia resembles that of chloroform, but the induction and recovery resemble that of nitrous oxide or ethylene.

It is, of course, premature to express any opinion yet, but cyclopropane appears to be a most promising anaesthetic, and it may possibly fulfil the hitherto unattained ideal of the safety and speed of nitrous oxide combined with the calm and quiet relaxation of chloroform. Dr. Waters, who knows more about it than anyone, is careful to avoid exaggerated claims until the anaesthetic has been very extensively tried out.

The gas causes little, if any, change in the blood pressure or blood chemistry, and it possesses the desirable feature which makes ether so popular—that is, in cases of overdosage the respiration fails before the heart. Animal experiment shows that cyclopropane anaesthesia deliberately mishandled by cessation of the oxygen supply can be taken to the stage of profound asphyxia and complete stoppage of respiration, which may be allowed to continue for six minutes before any effect is shown on the electrocardiograph tracings. If the administration is then stopped, rapid and spontaneous recovery takes place.

Method of Administration

Cyclopropane cannot be administered like nitrous oxide because of the prohibitive cost of such a wasteful method. Fortunately, like nitrous oxide and ethylene, it is excreted by the lungs unchanged, and is also unaffected by soda lime, so that the closed circuit carbon dioxide absorption method can be used. The sole function of the vast quantities of nitrous oxide used in a prolonged administration is to allow the patient to get rid of his carbon dioxide. If this is absorbed by soda lime, and oxygen is supplied in sufficient quantity for the metabolic needs of the body, the original bagful of gas may be used over and over again.

An air-tight cushioned face-piece is used, which can be strapped tightly on to the patient's head, and to which is attached a canister of granulated soda lime; through this the patient breathes into a rubber bag. The soda lime granules are kept in position by a wire gauze diaphragm at each end of the canister, and the bag or face-piece has a tube attached for the admission of cyclopropane and oxygen. All joints must be air-tight. The gases are delivered through flow-meters or a water sight-feed bottle. Cyclopropane is of about the same density as carbon dioxide, and can be used with a flow-meter calibrated for that gas. Before beginning, one should blow through the canister to remove any dust.

The harness is placed under the patient's head, the face-piece, canister, and bag fitted together, and a stream of oxygen turned on. The patient is then allowed to breathe into the apparatus, and the cyclopropane is turned on—very slowly at first and then more quickly. In a short time the harness is fastened on to the face-piece, and the head turned to the side, so that the canister rests on the pillow. After three or four minutes, when the desired depth of anaesthesia is reached (the signs are much the same as with ether), the cyclopropane is shut off altogether and the oxygen flow adjusted so as to keep the bag just full. The position is then as follows. In the closed and air-tight circuit formed by the patient's lungs and the apparatus there is (or should be) the correct percentage of cyclopropane to ensure anaesthesia (9 per cent. for loss of consciousness, 14 to 16 per cent. for deep anaesthesia). The gas itself is breathed over and over again, and, in theory, need not be altered however long the operation lasts. The carbon dioxide exhaled by the patient is removed by the soda lime, and the oxygen absorbed is replaced by the inflow from the cylinder. It is a curious spectacle to see a prolonged anaesthesia carried out with nothing more than a trickle of oxygen.

During a long operation it may be necessary to add a small amount of fresh gas to compensate for any loss by leakage or by diffusion through the rubber bag or through the patient's skin. All anaesthetic gases diffuse through these two membranes, cyclopropane considerably more easily than the others. The ordinary-sized canister, containing about a pound of soda lime, will last upwards of six hours before refilling is needed. The time will vary according to the type of patient. It will become exhausted more quickly when used for exophthalmic goitre cases, which have a high basal metabolic rate. Exhaustion is indicated by deepened breathing caused by the accumulation of carbon dioxide. (Siebe Gorman and Co. now market a brand of soda lime which changes colour as it approaches exhaustion point.) During use the canister gets warm from chemical action, but never too hot. Excessive temperatures might be reached if CO_2 were added to the circuit from outside, so if this is to be done the canister should be removed for a time. But it is one of the advantages of the method that the breathing is so quiet, so it seems unnecessary to interfere with this by

adding carbon dioxide. As the patient is having about 85 per cent. of oxygen there is no difficulty whatever in maintaining a good colour.

Case Records

Personal experience of the drug in Leeds is at present limited to thirteen cases.

1. F. 41. Carcinoma of breast; 65 minutes; some delay in induction due to excessive caution; anaesthesia otherwise good.

2. F. 34. Dilatation and curettage; 20 minutes; delayed induction again; recovery period 2 minutes.

3. F. 33. Clearance of uterus; 18 minutes; again a slow induction.

4. F. 36. Simple amputation of breast; 28 minutes; quick induction; blood pressure before operation 126/90, after 124/80; pulse before 112, after 76.

5. M. 32. Inguinal hernia; 31 minutes; adult of good physique; blood pressure before 140/84, after 148/84; pulse 72, 72; cyclopropane was given for four minutes, then turned off, turned on again for a few seconds half-way through, because of slight movement; patient was able to talk three and a half minutes after the mask was removed.

6. F. 48. Radium to cervix; 15 minutes; quick induction.

7. F. 26. Dilatation and curettage; cautery of cervix; 17 minutes; quick induction.

8. F. 48. Hysterectomy; 1 hour 16 minutes; quick induction; relaxation very good; no swab needed for sewing up; blood pressure before 125/80, after 120/80; pulse 150, 104.

9. F. Oöphorectomy, appendicectomy; 1 hour 2 minutes; relaxation good; movement of leg in middle of operation owing to leakage; anaesthesia rapidly deepened; no swab needed for sewing up.

10. F. 29. Oöphorectomy; good physique; 49 minutes; rapid induction, with slight struggling; relaxation good; moving 3 minutes after mask removed; talking in 10 minutes.

11. F. 61. Incisional hernia; 1 hour 15 minutes; three-minute induction.

12. F. 56. Umbilical hernia; 1 hour 35 minutes; a bad risk; enormously fat; gas and oxygen not chosen for this reason; bronchitic, which made it desirable to avoid ether. It was hoped that cyclopropane would solve the problem. After one hour anaesthesia was unsatisfactory—straining during sewing up could not be overcome, so a change was made to gas and oxygen with secondary saturation. This patient died four days later from pulmonary embolism.

13. F. 50. Hysterectomy; after 35 minutes changed to ether, as good relaxation could not be obtained.

Conclusion

The apparatus used was somewhat of an improvisation, and apt to leak. At Madison, with apparatus specially built for the carbon dioxide absorption method, I saw hysterectomies and stomach operations performed with ease under cyclopropane, and saw no failures.

It must not be forgotten that cyclopropane is a powerful agent which will produce anaesthesia in low concentration, so that it must never be used with small proportions of oxygen in the same way that nitrous oxide and ethylene are used.

During the last twenty years the number of medical practitioners in France has increased from 16,200 to 27,500, a rise of 70 per cent., while the rise in population has been only two millions, or 2 per cent. The number in Austria is 8,806, of whom 4,952 live in Vienna. In Czechoslovakia in 1933 there were 20 per cent. more practitioners than in 1930, there being one doctor to every 2,046 inhabitants in 1930 and one to every 1,689 in 1933.

Clinical Memoranda

METASTATIC CEREBRAL TUMOUR WITH PERFORATION OF AN ACUTE GASTRIC ULCER

In view of the reawakened interest in the part played by neurogenic factors in the aetiology of peptic ulcer, the features of the following case are recorded.

A woman, aged 46, was admitted for carcinoma of the cervix, with obvious secondary deposits in the bones of the pelvis and in the glands of the groin and supraclavicular region. The general condition was, however, fairly good, but the protracted downward course which had been predicted was cut short by her sudden death a few weeks after admission. At necropsy a general peritonitis was found, due to the perforation of a small ulcer on the anterior surface of the pyloric segment of the stomach. There were secondary deposits from the cervix in the liver and the lungs, and the lymphatic glands of the abdomen and thorax were extensively involved. The most interesting feature of the case was the finding of a solitary intracranial metastatic deposit, the size of a golf ball, situated in the dura mater over the upper part of the left Rolandic area, adjacent to the superior longitudinal sinus, depressing the brain and eroding the overlying bone. Histological investigation confirmed the metastatic nature of this cerebral deposit. A microscopical section of the ulcer revealed the typical features of an acute lesion.

Cushing, in his well-known work, has detailed the clinical, pathological, and experimental evidence in favour of the neurogenic origin of peptic ulceration. It has been shown that stimulation of the parasympathetic in the hypothalamic region, at the medullary nuclei or along the descending fibre tracts, leads to gastric hypermotility and hypersecretion. If the stimulation is continued erosions and ulcerations of the mucosa are produced. If the neurogenic origin of peptic ulcer is accepted it is possible that in the case here recorded the influences at work may have been produced by cortical stimuli from the tumour, or by irritation of the peripheral vagus by the enlarged mediastinal glands.

AGRANULOCYTIC ANGINA IN A DIPHtheria CARRIER

The following case of agranulocytic angina is of special interest in that it occurred in a patient who was apparently a diphtheria carrier, and that, as it is not uncommon in Rhodesia to admit to hospital untreated European cases of diphtheria at the fifth to eighth day of disease with advanced membranous invasion of the fauces, pharynx, and nasal cavities, the diagnosis on clinical and bacteriological grounds was rendered the more difficult.

CASE RECORD

A European girl, aged 21 years, was admitted to the fever hospital with the diagnosis of faucial diphtheria, confirmed by a positive throat swab report. On admission (? third day of disease) the temperature was 104.4° F. and the pulse rate 120; the patient complained of intense frontal headache. Examination of the throat showed acute oedematous inflammation of the soft palate, with membrane covering both tonsils and extending forward on to the palate, and on one side invading the pharynx. The glands of the neck were not enlarged. The membrane was not typically diphtheritic, being of a yellowish colour, and the general appearance suggested an acute streptococcal throat, but the proved presence of the Klebs-Loeffler bacillus led to the diagnosis of a double infection. Diphtheria antitoxin 16,000 units was given intramuscularly.

Fourth Day of Disease—Patient toxic; temperature 104.6°, pulse 130, headache persistent; no change in throat. Blood film: no malaria parasites found, leucocytes difficult to find.

Nov. 17, 1934]

Throat swab taken on third day showed Klebs-Loeffler bacilli present, but streptococci in large numbers. In the morning 10 c.cm. of scarlet fever antitoxin was given intramuscularly, as experience had proved this to be of value in streptococcal infections in this district. In the evening a further 16,000 units of diphtheria antitoxin was given intramuscularly.

Fifth Day.—General condition the same; temperature 104.4°, pulse 136. Throat showed signs of improvement as the membrane was stripping, but general inflammation was still severe. Some enlargement of the glands of the neck was present. Further 16,000 units of antitoxin given.

Sixth Day.—General condition worse; temperature 104.4°, pulse 136. No sign of membrane in throat, but acute congestion persisting; glands *in statu quo*. Antitoxin 16,000 units given in the evening, as there was evidence of the membrane re-forming.

Seventh Day.—General toxæmia marked; temperature 104.4°, pulse 140. Thick yellow membrane had re-formed over fauces and palate; glands of neck more enlarged. Throat swab taken on the previous day showed no Klebs-Loeffler bacilli, and persistence of numerous streptococci. At 10 a.m. antistreptococcal serum 25 c.cm. and scarlet fever antitoxin 10 c.cm., made up to 100 c.cm. with saline, were given intravenously. Blood count: Total red blood cells, 4,210,000 per c.mm.; haemoglobin, 80 per cent. (Tallquist); colour index, 0.95; size of red blood cells, 7.32 microns; reticulocytes, 2 per cent. Total white blood cells, 600 per c.mm.; neutrophils *nil*, lymphocytes 88 per cent., large mononuclears 12 per cent., eosinophils *nil*, basophils *nil*.

The haematological findings confirmed the suggested diagnosis of agranulocytic angina, and explained the striking lack of response to serum therapy.

Eighth Day.—General condition much worse, with loss of consciousness; temperature 104.4°, pulse 140, weak. Throat condition showed membrane stripping, and marked glandular enlargement. It was decided to try blood transfusion, and though the requisite donor was obtained the patient collapsed, and death took place before the blood could be given.

Consideration of the details of this case leads one to the conclusion that the presence of the Klebs-Loeffler bacillus in the first place caused an erroneous diagnosis of membranous diphtheria with an accompanying septic infection, and that the correct diagnosis was agranulocytic angina with an incidental mild infection or "carrier" type of diphtheria.

My thanks are due to Dr. W. K. Blackie, the Government pathologist, for his invaluable assistance in the laboratory investigation of this case.

BILATERAL CONGENITAL MALFORMATION OF THE ELBOW-JOINT

The interesting feature of the case reported below, apart from its anatomical peculiarity, is the extremely good functional efficiency of the abnormal joints.

A domestic servant, aged 24, was admitted to the hospital on August 14th, 1933, and was under treatment for acute rheumatism in her ankles and knees. She made a satisfactory recovery in about three weeks. During her examination it was noticed that she appeared to have a marked prominence of both olecranon processes, which, she stated, had always been present. X-ray examination of the elbows showed a flattening and elongation of the head of each radius, which extended up over the capitulum, articulating with the humerus in much the same manner as the ulna. There was no evidence of fusion of the radius with the ulna, or of arthritic change in the joint, or bony rarefaction. The appearances were consistent with the presence of an articular surface between the extended surface of the radius and the corresponding surface of the humerus. Power and muscular development of both forearms was good, and the wrist-joint was normal. Extension of the arm at the elbow was limited about two or three degrees only, and there was a slight limitation of pronation and supination. There were no

abnormal movements or sounds in any position. The patient stated that she had never noticed any disability in using her arms. She was much below average height and development, and had had a double talipes varus in youth, which had been cured by operation.

Most recorded cases of congenital deformities of the elbow-joint are radio-ulnar synostosis, synostosis of the humerus with the radius or ulna, or congenital dislocation of the radius. In radio-ulnar synostosis the union is

usually at the upper end of the bones by a broad bony bridge which unites the adjacent borders of the bones. Pronation and supination are completely prevented. An example of this deformity is given by Steindler.¹

Cases of congenital synostosis of the humerus with the radius or ulna show more or less fusion of these bones with the humerus. Usually the ulna is affected, and often other congenital deformities are present. The deformity most often involving the radius is dislocation. This is of rare occurrence. Usually found in male children, its commonest form is a backward dislocation. The cases are often complicated by radio-ulnar synostosis.

Reviews

CLINICAL SCIENCE

To those who heard the inspiring Harveian Oration delivered by Sir THOMAS LEWIS at the Royal College of Physicians in 1933, of which his latest book¹ is a welcome elaboration, the title *Clinical Science* will cause no surprise. To others, however, there may be some uncertainty as to its meaning. This will be quickly dispelled by the opening chapter on "The Scope and Methods of Clinical Science," in which will be found a detailed exposition of the author's meaning, given with that fullness of thought and clearness of diction which characterizes all his writings. The book deals with a matter of the highest importance to all who have the future welfare of medicine at heart, and the views which it sets forth are those of a great and enlightened thinker who has devoted his life to the subject. It is the proclaiming of a faith which the author himself has practised. To him clinical science means no new thing, nothing distinct from the science and art of medicine. Indeed, it is very old. The science of Harvey was clinical science. So far from suggesting by this term anything distinct from medicine, the author's object in choosing it is to emphasize the necessity, not for a divorce or even a judicial separation between medicine and science, but for their closer and more intimate union. Harvey fought for "science" against "no science," for accurate observation against vague tradition. Times have changed since his day. There is no longer a fight between "science" and "no science." Indeed, there is no longer a fight at all, but rather a matter of friendly adjustment among fellow scientists. During recent times medicine has availed itself so fruitfully and to so wide an extent of the help of the laboratory workers in the ancillary sciences that the true position and the paramount importance of the clinician in medical research have been somewhat overshadowed, and are in danger of being overlooked. To-day the prayer of the clinician may well be, "Save me from my friends!"

To strengthen and illustrate the views it upholds, the greater part of the work is devoted to accounts of the many and varied clinical problems which the author and his fellow workers have studied, and in many instances solved, during the last twenty or more years. Each short chapter, in itself a complete and concise essay on one particular item of investigation, begins with a definition of the nature of the problem to be solved, and the possible methods of approach. We are shown where and what kind of difficulties arose, and how they were met. Each is completed by a clear and full summing-up, showing exactly how far each problem has been solved, or what stage in its solution has been reached from which future workers can take off with security. With most of the thirteen problems here so admirably epitomized the author's name is inseparably connected, so that a mere enumeration of them is unnecessary. They range from auricular fibrillation to Raynaud's disease, from angina pectoris to axon reflexes. The number in which a real solution has been reached is astonishing. The harvest has indeed been rich. At the end of each chapter is a convenient reference to the original publications.

Did the book contain nothing more than this wonderful collection of essays it would be enough, and more than enough, to satisfy the most exacting reader. Each of them, however, is here not for itself alone, but in order that it

may illustrate special points bearing upon the author's main theme. Whilst probably all will agree with the views which are here so ably advocated, opinions may differ as to the exact steps by which they may best be realized. It seems clear that if progress in this direction is to be made in the near future more whole-time clinical posts must be available at our hospitals, to which young men of high scientific training will be prepared to devote their lives—posts in which clinical research can be carried on not only with every facility which science can supply, but freed from the drudgery of class and office routine, or the intermittent calls of private practice.

To-day it is the word "clinical" which needs underlining. There are plenty of similar posts connected with the great medical schools throughout the country which are devoted to various lines of medical research, but most of them only deal with the margins of medicine. Its real centre is the bedside of the patient, and there, at the present time, research posts are far too few. In disease, as in health, "The proper study of mankind is man," and whilst for the purpose of such study every available help that animal experiment and laboratory investigation can give must be made use of, it is the clinician, and the clinician alone, who should be in control. It is our duty to see that the "clinical science" for which Harvey fought so long and so well does not pass into other hands, leaving little but the art of medicine for the clinician at the bedside.

A. J. H.

ACUTE INTESTINAL OBSTRUCTION

The problems of acute intestinal obstruction are varied and complex. Around them a vast literature has grown up, based on investigations into all the aspects of the subject—statistical inquiries, clinical, physiological, pathological, and experimental work. In his recently published monograph² Dr. MONROE A. McIVER had embodied all that is of importance in this large mass of facts and theories, welding them into a coherent whole, and the result may be regarded as a fair summary of our present knowledge of the disease.

The book is divided into three main parts. The first part gives a general textbook account of the subject, with a description of the various types of acute obstruction, their aetiology, pathology, and clinical features. The morbid anatomy, effects on the various bodily functions, mechanism of dehydration and electrolyte loss, changes in the blood plasma and body fluids, and the bearings of these on the clinical picture, are discussed in detail. Three chapters are devoted to the functional obstructions, with particular reference to the difficult subject of paralytic ileus. The second part of the book is concerned with methods of diagnosis and treatment, and contains much practical information. In addition to descriptions of the operative procedures appropriate to the various types of acute obstruction, pre-operative and post-operative care, the choice of anaesthetic, and the treatment of complications arising during and after operation are considered. The third part begins with a description of the different types of animal experiment that have been carried out, and an attempt is made to correlate experimental results with clinical conditions. The various theories of the cause of death are reviewed; the highly controversial questions of toxin formation, their possible sources, ways of absorption, and modes of action; the role of dehydration and of vasomotor shock.

The book has been written by one who is obviously a master of his subject. The large extent of the ground which it covers is indicated by the fact that there are

¹ *Clinical Science, Illustrated by Personal Experiences.* By Sir Thomas Lewis, C.B.E., F.R.S., M.D., D.Sc., LL.D., F.R.C.P. London: Shaw and Sons, Ltd. 1934. (Pp. 189; 49 figures. 12s. net.)

² *Acute Intestinal Obstruction.* By Monroe A. McIVER, M.D. New York: Paul B. Hoeber, Inc. 1934. (Pp. xviii + 470; 62 figures. 7.50 dollars.)

over eight hundred references to published work. Conflicting theories, and they are many, are dealt with impartially, the author reserving his personal views for a final chapter. His approach to the subject is modern and scientific, in that he always tries to explain phenomena in terms of underlying structural, functional, and chemical changes. Dr. McIver's monograph is likely to find a wide range of readers. Its special appeal will be to those who want to keep in touch with the most recent views on pathology and treatment without the necessity for very extensive reading.

BIOLOGY FOR THE GENERAL READER

Two of the criteria which should be satisfied by any modern book professing to give a general account of biology for intelligent but non-technical readers are: that it should deal with broad principles and the main characteristics which mark forms of plant and animal life rather than be built up round a description of various types; and that it should emphasize the importance of studying the reactions of organisms as complete units to their normal surroundings rather than the reactions of their various tissues and organs in a laboratory environment. These criteria are entirely satisfied by Professor YONGE's volume entitled *The ABC of Biology*.³ The author describes it as a somewhat experimental book, and it is, indeed, written on unusual lines. A number of types are, of course, described in illustration of general statements of biological facts and principles, but it is these latter which are the main theme of the exposition. As Professor Yonge says in his preface,

"Biology is something more than biochemistry and physics, than the application of the methods of chemistry and physics to the analysis of living matter. There is a biological point of view which is broader and deeper than the purely physiological point of view, although it must include this. It is impossible fully to explain the animal or plant as a whole by the analysis, no matter how detailed, of the constituent parts."

The book begins with an account of the nature and origin of living matter, and the distinction between plants and animals. Then follows an admirably clear and succinct description of the mechanisms of life—the accumulation, transport, and utilization of energy; reception, response, and regulation with respect to environmental conditions; reproduction, growth, and development. This section includes a suitable account of the nature and importance of enzymes, vitamins, and hormones, of the main points in the evolution of the heart, the organs of sense, and the brain; and an excellent statement of the functions of the chromosomes and the general principles of inheritance. The third chapter deals with the organism as a whole, its powers of adaptation to every variety of environment, the nature, causes, and general course of evolution, with a brief review of the classification of the animal kingdom. The last chapter has to do with the study of living things in nature. This is perhaps the least adequate part of the book, but it well stresses the importance of the subject, and contains a number of interesting examples of the reactions and associations of organisms. It would have been well, we think, to have amplified this section, and to have included a brief account of mental development in animals as shown by behaviour.

It can scarcely be a matter of complaint that the book is mainly concerned with animals rather than plants. The latter are referred to only in connexion with the general account of living matter, the experiments of Mendel, and their interactions with animals. The volume is not intended to be a textbook for students of

science or medicine, but it can be read by them with great advantage. The preparation of a textbook on similar lines to this, but with fuller material, would be a very valuable piece of work.

THE THEORY OF GYMNASTICS

New books on various aspects of physical education have increased noticeably of recent years. Among them there have been some characterized by a dullness and mediocrity which makes one doubt whether their publication could in any way further the subject about which they were written. Not so *The Theory of Gymnastics*,¹ by Professor JOHANNES LINDHARD. It can at once be said that this is a book which will greatly enrich the existing literature and refresh the reader by its enlightened approach to the study and practice of gymnastics. The author is professor at the Gymnastic Physiological Laboratory of the University of Copenhagen, and his country is noted for its progressive educational work. This translation from the Danish will be welcomed by many English-speaking people, and especially by teachers of physical education. It will make a particular appeal to women gymnasts, because it considers aesthetic as well as physiological principles.

A mistake that has been frequently made regarding gymnastics for women and children is that they are taught almost entirely the same exercises as men, but perform a feeble version of them. That many of these are unsuited to women's form is obvious on seeing the often ridiculous attitudes taken up by women drilling—for example, Red Cross workers. Professor Lindhard's discussion of age and sex differences is interesting, and makes a good starting-point for the design or modification of exercises intended for men, women, or children. In a later chapter he examines seriously the posture which is at present officially accepted as "correct," and which is so often exaggerated, ugly, and physiologically unsound. To support his views he contrasts this with those idealized in ancient Greek sculpture, and most readers will warmly agree with his conclusions. A great variety of exercises are given here, and these are classified as order, corrective and balance exercises, and exercises to be done in marching, running, or jumping. They will provide an ample store for the teacher in search of ideas for individual and class work. The delightful photographs of the balance and running exercises for women are all derived from Mrs. Bertram's gymnastics, and should convince gymnasts that to attain perfection in body development and movement an aesthetic outlook is not merely desirable but is a fundamental necessity.

If the ideals set forth in this book are striven for by teachers of physical education there is great hope for improvement of physique, strength with suppleness, and grace of carriage in future generations.

CHINA THROUGH A SURGEON'S EYES

Dr. ALBERT GERVAIS, formerly a medical officer in the French Navy, "heard the East a-calling" while serving abroad, and so secured his transference to the French Medical Mission at Cheng-Tu. In *A Surgeon's China*² he tells of his life in Szechuan, that great rich province (larger than France) in the south-west corner of China of which Cheng-Tu is the capital. Though the author's observations are original, there are no subjects in the book that have not often been described before in the plethora of volumes on China—the journey to Cheng-Tu,

³ *The ABC of Biology*. By C. M. Yonge, D.Sc. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1934. (Pp. 232; 50 figures. 4s. 6d. net.)

¹ *The Theory of Gymnastics*. By J. Lindhard. London: Methuen and Co., Ltd. 1934. (Pp. 259; 81 figures. 12s. 6d. net.)

² *A Surgeon's China*. By Albert Gervais. London: Hamish Hamilton, Ltd. 1934. (Pp. 303. 7s. 6d. net.)

civil warfare, Chinese social customs, and the account of a cholera epidemic. But he writes with ease and grace; he has the witty pen of the late Pierre Loti that carries the reader from page to page with pleasure. For medical men, especially those who have not practised abroad, his account of hospital and teaching work will be found most enlightening and interesting. Chinese mentality is in many respects so different from ours that the stay-at-home reader might well ask, "Can such things be?" Dr. Gervais's two attempts to teach his students anatomy by dissection of the human cadaver were in each instance thrilling. No one not gifted with resourcefulness and courage could have faced the ordeal in the successful way the author did. It is an informative book well worth reading, and the reviewer (who has spent a number of years in China) can add that it truly depicts the strange happenings that are a common experience of those foreigners who elect to live in the interior of that quaint and wonderful country.

Notes on Books

In her work entitled *Rhythm of Life** Mrs. SOFIE LAZARSFELD, who is in charge of a mental consultation bureau in Vienna attended by men and women of all social strata, but is not, as she informs us on page 303, a physician, deals with various sexual and educational problems from the point of view of the psychologist of Adler's school. The subjects discussed include monogamy and polygamy, the first sexual experience, the marriage of the professional woman, the development of woman's personality, and roads to sexual reform, with a record of illustrative cases.

Metastases and recurrences in bones arising from carcinoma of the female pelvic organs form the subject of a brief monograph by Drs. E. PHILIPP and G. SCHÄFER of Berlin.⁷ Diagnosis, symptoms, method of spread, and treatment are comprehensively dealt with. Those specially interested in this subject will find here a large amount of valuable information in a very small space.

The second volume of the forty-fourth series of *International Clinics*⁸ consists of three parts, concerned respectively with medical, surgery, and recent progress in obstetrics and paediatrics. To the first part Warfield T. Longcope of Baltimore contributes a paper on generalized oedema associated with disease of the gastro-intestinal tract, and illustrated by two cases associated with abnormally low plasma proteins due to amoebic and bacillary dysentery respectively. Thelma Lovett of Philadelphia reviews the pathogenesis of anterior poliomyelitis, and comes to the conclusion that most support, epidemiological and experimental, has been given to the nasopharynx as the site of inoculation, but that the route of invasion taken by the virus is the spinal cord has not yet been determined. Heredofamilial angiomatosis (telangiectasia) with recurring haemorrhages is the subject of a richly documented article by Hyman I. Goldstein. The surgical section contains papers on operative shock by Professor E. Rehn of Freiburg i/B.; operative collapse therapy in pulmonary tuberculosis by Ralph C. Matson and Ray W. Matson of the University of Oregon; indications for surgical treatment of peptic ulcer by I. W. Held and A. Allen Goldbloom of New York; on evaluation of our present knowledge of purpura haemorrhagica (thrombocytopenia) by R. L. Payne and R. C. Whitehead; and estimating the amount of disability by Earl D. McBride, as illustrated by records of seven cases, which emphasize the need of more careful primary examination so that an accurate diagnosis can be followed by adequate treatment. The obstetric and

paediatric section contains papers on the toxæmias of later pregnancy by Nicholson J. Eastman, and on immunization against diphtheria and scarlet fever by Lawson Wilkins of Johns Hopkins Hospital.

In his book *Oil and Wine*⁹ Mr. PHILIP INMAN once more proves himself a zealous advocate for Charing Cross Hospital, of which he is the managing governor. He tells his entertaining tale in an easy journalistic style, and knows the value of a good anecdote. Much of the book is devoted to the methods of raising money for the hospital, and Mr. Inman has proved himself a king of beggars in his efforts on behalf of Charing Cross. He even went to America to beg for money—and got it. It does not occur to him to question the excellence of a system that manages its finances thus, and he naively accepts a situation in which a London hospital has to woo American financiers in New York in order to pay its way. That Mr. Inman has been successful is all to his credit, and due, perhaps, to his innocence abroad. But one would have welcomed from his pen a criticism of the financial side of the voluntary hospital system, and of the haphazard and—to many people's minds—undignified way in which the hospitals in the richest city in the world have to be maintained. Mr. Inman has generously given the net profits of the sale of his book to Charing Cross Hospital.

The various supplements to the *Acta Radiologica* (Stockholm) form a valuable series of monographs upon subjects connected with radiology, and in the latest volume (No. XIV) Dr. THORÆUS makes a study of the ionization method for measuring the intensity and absorption of Roentgen rays, and of the efficiency of different filters used in therapy.¹⁰ The work, which is written in English, is necessarily of a highly technical character, and does not lend itself to detailed review in these pages. It is, however, of deep interest, fully maintains the high reputation of its author, and forms a most valuable contribution to the important subject of which it treats.

* *Oil and Wine*. By Philip Inman. London: Chapman and Hall, 1934. (Pp. 293. 8s. 6d. net.)

Preparations and Appliances

IODINE VAPOUR IN MAXILLARY SINUSITIS

Dr. A. R. FRIEL (London, W.1) writes:

Dr. W. A. Wells of Washington, D.C., published a paper in the *Laryngoscope* for October, 1932, on the use of a vapour derived from iodine and other substances in the treatment of suppurative in the maxillary sinus. The vapour is obtained by heating a powder containing iodine, boric acid, carbolic acid, menthol, cubebs, all four parts, and thymol one part. Mr. Weiss, chemist, of Tottenham, makes this up to 100 parts with kaolin. The apparatus used in America was electrically heated and costly, but Mr. Weiss has succeeded in supplying us with a pyrex glass container. About a teaspoonful of the powder is placed in this and heat is applied with a methylated-spirit lamp. The vapour is blown with bellows into the nose. I thought this treatment might be useful for some troublesome cases of rhinitis

which are not due to congestion of the inferior turbinates and retention of secretion in the lower nasal passages, but show infection in the upper nasal area. No ordinary treatment can be applied to the upper area of a child's nose, but this vapour seems to get there, judging by the disappearance of the discharge. The results in several cases treated in the Tottenham clinic were quite satisfactory.

The apparatus and powder can be obtained from G. F. Weiss, M.P.S., 160, Philip Lane, Tottenham, N.15.

British Medical Journal

SATURDAY, NOVEMBER 17th, 1934

DOSAGE OF VITAMIN D

It is a discouraging fact that, in spite of constant efforts to emphasize the need for the routine administration of some antirachitic material to infants and young children, rickets is still quite prevalent. In a recent article¹ a group of workers in Toronto from the university department of paediatrics and the Hospital for Sick Children report a study of the relative value of cod-liver oil, viosterol, and irradiated milk in the prevention of rickets. Altogether 529 infants were observed over a total period of five winter months. At the time of first observation (at well-baby clinics) the infants were divided by rotation into nine groups according to the antirachitic agent employed: the first group received one teaspoonful of cod-liver oil daily (a high-grade Newfoundland oil containing 130 Steenbock units of vitamin D per teaspoonful), the second two teaspoonfuls daily, and the third three teaspoonfuls daily; the fourth group received 100 units of vitamin D daily in the form of viosterol, the fifth 200 units, the sixth 400 units, and the seventh 800 units. The eighth group was given twenty ounces of irradiated, pasteurized cow's milk daily, any further milk being taken as ordinary pasteurized milk, while the ninth group had all the milk required up to a total of one quart as irradiated milk. There were also a number of infants as a control group who had no additional vitamin D in their dietary. All the antirachitic material employed was biologically assayed, and the infants were carefully examined clinically and by x-ray photographs of the wrists at the beginning, in the middle, and at the end of the period of observation, the same physician being responsible for all the investigations and an independent observer reporting on the x-ray films without being aware of the antirachitic material used for any individual case.

The infants were all under 8 months at the time of coming under observation, and for the purpose of discussing the results the authors divided them into two main divisions for each of the groups—namely, those under 4 months of age at the original examination, and those between 4 and 8 months. During the period of observation the babies continued to attend the well-baby clinics, where they received the antirachitic material free of charge, and two nurses (described as "exceedingly competent") visited the homes at least once a month. Dosage and administration of the antirachitic materials could scarcely have been better controlled. The results show that of 137 infants receiving one, two, or three spoonfuls of cod-liver oil three winter months, actually all three falling into the larger

dose groups (one had two teaspoonfuls daily and two had three). X-ray evidence suggested that, apart from these three exceptions, one teaspoonful was as effective as three in preventing rickets. The four groups having viosterol (186 infants in all) were all protected from moderate or marked rickets, and again the x-ray evidence suggested that 100 units of vitamin D in this form daily were as efficacious as the larger doses. The children who were given irradiated milk were likewise protected from moderate or marked rickets, and this had no relation to the amount (between twenty and forty ounces daily) taken. The x-ray examination included, besides the types already mentioned of moderate and marked rickets, two others classed as "very slight" and "mild" rickets, and it is a little difficult to follow the authors exactly in their final conclusions, which seem to a certain extent to ignore the development of these types. This is especially important in view of the fact that among sixty-five infants not receiving any special antirachitic treatment only five developed "moderate and marked" rickets, while fourteen were placed in the "very slight" category and ten in the "mild." It does, however, emerge from the study that irradiated milk presents the most practical way of ensuring a regular daily dosage of vitamin D, since the percentage of cases cancelled for unsatisfactory administration was lowest in this group. (It is important to note that pasteurized irradiated milk was employed, and the reliability of pasteurization in Toronto is well recognized. It would be a great mistake if this conclusion led to the use of irradiated raw milk in this country.)

The results in each individual group for each age division are unfortunately not numerous enough in each instance to make statistical analysis possible. It is still uncertain what is the minimum protective dose of vitamin D and the best means of giving it: Alfred Hess's last work before he died suggested that, on a basis of vitamin D potency, cod-liver oil gave best results, better than the irradiated ergosterol preparations. The Toronto work implies, however, that there is more chance of error in cod-liver oil administration. One aspect of the subject not touched on by the authors may be mentioned in conclusion. The cod-liver oil emulsions sold commercially or supplied by welfare centres in this country may vary in strength from 20 to 30, or, in rare instances, to 50 per cent. of oil, while the popular "cod-liver oil and malt" preparations usually contain only 10 per cent. of oil. The dosage of actual oil given daily when the preparation selected is administered in teaspoonfuls or fractions of a teaspoonful may only be a matter of minims. This may account for the continued prevalence of rickets, despite the greater use of antirachitic measures than ever before. The time is surely ripe for an investigation, on an even wider scale than the present one reported from Toronto, to settle by clinical trial, in terms of vitamin D, what is the minimum protective dose at each age period, and what is the best medium for its administration.

¹ Canadian Med. Assoc. Journ., October, 1934, p. 368.

RECENT WORK IN RADIOLOGY

Even a cursory glance at the proceedings of the fourth International Congress of Radiologists held at Zurich last June¹ will show how great has been the progress in this branch of science during the past few years. In the early days of x rays the same apparatus was used for diagnosis and for the very limited methods of treatment available. Now, however, not only do x -ray diagnosis and x -ray therapy form two separate branches of medicine, each of sufficient importance to occupy the attention of a single individual, but here again regional specialization in the near future seems to be by no means improbable. Added to this is, of course, the therapeutic use of radium, which is intimately bound up with high-voltage x -ray therapy. In the official book giving abstracts of the various papers communicated to the congress an enormously wide range of subjects is treated, under the general headings of x -ray diagnosis, radiotherapeutics (x rays and radium), biological action of radiations, physics, apparatus and allied subjects, electrotherapeutics, and heliotherapy, including ultra-violet radiation. It is impossible in a brief general notice to "review" this wealth of material in the ordinary sense of the word. All that can be done here is to select a few of the less known uses and results of x -radiation which may be of general interest.

Diagnostic problems we must leave to those specially interested; but in the field of therapy the reader will be struck with the enormous benefits that have resulted from the employment of radiation methods in malignant disease. Under the heading "Radiation Genetics" there is a great deal of material which provides food for very careful thought. As its name implies, radiation genetics is concerned with the action of radiations upon the germ cell, and the possible changes that may occur in the offspring as the result of irradiation of the genital glands of the parents. The most recent experimental results point to the need for caution in irradiating the ovaries of potential mothers, and special prominence is given to the possibilities of damage which may be transmitted beyond the first filial generation. To one who has studied the cytological appearances occurring after radiation, such injuries appear almost inevitable. In the paper included in the present collection attention is specially directed to chromosome changes; but when it is realized that probably all the cell elements—extranuclear as well as nuclear—can be modified by exposure to radiation, it is surely not too much to urge that the possibility of far-reaching damage should be borne in mind. In particular, it is not gross lesions in the immediate offspring of the irradiated parent which have to be considered, but the possibility of such irradiation giving rise sooner or later to conditions of diminished well-being physically and possibly mentally. As regards the latter, animal experiments, valuable though they are in many ways, can hardly be regarded as conclusive when the higher mental

faculties are under consideration. The need for intensive study and careful recording of results in future generations as time goes on is of paramount importance. Essentially the end-result of the action of intensive radiation upon any cell is to damage it. In the case of neoplastic cells this is, of course, the goal to which treatment is directed. In the case of normal cells it is a difficulty which has to be faced, and faced very definitely.

Among the problems of purely scientific interest may be placed the development of x -ray analysis. The analysis of crystal structure was the earliest work in this direction, and it continues to yield results of the highest interest in an important field of research. But it may come as news to many that x -ray methods have been extended in recent years to the elucidation of the atomic arrangement of organic compounds and organized structures. Describing as it does the activities of experts in all branches of x -ray and radium work, this report of just over six hundred pages will be found a mine of the most valuable information upon the recent developments and problems raised in radiological science.

MATERNAL MORTALITY

A meeting was held at the Friends Hall, Euston Road, on November 6th, to draw attention to the serious risk which still attends childbirth in this country. The meeting also carried resolutions welcoming any encouragement to local authorities to maintain and develop child welfare services, expressing its uncertainty whether all local authorities were exercising their present powers adequately, urging the Ministry of Health to additional measures, and calling upon local authorities to arrange women's clinics for the supervision of post-natal and associated ailments. The speakers pointed out that the death rate associated with child-bearing remained almost stationary; that approximately four mothers died for every 1,000 babies born alive; and that the puerperal death rate for 1933 was 4.51 as against 3.87 in 1911. The report submitted by the Maternal Mortality Committee analysed the work done by various local authorities, from which it appears that about twenty-nine county councils out of sixty-one are aiding the maternity service in the district by putting into force half or more of the services they have power to provide. Of eighty-four county boroughs about forty-four are doing this, but the position in London is distinctly better, as twenty-two out of twenty-eight metropolitan boroughs appear to be using at least half their powers to aid child-bearing women. The report notices definite progress generally in most parts of the country in spite of financial difficulties and apathy. The committee, however, feels that the time has come for a further advance in the quality and comprehensiveness of the services offered. The most notable advance is the increase in the number of maternity beds, which are manifestly appreciated by the women. The attention of the conference was therefore particularly drawn to the need for improvement in domiciliary midwifery. Proper home conditions include, says the committee, a competent midwife working in co-operation with the

¹ Leipzig: G. Thieme, 1934.

doctor, who has supervised the pregnancy and is prepared to come if emergency arises and to call in a consultant if necessary: they also imply careful maternity nursing, sufficient nourishment, and reasonably comfortable and sanitary surroundings. Medical and nursing supervision should continue until the woman is restored to her normal health. The committee is convinced that after pregnancy there is still much loss of health which is not severe enough to be called "maternal morbidity" in statistics, but nevertheless causes a grave loss of efficiency to the women and to the nation. Overwork, underfeeding, worry, and lack of sleep or rest do not prevent a woman from bearing a healthy child, but the work is done at excessive cost to herself. Despite the satisfactory state of the health of children and young people in the distressed areas, the committee finds a widespread impression that the health of working mothers is showing deterioration, and that they are suffering an undue proportion of minor sickness, anaemia, nervous fatigue, and malnutrition. The disability so caused cannot be measured, but makes it more than ever desirable that the women should be able to obtain advice and assistance not only during pregnancy but also in the intervals of child-bearing. It is within the power of local authorities to set up gynaecological clinics under the Public Health Acts, and the Maternal Mortality Committee suggests that they should be urged to do so as a means of protecting and safeguarding the health of working mothers.

"A DOCTOR FROM PADUA"

An evening reception was held at the Royal Society of Medicine on November 8th at which the customary brief lecture was delivered by Dr. Arturo Castiglioni, professor of the history of medicine at the University of Padua, the subject being the glories of that ancient seat of learning. The large company, which included members of the staff of the Italian Hospital in London, was received by Dr. Robert Hutchison in his president's robe, a copy of that of the rector of Padua. In the library, through the kindness of Dr. Arnold Chaplin, Harveian Librarian to the Royal College of Physicians, some of the treasures of the College were displayed, illustrating particularly the life and work of Linacre, Caius, and Harvey, all of whom had Paduan associations. The authorities of the Wellcome Museum also had loaned some pictures illustrating the subject. Sir StClair Thomson, president of the Section of the History of Medicine, before which Dr. Castiglioni had discoursed the previous evening on Morgagni and the School of Anatomy at Padua, introduced the lecturer and welcomed him in fluent Italian. He reminded those present of the frequent allusions to Padua in Shakespeare; of the remark of Johnson, who had no love for foreigners and their ways, that he had a "mind to visit Padua"; and of the saying of Mandell Creighton that he never visited Germany without realizing how ignorant he was, or France without realizing how stupid, or Italy without realizing how lacking in culture. Dr. Castiglioni then gave a brief historical sketch of his university, referring in the first place to the affinity between the Italian renaissance and the English revival of arts and letters, and in particular

to the bonds between Padua and humanistic Oxford. During the thirteenth century, he said, the prosperity of Padua increased, despite emperors and Popes, and by the fifteenth, in the most brilliant period of Italian history, when the revival of medicine was contemporaneous with the revival of philosophy and art, Padua had already outranked Bologna in renown. At the end of the sixteenth century came the invention of printing, and the foundation of that vast library which now numbered more than 200,000 volumes. He spoke with reverence of some of the great names of Padua, particularly of Vesalius, the most eminent anatomist of the sixteenth century; and showed an old print of Vesalius engaged in dissecting in the famous anatomical theatre lined with carved oak, which was still standing in perfect preservation. In the hall of the university were the coats of arms of its most illustrious students, and among them, on the colonnade of the medical school, the stemma of William Harvey. At one period there was no noble family in England whose coat of arms was not to be found in the collection. The greatest period of Padua was the end of the sixteenth century, when Galileo was professor of mathematics, and students came from all parts of the world—astronomers to study the secrets of the heavens, physicians to explore the mystery of life, and mathematicians to work out their difficult problems. Even in the eighteenth century its international character remained, as seen from the list of professors about Facciolati. A remarkable list of English students who took their degrees at Padua was in existence, though it was sometimes difficult to recognize the English names because they had been latinized, often in a curious form. He mentioned Linacre, who graduated in Padua as M.D.; John Caius, who studied anatomy under Vesalius, and, returning to Cambridge, founded a college which in its by-laws encouraged its students to travel abroad, visiting the fair schools of Padua and Bologna; and William Harvey, whose diploma, in the keeping of the Royal College of Physicians, expressed the warm satisfaction of Padua at his graduation. He recalled John Evelyn's visit, and quoted from Shakespeare's *Taming of the Shrew*:

... the great desire I had
To see fair Padua, nursery of arts.
... I have Pisa left,
And am to Padua come, as he that leaves
A shallow plash, to plunge him in the deep.

But the most generous tribute was by Thomas Linacre himself, who, on bidding farewell to Italy, built a rough altar of stones on the southern side of the Alps, which he dedicated to the land of his studies as *Sancta mater studiorum*. Dr. Hutchison, in expressing the thanks of the company, said that Dr. Castiglioni had sufficiently shown that Padua was the great Mecca of English post-graduates in the sixteenth and seventeenth centuries. They had had many Meccas since: in the eighteenth and early nineteenth centuries, Paris; in the mid-nineteenth, Edinburgh; later, Vienna and German universities; and then the tide set westwards across the Atlantic. But such was the intellectual activity of modern Italy that he would not be surprised if post-graduates from this country in large numbers once again crossed the Alps to visit the cradle of the culture of Europe.

CENTENARY CELEBRATION AT THE OLD BAILEY

One hundred years ago Parliament passed the Central Criminal Court Act, 1834. The Act came into force at the end of July and the first court almost certainly sat on November 1st. The succeeding century has seen such a radical change in the administration of criminal law that the City Fathers felt this year that the completion of the first hundred years of the Central Criminal Court should not pass unnoticed. Accordingly the Lord Chancellor, in the presence of the Acting Lord Mayor and Sheriffs, the City Lands Committee, the Aldermen and Common Councillors, and a large number of members of the Bar practising at the Old Bailey, unveiled a bronze memorial tablet in the upper Hall of the Court, opposite and in harmony with the Court's War Memorial. The name "Old Bailey" is, of course, that of a street which runs from St. Bartholomew's Hospital down towards the river, joining Ludgate Hill about halfway up. There has been a criminal court near the site of the present one from time immemorial. When William the Conqueror came he found the courts of the City of London, including that at Newgate, in such satisfactory working order that he allowed the City to maintain its jurisdiction intact, and in 1132 Henry I issued a charter giving the citizens power to elect their own judges for the Pleas of the Crown. This duty had devolved upon the Lord Mayor, who continually held the commission of gaol delivery and was made a Justice of Gaol Delivery *ex officio* in 1327. Later the administration of criminal justice gradually fell into the hands of professional lawyers, and at the present time the Lord Mayor exercises a nominal function. He is still the principal commissioner of the Court and takes precedence even of the Lord Chancellor, as an acknowledgement of the autonomy of the City; but the work is actually performed by a visiting judge of the King's Bench, the Recorder of London, the Common Serjeant, and a Commissioner. At the time the Act was passed the criminal jurisprudence of London was probably at its lowest ebb. The Old Bailey Court was next door to Newgate Prison, the awful conditions of which, both physical and moral, are now a matter of legend. Prisoners were treated with a brutality which to-day is almost incredible, and children were sentenced to be hanged by the neck for trivial thefts from shop windows. The 1834 Act set the Court on a regular footing and extended its jurisdiction beyond London and Middlesex to Greater London, including offences committed on the high seas or elsewhere within the jurisdiction of the Admiralty. Three years later the scope of capital punishment was much restricted, and thirty years after that execution in public was abolished. As the century passed the whole spirit of the Court rapidly improved. Accused persons were treated with more consideration, and the doctrine that a prisoner is innocent until he is proved guilty passed from theory into everyday fact. Sentences became lighter; the probationary system was introduced with the object of reclaiming offenders; the Poor Persons Defence Act provided for free legal assistance; and prisoners were allowed the right to give evidence on their own behalf. The Court of Criminal Appeal was founded as the final guarantee that as far as was humanly possible no innocent person should be convicted. The bad old days finally passed when Newgate was pulled down and

the present Central Criminal Court was opened by King Edward in 1907. These changes and others were recounted in detail by the Acting Lord Mayor, the Lord Chancellor, the Lord Chief Justice, and the Attorney-General in the addresses they delivered at the unveiling ceremony. The keynote of all the speeches was the part played in these sweeping reforms by the Bar. As Lord Hewart remarked, the changes cannot be put down to mere tendencies or to the spirit of the age. They were mostly the work of individual lawyers, who deserve eternal credit. He singled out particularly Mr. Justice Avory, one of the founders of the Central Criminal Court Bar Mess in 1891, and one of a group including famous names like those of Harry Poland, Travers Humphreys, Percival Clark, Montague Williams, Ballantine, Harding Gifford, and Forrest Fulton. These men led the way in establishing a tradition of respect for the Bench, loyalty to the client, and unswerving rectitude, which has turned the name "Old Bailey" from one of horror and contempt to one which stands for all that is best in criminal justice, and for a system which, though admittedly imperfect in many respects, commands the admiration of the whole world.

BIOLOGICAL PROPERTIES OF ADRENALINE

When considering the biological properties and importance of adrenaline it is generally of its physiological properties that we think. Thus it is common knowledge that its action stimulates that of the sympathetic, and the whole range of functions motivated by adrenaline or adrenaline-like substances, or by the stimulation of the sympathetic, have been classed by Dale under the common head of adrenergic mechanisms in contradistinction to those motivated by choline, choline derivatives, or parasympathetic stimulation. Most of the familiar effects of adrenaline are referable either to vascular phenomena or to biochemical changes. But that adrenaline might have other functions is suggested by a series of experiments carried out during the last few years by A. C. Marie at the Pasteur Institute. The starting-point of these researches was the fact that in many microbial diseases such as diphtheria, tuberculosis, and tetanus, congestion and histological changes are found in the adrenal glands, and the question was considered whether these glands might not exercise some anti-infective function in the defence of the organism. To study this matter by determining the immunity reactions and lethal doses of toxins of the adrenalectomized animal is a method liable to considerable fallacies even if the animal is kept alive by cortical hormone injections, for large amounts of adrenaline are still available in such animals from sources other than the adrenals. Marie, therefore, studied the action of adrenaline on the toxicity of bacterial toxins *in vitro*. Having determined the lethal doses of various toxins when injected into mice, he incubated the toxin with adrenaline and repeated the determination of the lethal dose. It was soon found that the soluble toxins of tetanus and diphtheria as well as the vegetable toxins, abrin, croton, and ricin, could be "neutralized" by adrenaline. In a recent contribution Marie¹ states that adrenaline has no notable

¹ *Ann. de l'Inst. Pasteur*, May, 1934.

neutralizing power against cobra venom, nor does it affect the bacteriolytic power of bacteriophage (*B. shiga*). In contrast to its action on bacterial toxins, adrenaline does not in general affect the growth of the organisms producing the toxins. A peculiar exception is the pneumococcus, a virulent culture of which can be made apparently innocuous to mice by incubation with adrenaline. Even the virulent brain tissue of mice killed with the pneumococcal culture can be rendered avirulent by treatment with adrenaline: no neutralizing effect was, however, found for the brain tissue of rabies-infected animals nor for that of animals killed with the herpetic virus. Another striking effect was that the blood of mice infected with nagana and that of rats infected with *Tr. lewisi* could be made to lose their infectivity by incubation with adrenaline. Marie does not appear to have obtained any explanation of these peculiar findings, and is content as yet to regard them as direct evidence of an anti-infective function of the chromaffin system. Some chemical basis for these results seems certain. It is a peculiar omission that no mention is made by Marie as to whether the characteristic properties of adrenaline are lost as a result of the incubation with toxins, etc. Nor have any data been given to show whether or not the reaction is monomolecular. The work, however, coming from such a source, merits very careful consideration and repetition.

AUSTRALIAN CANCER CONFERENCE

The report of the fifth Australian Cancer Conference, held at Canberra last April, contains a survey of developments in 1933. It includes statistical reviews, papers on cancer research, records of the steps taken in such matters as pathological classification, post-graduate teaching, and radium therapy; and a discussion of various clinical and administrative problems. Reference is made to the expansion of facilities for treatment, in spite of the shortage of beds. Inefficient x-ray apparatus is being replaced by new high-voltage equipment; provision is being made for determination of the quality of the output, and dosimeters installed for measuring in r units. Co-operation between clinician and physicist has become increasingly valuable, and the first steps have been taken towards supplying a definite physical service to treatment institutions. It is noted that there has been an increasing preference for the use of radon for treatment under the conditions governing its issue and use in Melbourne. A new radon plant is being developed at Perth, and more radium has been applied to the production of radon at the University of Adelaide. An improved follow-up system of patients is spreading generally, and a review has been made of 11,760 cases of malignant disease of various regions treated by radium or radon combined with other methods during the five years ended June 30th, 1933. Of 3,071 cases of carcinoma of various regions in an operable stage treated during these five years, 1,918 (62 per cent.) patients are alive and free from symptoms. Diplomas in therapeutic radiology and electricity, and in diagnostic radiology, have been provided at the University of Melbourne, in addition to the existing provision for a diploma in radiology at the University of Sydney.

OXFORD AND THE HISTORY OF SCIENCE

Mr. R. T. Gunther has long been known as the historian of science at Oxford. He has published from time to time a valuable series of reprints of the works of Oxford physiologists who made the University famous in the early years of the Royal Society. He has resuscitated and kept alive the Old Ashmolean, which was in imminent danger of death. He has filled the building with scientific apparatus, much of which was stored, broken and covered with dust, in many a College cupboard. He is now keeper of the Lewis Evans collection of scientific instruments, and holds the newly created office of university reader in the history of science. The inaugural lecture¹ which he delivered in the examination schools on October 25th tells of the difficulties and successes he has met with. He pays a well-merited tribute to the work of Dr. Daubeny, who almost alone stood for science in Oxford when it was a lost cause during the period of the Tractarian Movement. He lays stress upon the value of exhibits in a science museum as a means of education, and urges that pieces of scientific apparatus should not be wantonly destroyed. They should be offered to collections already in being, where they can be properly described, cared for, and preserved. The permanent value of the lecture lies in the fact that Mr. Gunther has added an appendix calling attention to the old scientific books in the various College libraries. This will save the inquirer much time, for he can now go to the particular College where he is most likely to find what he is looking for. It would be well if the list could be enlarged and published separately, for too little is known of the contents of College libraries both at Oxford and at Cambridge.

ROYAL SOCIETY AWARDS

The Copley medal of the Royal Society has been awarded to Professor J. S. Haldane, M.D., in recognition of his discoveries in human physiology and of their application to medicine, mining, diving, and engineering. With the King's approval a Royal medal has been awarded to Professor E. D. Adrian, M.D., for his work on the physiology of nerve and its application to the problem of sensation. The Davy medal is awarded to Mr. W. N. Haworth, D.Sc., director of the department of chemistry in the University of Birmingham, for his researches on the molecular structure of carbohydrates; the Darwin medal to Professor A. C. Seward, Sc.D., Master of Downing, in recognition of his work as a palaeobotanist; and the Hughes medal to Professor K. M. G. Siegbahn for his work on long-wave x rays. Sir Frederick Gowland Hopkins has been nominated for re-election as President of the Royal Society, and Sir Henry Dale as joint secretary. The names of Professor Adrian, Professor T. R. Elliott, Dr. P. P. Laidlaw, and Sir Charles Martin have been put forward for election as members of council for the ensuing year at the annual general meeting on St. Andrew's Day, November 30th.

As we go to press we regret to announce the sudden death of Dr. Vincent M. Coates of Bath.

OPENING OF SAMARITAN FREE HOSPITAL EXTENSION

An extension of the Samaritan Free Hospital in Marylebone Road, London—the hospital always to be associated with the name of Spencer Wells—was opened by Lord Moynihan on November 13th. H.R.H. Princess Arthur of Connaught, the president of the hospital, was present, together with the mayor of St. Marylebone (Alderman John Fettes) and a distinguished company. The extension comprises a general ward, together with fourteen single-bedded private wards and twenty-four nurses' bedrooms; it has cost £27,000, of which about £5,000 has still to be raised. It is also proposed to provide a deep x-ray therapy department, and as soon as the further £5,000 necessary for this purpose is forthcoming King Edward's Hospital Fund will be asked for permission to put an additional story on the new building to provide the accommodation.

Dr. A. W. OXFORD, who presided over the opening ceremony, said that he first became acquainted with the hospital in 1878, when he was a young curate, and one of his old parishioners in a slum district was admitted for a very large ovarian tumour. Her complaint, when he visited her, was that the night nurse always drank her brandy, and indeed in those far-off days of hospital administration such complaints were not without some basis. One matron more than half a century ago charged her grapes and peaches as "cabbages for the patients." He never forgot the horrified expression of some members of the committee when it was discovered that this matron, while she was supposed to be on duty, had gone to the Oaks. But that chapter was long since ended. The hospital had a great reputation for pioneer work in abdominal surgery, and he always remembered Sir Frederick Treves saying, when he opened the operating theatre in 1907, that at the London Hospital every surgeon asked what the Samaritan was doing, so great was its renown in its particular field. Only two or three years ago Sir George Newman or one of his colleagues at the Ministry had stated that in the special work which that hospital did it had far greater success than any other hospital in London.

ADDRESS BY LORD MOYNIHAN

Lord Moynihan, in declaring the extension open, said that he had a special reason for pride, because it was in that hospital that Spencer Wells, a student of the Leeds School of Medicine, and for a time articulated to a practitioner in North Street, and afterwards to Dr. Sadler of Barnsley, began those intrepid and immortal enterprises that changed the face of surgery, giving it a new orientation, a new territory, a new incentive. Not the least remarkable achievement of Spencer Wells was to have accomplished so much before the advent of Lister; indeed, he declared that the introduction of the antiseptic method made little difference to his results. The explanation was, doubtless, that Spencer Wells was a "dandy," fastidious about the cleanliness of his hands and the purity of his linen, and himself scrubbing his instruments after every operation. It was in the Samaritan that Spencer Wells's first triumphs were won. He did more than relieve the individual patient: he converted surgery from a merely remedial art to a great scientific instrument for research. It was the mark of a great surgeon to turn mistakes to good account, and some of Spencer Wells's mistakes became landmarks in surgical history. When operating for a supposed ovarian cyst he had found no tumour but an ascites due to tuberculous peritonitis. His operation cured the patient and inaugurated the surgical treatment of abdominal tuberculosis. In 1887, when operating upon a girl, jaundiced since birth, for what was thought to be a fibroid tumour of the uterus, he found that the tumour was not pelvic in origin but splenic; he removed the spleen, and the girl recovered, and so began the surgical treatment of haemolytic jaundice. It was a direct result

of Spencer Wells's inspiration and teaching that surgeons had been enabled to rewrite, with greater accuracy and with incomparable authority, the clinical truths of visceral medicine.

One further point deserved remembrance. Spencer Wells was a general surgeon who helped to create a specialty. It behoved them all to recognize that specialties would only flourish so long as they remained attached to the main stem of medicine. A gynaecologist, for example, must be trained as a general surgeon, and must remain competent to deal with all conditions he might unexpectedly encounter. In the old days Lord Moynihan remembered being summoned from his own operation theatre to a neighbouring one to deal with a carcinoma of the sigmoid flexure, or a condition of diverticulitis which had suffered erroneous diagnosis. So, too, the gynaecologist should not only be competent to deal with all conditions in his own special territory, but should be able—and always inclined—to remove an appendix or to empty or to remove a calculus-containing gall-bladder. Though the development of specialism was inevitable and highly necessary, regard should always be paid to the Hippocratic ideal of the unity of medicine.

"When I read in the recent report of the Chief Medical Officer to the Ministry of Health that out of a total of 2,618 maternal deaths in 1933 no fewer than 1,016 were due to puerperal sepsis, it seemed obvious that it would be all to the advantage of parturient women that the act of delivery should be surrounded with all the stern but simple ritual of a surgical operation of the first magnitude. It must constantly and conscientiously be borne in the very forefront of our minds that no small proportion of the morbid conditions seen in the gynaecological wards to-day are preventable. In this country vast sums of money are annually expended upon the care of those who, for physical or mental reasons, are never likely to be useful members of the community or to be of service to the State. The time is long overdue when consideration should be given to the culture of the physical condition of the normal youth and child. If this were done the normal girl would be better able to bear the strains and perils of maternity. If also a far sterner training in the technique of antiseptic methods were more strongly insisted upon in the training of obstetric nurses, not only would maternity become safer, but a grievous and unjust burden would be lifted from such hospitals as this."

DEDICATION BY THE BISHOP OF WORCESTER

After Lord Moynihan's speech the new extension was dedicated by the BISHOP OF WORCESTER, and then Lord MANNERS, treasurer of the hospital, proposed a vote of thanks to Lord Moynihan, which was seconded and supported by Captain CUNNINGHAM-REID, M.P., Mr. CLIFFORD WHITE, the senior surgeon, and the MAYOR OF ST. MARYLEBONE. Captain Cunningham-Reid and the Mayor both expressed the appreciation of the borough and its pride in including such hospitals as the Middlesex at the one end and the Samaritan at the other, with Harley Street in between.

Lord Moynihan, in reply, said that he was rather pained to note the small amount for which this hospital was asking—a trifle of £5,000 or £10,000. Could not something bigger be achieved? There was not a woman in this or in any other civilized country who did not owe a debt to the work which had been done at the Samaritan. Was it out of the question to inaugurate a great national women's fund on its behalf? Could they not fly their flag a little higher? Instead of a paltry £5,000, let them ask for half a million, and make the hospital what it ought to be—the greatest women's hospital in the world. It was a hospital with traditions, but traditions were kept alive, not by the observance of ancient ceremony or mute obedience to outworn creeds; they were kept alive by an active faith, for ever seeking new truths and exploring new paths in conformity with the old spirit. "You have one of the great shrines of surgery here. Let the world know of it, and let every woman here be an ambassador of this hospital of incomparable fame. Ambrose Paré said: 'It is beautiful and the best of all things, to labour for the relief of human suffering.' Such words as those I would see upon the banners of the women who go out as missionaries of this hospital."

SOUTH AFRICAN MEDICAL CONGRESS

[From our Correspondent in Pretoria]

The Annual Congress of the Medical Association of South Africa (B.M.A.) was held in Pretoria during the week commencing October 1st under the chairmanship of Sir Edward Thornton, Secretary for Public Health and Chief Health Officer for the Union. This is the twenty-eighth medical congress held locally, and the seventh since the profession in South Africa became united into a single association, of which the great bulk of local practitioners are members. Pretoria was in spring garb, and the 240 delegates who attended saw her nearly at her best; it required another month, however, for her jacaranda-lined streets to be draped in deep blue.

After the induction of the President by Mr. T. Lindsay Sandes, President of the Federal Council of the Medical Association of South Africa (B.M.A.), the visiting members were welcomed by Dr. H. A. Hahn, President of the Northern Transvaal Branch, and by Mr. Ivan Solomon, Mayor of Pretoria, on behalf of the city. Referring to life as that long-drawn-out fight for time, Mr. Solomon said that those who controlled, supervised, and reinforced that fight were among the most important people in the world. As regarded that other section of the community, the patients, he assured Congress that they appreciated to the full the great part the doctors played in the life of the nation. He hoped that in the administrative capital of the Union delegates would find that atmosphere of unhurried stability and gracious dignity which was the special charm of the city.

A NATIONAL HEALTH INSURANCE SCHEME

The Congress was then formally opened by the Minister of Public Health, the Honourable J. H. Hofmeyr. In his address he foreshadowed the possibility of special legislation in South Africa prohibiting the publication of advertisements for quack medical products. The law, he said, sought to eliminate the quack practitioner, and, to a limited extent, it purported to deal with advertisement of remedies which claimed to achieve what was manifestly impossible. But the law was incomplete in both respects, markedly so in regard to the quack advertisement. He invited the advice of the medical profession on this matter, and also the approval of the Association for the steps he proposed to take in connexion with a scheme of national health insurance. Such a scheme was within measurable distance; it was, indeed, the only form in which a State medical service was within the range of practical politics in South Africa. One of the prerequisites of its institution was the working out of a detailed basis of co-operation between the State and the medical profession. He was considering the advisability of appointing an *ad hoc* committee on which the profession would be adequately represented. He wished especially to bespeak the sympathetic interest of the Association in the Government's scheme for a Native Health Service, whereby it was seeking to remove a grave reproach at present resting on South Africa. A course of training for native medical aids was being instituted at the South African Native College at Fort Hare. He was glad that the Federal Council of the Association had expressed its approval of the scheme in principle, and he hoped that the profession would help the Government to work it out in detail.

THE PRESIDENTIAL ADDRESS

Sir Edward Thornton chose as the subject of his address some of the problems in the sphere of preventive medicine. He said that the application of the science of preventive medicine involved in South Africa a number of agencies. The first of these was a Minister, who, subject to the regulations, and controlled expenditure. The country had been fortunate in the four Ministers who had held the portfolio since Union. Each in turn had done all that was possible within the limits of the moneys available to

promote the public health. Next came the Department of Public Health, which served as a central co-ordinating body supervising the operations of State medicine initiated by the Minister and Parliament. The provincial administrations again were responsible for general hospitals, the relief of the poor and needy, the medical inspection of school children, and the control of local government, including schemes of sewerage and water supply and sanitary regulations. The division of responsibilities for health matters as between the central and provincial Governments was responsible largely for the fact that advance in public health matters had hitherto been retarded. These responsibilities required to be more clearly defined before any further advance on a large scale was possible.

The real unit of public health control was the local authority. In the case of the large towns, with a few exceptions, that control was reasonably satisfactory, but in the smaller towns and villages, with a few notable exceptions, the control was generally unsatisfactory. This was mainly due to the fact that the protection of health involved some local expenditure. It would have been very much easier to have as the administrative unit for public health control outside the large towns something in the nature of large county councils able to employ and to pay for proper health staffs. He wondered whether it was still too late to bring such a project to fruition in South Africa. If the advance in public health which was so urgently required and which was being so insistently demanded by the public and by the Medical Association was to be assured, if the fight against tuberculosis was to be properly undertaken on a national basis, if the prevention and control of venereal disease were to be organized so as to give lasting results, and if the present excessively high maternal and infant mortality rates were to be materially reduced, it was essential that provision should be made for larger and financially stronger units of local health administration than were available outside the few large towns to-day.

National health itself could not be obtained unless and until the people demanded it. It certainly could not be secured, still less imposed, by Parliament, the Minister or his Department, the Provincial Administrations, or even by local authorities. Health could only be achieved by the people themselves when they understood the necessity for it. The nation did not yet understand the necessity of practising the rules of health, and this Sir Edward attributed to defects in the country's educational systems which provided qualified teachers with little or no knowledge of the laws of health. The future health of the nation depended far less upon housing or medical services than it did upon an educated people. Teachers required a good working knowledge of the facts of growth and functioning of the whole human body; they should be taught the essentials of biology, physiology, and the factors associated with personal hygiene, and they should be taught how to hand on this information to children.

Lastly, the medical, dental, and nursing professions were the spearheads in the advance to victory in the health campaign. This they could only be if the spears were in line and turned in the right direction. He believed that the right direction in South Africa was towards the rural areas, which had been deplorably neglected in the past. The State's duty was to ensure that the inhabitants of the rural areas of South Africa, black and white, were able at least to secure at a reasonably cheap rate adequate medical and nursing services. In regard to native areas, the provision of trained medical and nursing aids working under an extended district surgeon system and under the various mission stations appeared to be the only practicable means of bringing relief to the people. In conclusion, Sir Edward said he hoped that during his term of office as Secretary for Public Health it might be his good fortune to see some of the disabilities under which the profession laboured removed or adjusted, so that there might be established the most harmonious relations possible between the various Departments of State and local government served by the profession and the organized profession itself, for without the assistance of the latter no real progress in public health was possible.

PLENARY SESSIONS

There were three plenary sessions, at which subjects of general interest were discussed by Congress as a whole. On Monday morning the subject of anaemia was presented as a symposium by members of the medical and veterinary professions. Owing to the existence just outside Pretoria of the large and internationally famous Onderstepoort Veterinary Laboratories, it had been decided to invite the professional officers of this institution to honorary membership of Congress. This gesture was abundantly justified, and the twelve veterinary members proved a valuable asset. The symposium on anaemia was provided by Dr. G. Buchanan of the South African Institute for Medical Research, Johannesburg, and Dr. Gilles de Kock, Deputy Director of Veterinary Services for the Union, the discussion being opened with papers by Dr. L. I. Braun of Johannesburg and Dr. P. Fourie of Onderstepoort.

On Tuesday morning the plenary gathering discussed surgical conditions of the liver, including the gall-bladder; the subject was introduced by Mr. I. W. Brebner, professor of surgery at the University of the Witwatersrand, and the opener of the discussion was Dr. W. J. May of Durban. On Thursday morning the subject for general discussion was infant feeding, introduced by Dr. S. C. Heymann, the opener being Dr. B. G. Melle; both of these members practise paediatrics in Johannesburg.

THE SECTIONS

Congress was divided into the same five Sections as at previous meetings: (1) medicine; (2) surgery; (3) gynaecology and obstetrics; (4) public health; and (5) special subjects. Under the last of these a very useful subsection on comparative medicine was added, papers being contributed by three veterinary officers from Onderstepoort. The value of their papers to a medical gathering was evident from the titles—for example, the paper by Dr. G. Steyn on poisonous plants associated with bread poisoning. In this subsection there were two contributions of great local interest, one by Dr. A. Pijper, on typhus-like diseases in South Africa, and another, jointly by Drs. F. W. Fox and L. F. Levy of the South African Institute for Medical Research, on the antiscorbutic value of some South African foodstuffs. The latter was of particular interest, since it followed on a recommendation made last year by the Capetown Congress that the Government should be approached with a view to instituting an inquiry into South African food substances. The Institute for Medical Research subsequently undertook such an inquiry, and this paper by two of its officers represents the first-fruits of its labours.

The contributions in the other Sections offered the usual varied fare, almost every branch of medicine, surgery, and obstetrics being touched on. In the Public Health Section the papers gave a reflex of the trend of public opinion in South Africa on health matters. Professor T. Shaddick Evans, medical officer of health of Capetown, read a paper, which was subsequently discussed at great length, on the housing problem, with special reference to the Slums Act. Dr. S. Annecke's contribution was on malaria control in the Transvaal, and Dr. Melle's on ten years' experience in the infant welfare centres in Johannesburg. In the Subsection of Radiology and Physiotherapy Dr. F. H. Domisse of Capetown read a paper on the dangers of x rays and radio-active bodies, and the methods of protection against them. The grave dangers to workers and the public if such bodies are uncontrolled in South Africa had recently been given prominence, and the Congress Committee had specially asked for a discussion of this subject.

SCIENTIFIC AND TRADES EXHIBITION

The Scientific and Trades Exhibition was opened on Monday morning by the President. Thirteen firms had taken stands: Allen and Hanburys (Africa) Limited; Leannon Limited; South African General Electric Company; Smith and Nephew (Pty.), Limited; B. Owen Jones, Limited; Surgical Instrument Company, Limited; Sive Bros. and Karnovsky, Limited; Westdene Pharmacy; Keating's Pharmacy; Menley and James

(Colonial), Limited; Tacuber and Corssen (Pty.), Limited; Schering-Kahlbaum S.A. (Pty.), Limited; and Fassett and Johnson, Limited. This exhibition is worthy of more support by delegates than is usually given at Congresses, because on the fees charged to the various firms depends very largely the financial success of the Congress as a whole.

ENTERTAINMENTS

Plenty of entertainment was as usual provided for visiting delegates and their wives. On Monday, after the official opening, the President's Reception took place at Berea Hall. Visits were provided on the other afternoons to various places of interest, such as the Government Steel Works, the Onderstepoort Laboratory, the Royal Mint, and the Police Depot, where detective dogs are trained. Even lighter fare was provided by a night at the theatre, at the end of which delegates were sustained by tea and cakes, and a night at the Greyhound Racing Ground. On Wednesday afternoon the Administrator of the Transvaal held a garden party at Burgers Park, and on Wednesday night the Mayor of Pretoria gave a Civic Ball. Congress closed with a very successful, at times hilarious, dinner at the Pretoria Club on Friday night.

India

Medical Aid by Women for Indian Women

In 1935 the original Countess of Dufferin's Fund will celebrate its jubilee; it will also be the twenty-fifth year of the Queen's patronage. Known otherwise as the National Association for Supplying Medical Aid by Women to the Women of India, which incorporates also the Women's Medical Service, it has played a noble part in improving the lives of Indian women by carrying the potentialities of modern medicine behind the hitherto rigid veil of the purdah. The report of this organization for 1933 points out that, although in many places purdah has been broken, and women can now call upon the services of medical men, there are still millions of Indian women living in strict purdah, and many more women doctors are needed. There is also the work of preventive medicine, the building up of a new generation of healthy children in the great new India which is foreshadowed. The waste of maternal and infant life continues, as also much unnecessary suffering and invalidism of women, with many a child born only to become blind or crippled. So the work of the Dufferin Fund is far from finished; indeed, further immediate advance is urgently required. In 1933 the Government's grant could not be paid in full, as was the case also in the previous year, necessitating the continuance of a cut in the salaries of those employed by the Fund, though to a less extent. The earthquake havoc in Bihar and Orissa will still further handicap the financial capability of a Province which has already had to default as regards its usual contribution towards the salary of the Women's Medical Service officer at Gaya, as well as rendering the local needs more urgent. The present report contains, as usual, interesting details about the progress made in various hospitals, training, and other activities of the National Association. The wards of the Lady Hardinge Medical College Hospital at New Delhi have been over-full, and the steady increase of gynaecological and midwifery patients has compelled separation of the two units. This will be made possible by converting at a nominal cost part of the out-patients' block, which at present is not in use, into an isolation ward for septic and infectious cases. By this reorganization a large ward with its side rooms will be freed for septic gynaecological cases, leaving the present gynaecological ward for maternity cases. The amount of radium in this institution has been increased so as to bring it up to the requisite optimum dose for a case of uterine cancer. There has been a marked increase in the number of patients

who have been treated successfully with electrotherapy of different kinds. The training departments for nurses and compounders have made satisfactory progress. The Dufferin Hospital at Karachi was in a rather dilapidated condition, and much work on it still remains to be done when funds permit. In the year under review the out-patients' department was rebuilt, but it is necessary to raise the level of the whole compound to that of the roads outside. The two operating theatres have received better equipment, but there is still needed a galvanocautery and diathermy apparatus, as well as an ultra-violet ray lamp. A septic midwifery block is being constructed, but the present obstetric block urgently needs extension, for there is almost constant congestion in the general wards, and accommodation is lacking for ante-natal or waiting patients, and for such conditions as threatened eclampsia, albuminuria, and osteomalacia. A diploma course in maternity and child welfare has been started in the All-India Institute of Hygiene in Calcutta. The ante-natal clinic at the Dufferin Hospital in this city affords abundant material and excellent teaching, but individual instruction has been hampered by the large number of patients and the limited accommodation in the out-patients' department. There are good facilities for post-graduate experience in advanced midwifery at the Eden Hospital, so far as lectures and bedside clinics are concerned, and practice in the administration of anaesthetics is adequate, but the opportunity for the actual performance of obstetric manipulations is very limited. It is pointed out in the report that practice in midwifery is a most important part of the training. The Eden Hospital is a most suitable place in which to gain experience, and it will be very unfortunate if the necessary changes cannot be made to bring the post-graduate practical work up to a reasonable standard. Lectures and demonstrations in general hygiene, public health chemistry, ante-natal care, and the organization of midwifery services have been proceeding at the All-India Institute of Hygiene and Public Health. The foregoing illustrates some sides of the widespread work of the great scheme that has grown out of the Countess of Dufferin's original fund. Small as well as large hospitals and dispensaries are slowly multiplying in areas where they are most required, and achieve swift popularity as the benefits of modern scientific medicine are realized by the women in backward communities. Despite financial handicaps and occasional local setbacks the work goes on.

Medical Services in Mysore

According to the Government report just issued medical services have shown a considerable expansion in Mysore during the past year. The opening of two new dispensaries brings the number of State medical institutions up to 280. The construction of a new building for the Yam Valas Hospital, and a radiology block at the Victoria Hospital, both in Bangalore, are other important pieces of work, as well as the construction of the Sri Rukminamma Maternity Hospital at Chikmagalur, a new hospital at Ghimoga, and the addition of maternity and children's wards and ophthalmic blocks to leading hospitals throughout the State. The total number of attendances in the various institutions increased from 3,851,000 to 4,231,000. This does not imply an increase of disease, but rather that the population, in the past doubtful of the value of Western medicine or outside its reach, are now making full use of the new facilities provided. The volume of work in the electrotherapeutic and pathological departments in Bangalore and Mysore also showed a very large increase. Total expenditure has risen to the equivalent of £1,053,000, mainly as the result of larger staffs, as well as medicines and diets needed for the increased number of patients.

Ireland

Medical Treatment of School Children

At a recent meeting of the Clogher Regional Committee a letter from the Ministry was read in which it was stated that the education authority was responsible for providing free medical treatment where absolutely necessary, but that it was generally expected the parents or guardians would bear the cost of such treatment. The secretary remarked that the committee had been complying with the Ministry's regulations in this matter, but it was resolved that all applications for medical treatment should come before the subcommittee of the district in which the applicant resided, and that the nurse should see that the small sum of 2s. 6d. was contributed in every case. While the regional committee mentioned the minimum of 2s. 6d., it was expected that in most cases the parents would meet the full amount.

Anaemia: Yesterday and To-day

Dr. Francis J. O'Donnell read a paper entitled "Anaemia; Yesterday and To-day," at the inaugural meeting of the Biological Society of the Royal College of Physicians and Royal College of Surgeons, which was held in the Examination Hall of the latter body in St. Stephen's Green, Dublin. Dr. O'Donnell stated that in any case of serious anaemia accurate diagnosis and proper treatment and after-care demanded considerable and constant laboratory investigation. These requirements presented in concrete form—but only in one section of medicine—problems of medical service to the community at large and of hospital organization upon which it would be wise for the medical profession in this country to come to specific decisions within the next few years. As concerned hospital work on anaemia, the necessary laboratory investigations required the services of a reasonably well-paid or whole-time pathologist, since no member of a staff could be expected to undertake such a time-consuming work and make his livelihood afterwards. To utilize to the full these paid services a large hospital was essential, and it was apposite to point out that in several British teaching hospitals not merely whole-time pathologists but whole-time *directors* of the various units had now existed for some years past. The treatment of anaemia illustrated very aptly the problem raised by the rather crisp assertion that under existing conditions two sections of the community could secure proper medical care and treatment—the wealthy, who paid for them, and those who could get them for nothing in a hospital. That generalization remained substantially correct, because the kernel of the problem was not the part-extension of gratuitous medical service, but rather the necessity of placing adequate facilities for proper diagnosis and treatment at the disposal of people with moderate incomes, who were willing to pay for such facilities within the limit of their incomes and social responsibilities. The difficulties of such a question were obvious, but its importance in a country where the middle classes had increased enormously could not be denied. In Great Britain some efforts had been made to meet that need by means of voluntary insurance, a solution with at least considerable possibilities if sufficiently supported. In the same connexion the general practitioner had to be considered. It would be agreed that any system of medical education worthy of the name aimed at producing a doctor alive to the first warnings of disease, and the logical corollary was that the general practitioner should be afforded the assistance of all modern advances in direct relation to all classes of his patients. Proposing a vote of thanks to Dr. O'Donnell, Dr. T. G. Moorhead, Past-President of the

British Medical Association, referred to the time when the extraction of teeth was considered to be a cure for anaemia. Archaeologists of the future, he said, would think that at that period there had been a sudden disappearance of teeth. He was particularly interested to observe that Dr. O'Donnell had referred to the necessity for adequate after-care, and that brought them once again to the importance of establishing in connexion with every hospital a social service unit. He hoped that in a comparatively short time he would have established such a unit in his own hospital. Again and again he had pointed out that hospitals were dealing only with sickness, and were taking no part in its prevention.

England and Wales

Liverpool School of Tropical Medicine

At a special reception at the Liverpool School of Tropical Medicine, on November 6th, the Mary Kingsley medal was presented to Dr. Henry Beeuwkes, Sir George Buchanan, Colonel Sir Rickard Christophers, and Sir Malcolm Watson. Honorary recipients were Miss A. P. Caton and Mrs. Middlemass Hunt. The Duke of York, who is president of the School, sent congratulations to the recipients, and expressed warm wishes for the future success and prosperity of the institution.

Lord Leverhulme, chairman of the School, said that the munificence of Liverpool citizens had brought it into being originally, and that the School had amply repaid the debt by adding lustre to the name of the city in the eyes of the world. Liverpool, he hoped, would continue to lead in tropical medicine, not necessarily in the size of its buildings, but in the importance of the discoveries which it made. In the past the School had rendered it possible for 40,000 persons to live and work in the region of the Panama Canal, where once 90,000 had perished. From its foundation in 1898 until 1914 it had dispatched thirty-two expeditions to West Africa and other tropical areas. At the present time, in its laboratory at Sierra Leone, it continued to deal with the everyday problems of tropical diseases, and by patient research was extending knowledge how to conquer them. The Mary Kingsley medal had been instituted in 1904 to commemorate the services of the niece of Charles Kingsley, the novelist, to the welfare of the West African native. The qualifications for it were service in the prevention and fighting of disease in the Tropics. Professor Warrington Yorke described the contributions made by the six recipients. In the person of Mrs. Middlemass Hunt, he said, the School was publicly acknowledging the services rendered by her late husband, Dr. John Middlemass Hunt, its honorary dean from 1921 until 1932, who had endowed the chair of tropical diseases of Africa. This chair was occupied by the director of the School's research laboratory in Sierra Leone, where members of the staff could gain first-hand experience by working in the actual climatic conditions of an unhealthy part of the Tropics. It had been realized that lack of adequate endowment was likely to endanger the existence of this laboratory. Dr. Middlemass Hunt, by his far-sighted generosity, had taken the first great step towards its proper endowment, and the resulting professorship would constitute a permanent and conspicuous landmark in the development of the School. Miss Caton's father, the late Dr. Richard Caton, had taken a prominent part in the foundation of University College, and in 1902 was appointed to represent the council of the College on the governing body of the School. In 1913 he was elected its vice-chairman, and held this post until his death in 1926. Miss Caton's generosity subsequently had enabled a research fellowship to be founded. She had taken a

prominent part in promoting the welfare of people inhabiting tropical countries—particularly India, where she was at present honorary secretary of the Village Welfare Association. Dr. Henry Beeuwkes, a graduate of Johns Hopkins University, after distinguished work in connexion with the Armenian Relief Mission and child welfare in the United States, had studied yellow fever in Brazil and Central America, and had organized and directed the Yellow Fever Commission in West Africa. He had subsequently conducted researches which had ultimately incriminated the *Stegomyia* and other mosquitos as carriers of the ultra-microscopic causative virus, and had elaborated a protective serum. Outstanding features of the work of Sir George Buchanan were his great administrative abilities at home and in conjunction with the Health Organization of the League of Nations. Many far-reaching international agreements, such as the Brussels Convention, had been largely due to his negotiations. Most important of these was the International Sanitary Convention of 1926, which had recast and modernized the whole international system of preventing the spread of small-pox, typhus, cholera, plague, and yellow fever, while the International Sanitary Convention for Aerial Navigation of 1932 had intensified the control of yellow fever and the prevention of its spread, especially to the East. He was still prominent in his double capacity of president of the International Office of Public Health in Paris and vice-president of the Health Committee of the League of Nations. Sir Rickard Christophers, a Liverpool graduate in medicine, had been a member of the classical Malaria Commission of the Royal Society and Colonial Office. With Professor Stephens he had been the first to establish the malarial nature of blackwater fever, and he had given valuable services with regard to increasing knowledge about the great epidemics of India, the transmission of *Protoplasma* through the tick, and the practical study of malaria generally. Sir Malcolm Watson's antimalarial work since Ross's great discoveries had introduced a large variety of preventive measures, and had saved innumerable lives since 1901. He had devised and introduced the valuable subsoil drainage system, and was largely responsible for its present widespread utilization in Malaya. In connexion with the Ross Institute, of which he was director, he had made numerous and most fruitful contributions to the knowledge of malaria and of its pathological effects.

Tuberculosis in Birmingham

Dr. G. B. Dixon, chief clinical tuberculosis officer to the City of Birmingham, reports a decrease in the number of notified cases of all forms of this disease in 1933, the case rate per 1,000 of the population (1.45) being the lowest yet recorded. Statistics are supplied which show that the mortality rate has been falling steadily since 1901, and the present five-year period (1931-5) seems likely to establish a new low record for quinquennial periods. This decrease affects both pulmonary and non-pulmonary forms. Birmingham's case rate of 1.4 per 1,000 compares favourably with other great centres of population, and notably with Liverpool (3.3), Sheffield (3.2), Glasgow (2.1), Manchester (1.8), and Edinburgh and London (1.7). At the end of 1933 there were 7,180 cases of tuberculosis on the current register. Ten nurses are engaged as visitors, and a total of over 30,300 visits were paid in the twelve months. It was discovered that 771 patients out of 1,640 were sharing a bed with some other person, while 592 shared a bedroom, but had a separate bed. Efforts are always made to get a separate bedroom, or at any rate a separate bed, for each patient, but it is noted that lack of accommodation or unwillingness of patients often renders this impossible. In order to promote segregation, ninety-seven persons received bedding from the department on loan or hire purchase, while, in addition, twenty

chalets were sent out to patients who were in a position to use them. There were 5,180 consultations with medical practitioners during the year, and the number of reports received from them in the same period was 1,814. It is noted that 22.6 per cent. of adults were notified in the first instance while their working capacity was unimpaired, whereas 35.9 per cent. only came when totally incapacitated for work. The statistical table devoted to family histories brings out the interesting point that the father is known to have been a sufferer from tuberculosis more frequently than the mother. The large increase in the number of patients attending at the tuberculosis centre in the city is accounted for by the fact that the patients receiving light treatment have been recorded for the first time this year. Of the patients treated during the period 1913 to 1933 about 11,000 had tubercle bacilli in the sputum; of these, 26.9 per cent. are still alive, 65 per cent. have died, and the condition is unknown in about 8 per cent. During the same period over 12,000 patients whose sputum contained no tubercle bacilli were treated; of these, 63.5 per cent. are still alive, 19.6 have died, while trace has been lost of the remainder. In all of the municipal sanatoria occupational therapy is prominent, while a scheme for encouraging after-care employment has proved clinically as well as economically successful.

Scotland

Hospital Services for Scotland

In an address to the Edinburgh Women Citizens' Association Dr. R. W. Craig, Scottish Medical Secretary of the British Medical Association, criticized present-day medical services and outlined the features which were desirable in the future. He said that some thirty years ago poverty had been one of the chief claims for admission to hospital, but to-day the gravity or danger of the illness or injury was the criterion for admission. In 1871 the Glasgow Royal Infirmary, which was then the only voluntary general hospital in Glasgow, admitted 2,225 medical cases and 2,421 surgical ones. Thirty years later, in 1901, there were three large voluntary hospitals in the city, and the number of surgical cases had increased to 9,000. In 1924 the medical cases had increased only to 6,000, while the surgical patients numbered 21,000. This development naturally gave rise to new problems in connexion with the accommodation in hospitals. The Departmental Committee on Hospital Services, under the chairmanship of Lord MacKenzie, had recommended that hospital treatment should be entirely dissociated from the Poor Law, and effect had been given to this in the Local Government (Scotland) Act of 1929. The voluntary hospitals had done splendid work for the country, and it was remarkable that, faced as they had recently been with the steadily increasing demands upon their facilities, they had been able to maintain their functions at a high level of efficiency. That had been possible because the community realized that such essential services must be subsidised at all costs. People who had given serious consideration to the hospital problem felt that the continuance of the voluntary system was in the public interest. It was evident that hospitals would be affected by any development which took place in the general medical service of the country. It was safe to say that in the near future there would be a considerable increase in the provision of organized medical services for great sections of the community. At present there was a superfluity in one direction and a deficiency in another, with very little co-ordination between certain branches. In the sphere of family practice there was overlapping, which was wasteful and sometimes chaotic; it had often

been found that in the same family medical care was being provided from ante-natal clinics, child welfare clinics, the school medical service, the public assistance service, hospitals, and the general practitioner. The British Medical Association strongly believed that the large expenditure of funds involved in these services could be more usefully employed if it were diverted to the provision of medical attention by a system based on the family as a unit instead of by a system which regarded the family as a loose arrangement of unrelated components. If a general and complete medical service were readily available to all members of the family it would lessen the need for hospital beds, since more cases could be treated at home than at present, and existing beds would be more efficiently used. It would also increase the efficiency of the family doctor if opportunities were afforded him in hospital for the treatment of those of his patients who did not require more than general practitioner treatment, while at the same time the services of specialists would be immediately available. The British Medical Association was of the opinion that an arrangement of this nature in every area would be of great value; it would not necessarily require the establishment of new hospitals, for the provision might be made by setting aside a number of beds in existing institutions.

Central Midwives Board for Scotland

The examinations of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, have just concluded with the following results. Out of 170 candidates who appeared for the examination 155 passed. Of the successful ones twenty-nine were trained at the Royal Maternity Hospital and eighteen at the Elsie Inglis Memorial Hospital, Edinburgh; forty-six at the Royal Maternity Hospital, Glasgow; eleven at Stobhill General Hospital; two at the Eastern District Hospital; two at the Western District Hospital; seven at Govan Maternity Hospital; nine at Bellshill Maternity Hospital; four at Barshaw Maternity Hospital, Paisley; one at Motherwell Maternity Hospital; seven at the Maternity Hospital, Aberdeen; fourteen at the Maternity Department, Royal Infirmary, Dundee; two at the Maternity Department, Royal Infirmary, Perth; and three at the Royal Infirmary, Stirling.

Reports of Societies

"SOME PERSONAL PREJUDICES"

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on October 12th, with Sir WILLIAM SMYLY in the chair, the president of the Section, Dr. T. M. HEALY, read as his presidential address a paper entitled "Some Personal Prejudices."

Dr. Healy gave an analysis of the 13,347 intern and extern maternity cases occurring in the first five years of his mastership of the Coombe Hospital. The intern morbidity rate—the B.M.A. standard—for the period was 3.6 per cent., and the case mortality rate in puerperal sepsis was 10 per cent. He gave figures showing that operative cases ran a risk of sepsis five times greater than that of cases delivered spontaneously, yet the case mortality from sepsis was only 1.5 per cent. higher in operative deliveries. He was in favour of induction of premature labour as a method of preventing difficulty from disproportion, and attributed the fact that he was unable to show a decrease in his incidence of Caesarean section to the reluctance of the patients to enter hospital sufficiently early in pregnancy.

Sir WILLIAM SMYLY said that he still believed that "meddlesome midwifery" was bad. It was difficult to compare results obtained in an intern and extern department, because the bad cases were generally sent in to

the hospital, so internal statistics were bound to be worse than those of an extern department. He would like to see added to the induction column in the statistics shown by Dr. Healy the number of babies which were born alive but died before they left hospital. He thought that one of the disadvantages of induction was that premature babies were more likely to die within a few weeks of birth than babies who were not premature.

The MASTER OF THE ROTUNDA said that at his hospital he had tried as far as possible to accomplish vaginal in preference to abdominal delivery. He felt that ante-natal care had now gone almost too far, and statistics showed that it had led to increased operative midwifery, which he felt was a thing to be avoided. He had no doubt that the increase in induction of labour had definitely led to an increase in the performance of Caesarean section. Induction of labour by puncture of the membranes was both a blessing and a curse. It was a curse when one attempted to bring a borderline case into labour. He thought the great difficulty was that unless the head fitted down on the lower uterine segment no method of induction would bring the woman into labour in a reasonable time and give the baby a chance of living. Cases in which the head did not fit well into the pelvis should be left to deliver themselves, and Caesarean section should only be done if it was absolutely necessary. He felt that the proper way of inducing labour had not yet been found out. Referring to the question of external version in breech presentations, he said that the modern tendency was probably to interfere too much. He did not agree with the method of antisepsis in the vagina before delivery, and thought that the less done in the vagina before delivery the better.

Dr. J. S. QUINN disagreed with the idea that an increase of Caesarean sections was due to induction of labour, and thought that Dr. Healy's statistics showed induction to have fewer disadvantages than Dr. Davidson was inclined to believe. He would be interested to hear the number of cases in which perforation as a means of delivery was adopted.

Dr. NIXIAN FALKNER said that although induction of labour was becoming somewhat unpopular, he felt that if the results from another type of treatment proved to be worse induction would have to be resorted to. He believed that induction was followed by a higher rate of Caesarean sections than if induction was left out altogether in cases of disproportion. In cases where the head was high and labour was induced by bougies and the stomach tube, the results might be better than in cases where labour was induced by puncture of the membranes. Dr. F. DOYLE thought that puncture of the membranes was a very old method which had been discarded and had now come into fashion again. He felt that the great difficulty was in connexion with primiparae, as it was so hard to know what they could do regarding labour. He was inclined to take the view that it was better to let them go on with labour and not resort to induction, as subjecting a primipara to Caesarean section impaired her attainment of subsequent labours. Dr. R. M. CORBET said he was often impressed by cases which were brought into hospital with disproportion in which the baby was dead, perforation was done, and the head was found on the perineum a short time later. There were many cases in which disproportion was not due to the size of the head but to its alignment. This did not include all cases, and did not explain why uterine inertia was so very much more common in the primigravida. He liked the operation of external version in an easy case, but if it was difficult he was inclined to let the case alone. He did not like delivering a primipara's breech presentation, and avoided it as much as possible. He saw no objection to performing external version early, but in elderly multiparae he thought that this operation was perhaps unwise. In some of these cases he had had to do an internal version to get the case back to a breech again. He was against doing internal version for disproportion in primigravidae, and felt that the more induction of labour was done the less one tended to be dogmatic about it. He personally used induction a good deal, and had very rarely been sorry he had used it, while he had come across many cases in which delivery was

very difficult, and he had felt that if he had induced the patient sooner delivery would have been very much easier.

Dr. HEALY, in reply, said he thought that better results could be obtained when it was possible to allow patients to have spontaneous deliveries. The neo-natal deaths were practically the same after inductions and after spontaneous deliveries. He could not see any other means of avoiding Caesarean section beyond induction of labour. He hoped that when more was known about the proper time for induction better results would be obtained. He thought that external version when easy was generally a correct procedure. He mentioned one case he had seen in which the placenta became completely detached and the patient bled to death in about eight minutes' time, but he did not think accidents such as this should stop the performance of external version. He referred to a recent case of induction of labour in which there was a medium degree of flattened pelvis. The woman had had induction on three former occasions, and had had one baby by spontaneous labour. This baby, which was born spontaneously in the district, was nearly two pounds heavier than any of the babies which had been induced in the hospital. He believed that the difficulty was in knowing the proper time to induce labour. During the present year the attitude in the hospital towards induction of labour had not changed, but the number of cases suitable for induction was less than in the previous year. There was no falling off in the number of perforations as a result of either the increased number of Caesarean sections or the increased number of inductions. In New York, when statistics were compiled, induction was not regarded at all as an operation, and lower segment sections were done on all patients who were in labour, and classical sections on the remainder. Referring to the stillbirth rate with sections, forceps, and inductions, he said that the rate was best with sections and worst with forceps, inductions coming between the two. He had yet to see a case of inertia with a fixed head. In all the cases he saw the head was above the brim.

GEE'S DISEASE

A meeting of the Medical Section of the Royal Academy of Medicine in Ireland was held on November 2nd, with the president, Dr. V. M. SYNGE, in the chair.

Professor HENRY MOORE, in collaboration with Drs. W. R. O'FARRELL, J. A. GERAGHTY, M. MORIARTY, and J. MURRAY HAYDEN, read a paper on Gee's (coeliac) disease in adults. After a consideration of the literature, of the work of Hess Thaysen in Denmark, and of Bennett, Hunter, and Vaughan in England, eight cases of Gee's disease in adults were described. In seven of them (one not tested), Professor Moore said, there was a high percentage of total fat in the stools; the lowest fat percentage was 32, and the highest was 51.4 (the average normal being 18). In all patients the amount of split fat and the amount of nitrogen in the stools was normal, but some had a high soap-fat content. All had a history of diarrhoea at one time or another, two had macrocytic anaemia without achlorhydria, five had hypochromic anaemia, five had hypocalcaemia, two had tetany, and all save one had calcification of bones. In three cases the skeletal changes were so advanced as to cause multiple pathological fractures. Seven cases (one not tested) had a low blood sugar curve with the glucose-tolerance test, and the blood urea was low in five. Three had achlorhydria. Blood cholesterol was normal or subnormal. One case had hyperthyroidism and in five there was some degree of infantilism. One patient had ununited epiphyses at the 26 years of age, and another a similar condition at the age of 20; the former patient grew four inches between the ages of 23 and 25. In three cases there was a decrease in height. Lens opacities were present in two cases of seven (tested by Dr. D. O'Donoghue). The macrocytic anaemia yielded to treatment by liver extract and marmite, and the hypochromic anaemia to iron by mouth in all cases. Calcium and vitamin D in large doses, with a fat-low diet, relieved tetany. Hydrochloric acid by mouth was used for achlorhydria. The fractures united in the three fracture cases, and the calcium content of

the bones increased in all those showing bone decalcification save one. One patient died, but in six others the results of treatment were considered satisfactory, one case being too recent to form a judgement. The terms "non-tropical sprue" and "idiopathic steatorrhoea," used to describe the disease, were unsatisfactory. Gee was aware that the malady occurred in adults. Therefore, honour being given where due, the disease should be known as "Gee's disease."

Dr. E. HARVEY referred to the results obtained by McCarrison in experimental vitamin B deficiency. Rabbits put on a diet of rice developed many of the symptoms of coeliac disease. When butter was added to the diet the condition, instead of improving, grew worse, and the diarrhoea changed to steatorrhoea. He asked if the question of vitamin B deficiency had been considered in Professor Moore's cases. Dr. D. PRICE asked if the non-union of the epiphyses was the result of infantile coeliac disease which had remained untreated. Dr. GEORGEY THOMPSON said that in such a complex syndrome as Gee's disease there was almost certainly some fundamental underlying factor common to all cases and from which all the features of the syndrome resulted. The probable primary fault was defective fat absorption, resulting in the fixation of calcium in the intestinal contents. From this would follow the defective calcium absorption and the resulting abnormal calcium metabolism producing the clinical features of bone disease and tetany. He drew attention to two peculiarities of fat absorption—namely, the fact that the molecule of fatty acid was very large compared with molecules of hexose or amino-acid in the case of carbohydrate or protein absorption, and, secondly, the fact that fat was largely absorbed by the lymphatic vessels, whereas the other foodstuffs were absorbed by the blood. He suggested the estimation of changes in the blood fat following fat meals as a method of throwing light on the condition. Dr. W. A. MOORE asked why, in a case of his, there was no sign of bone decalcification, in spite of steatorrhoea of six years' duration. There was a typical blood picture of pernicious anaemia, but no achlorhydria. Dr. ALAN THOMPSON wanted to know if any examination of the faeces had been made for bile salts, and if the cases showing macrocytic anaemia had shown any evidence of central nervous system changes.

GROWTH OF *B. COLI* IN WATER

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on October 19th, with the president, Dr. W. R. O'FARRELL, in the chair, Professor J. W. BIGGER read a paper on "The Growth of Coliform Bacilli in Water."

Professor Bigger said that the organism with which most of the work was done was almost a typical *B. coli*. This organism grew in autoclaved Vartry water in flasks which were kept at 37°C., the counts rising from an initial level of from 20 to 2,000 per c.cm. up to almost half a million per c.cm. Periods of growth with high counts alternated with periods in which the count fell to 0 per c.cm. At 22°C. the bacillus grew and remained alive for more than 200 days. It was shown that the growth of the bacillus did not occur in distilled water, but did in a solution in distilled water of the dry residue obtained by evaporating tap-water. A number of other coliform bacilli of various types also grew in tap-water, and the bacillus chiefly used was capable of growth in water obtained from Belfast and Bohernabreena as well as in Vartry water. Professor Bigger pointed out the importance of the phenomenon in connexion with the bacteriological examination of water supplies.

The PRESIDENT said that it was very interesting to note the length of time that bacilli lived in water, and the fact that in some waters bacilli grew and in others they did not seemed to show that there was some solid deposit present in the water in which they did grow. He asked whether, if water was left lying in a pipe for a long time, there would be any increase in the number of bacilli in it which would be formed by the water lying in the pipe, and if that water would show similar peaks to those

shown in the experiments carried out by Professor Bigger.

Professor W. D. O'KILLY referred to some experiments which had been carried out some years ago by Dr. Houston and Dr. Coplans. Dr. Houston said that if water was stored for a certain length of time the bacilli present in it died, while Dr. Coplans said they did not. At the end of the experiments no satisfactory conclusion was arrived at. He referred to the view of the utilization of atmospheric nitrogen, and also to the "cannibalistic" view, and asked which Professor Bigger considered the more satisfactory. He also asked if there was any difference in the growth of the organisms in bottles and in flasks.

Professor T. T. O'FARRELL drew attention to the reports of the Metropolitan Water Board, recording the experiments of Dr. Houston, in which it was proved that artificially grown bacilli had a greater vitality than those obtained freshly from carriers. The fact that Professor Bigger had used stock laboratory strains might have some influence upon the experiments. As to the peculiar diminution and subsequent increase in the number of organisms he suggested the following considerations: (1) In the primary growth an inhibitory substance was produced causing the diminution, but the breaking down of the bacilli offered a new pabulum and hence the increase. (2) That the culture used contained two varieties of organisms, analogous to "rough" and "smooth," one type being reduced and the other enhanced. (3) A change might have taken place in the reaction of the water. Dr. W. P. O'CALLAGHAN said that the growth curves obtained in these experiments by Professor Bigger were of the order one was accustomed to find in these circumstances—that is, microbial growth in culture media. He asked if the flask cultures had at any stage been investigated for evidence of a lytic principle, since uniform results had not been obtained with the several culture strains in different water media, and also the frequencies of the total counts and the time intervals of the cultural counts where the graph values read zero. Dr. ALAN THOMPSON said it would be interesting to take a flask at peak of growth and the same flask at zero, and see if the amount of substance of inorganic body and bacterial body was the same. He mentioned the possibility that the microbes might be growing on water and gas, and turning into inorganic solubles. Dr. J. MACGRATH asked how Professor Bigger made sure that the organism he was dealing with was not a mixture of different types. He referred to the possibility of diluting Vartry water with different amounts of ordinary water, and said he thought the organisms reached a certain stable point beyond which they did not increase. He asked if the speaker had tried adding twice the amount of residue to a flask, and said he thought this might bring the top peak higher. Dr. G. C. DOCKLARY suggested that if nitrogen estimations were done early and again at a later date it might be a help.

Professor BIGGER, in reply, said that he had no data which would lead him to be in favour of the atmospheric nitrogen view or the cannibalistic view, but he thought that once the first step was taken the cannibalistic view might be quite a possibility. There was no difference at all in the growth of the organisms in the bottles or in flasks. His impression was that water which he had obtained from Belfast was much better for growth than Vartry water was. He had had no failures in the secondary or tertiary samples.

Mr. J. F. Jennings, F.R.C.S., who died on July 5th, left estate of the gross value of £47,660, with net personally £45,790. Subject to a legacy of £500 to his wife, he left the whole property in trust for her for life, and then to St. Bartholomew's Hospital for the endowment of beds or the foundation of scholarships for medical students.—Mrs. Elizabeth Fountaine of Watford bequeathed £2,000 to Guy's Hospital, the income to be applied to the Students' Exhibition Fund in such a way as to commemorate her late husband, Dr. David Fountaine, who was a medical student there.—Mr. W. M. Barnes of Malvern bequeathed a sum not exceeding £7,000 to his trustees, to be devoted to such medical research work or religious institutions as they may think fit.

CORRESPONDENCE

Dilating the Cervix in Placenta Praevia

SIR,—I was horrified to read in your issue of November 10th (p. 884) the suggestion that the cervix should be dilated in placenta praevia. Dr. W. J. Young considers that "over a score" of cases is a considerable experience. Such a letter as his is bound to be responsible for an increase in the maternal death rate if the treatment he suggests is carried out by other practitioners.

The cervix should never be dilated for placenta praevia, even though Dr. Young has "got away" with it in over a score of cases.—I am, etc.,

BETHEL SOLOMONS, M.D., F.A.C.S. (Hon.).

Dublin, Nov. 10th.

Mortality from Haematemesis in Peptic Ulcer

SIR,—I have read with much interest the valuable statistical review of haematemesis in the *Journal* of November 10th (p. 858) by Dr. Lloyd Davies and Mr. R. W. Nevin. While they compare their series with those dealing specifically with the mortality from haematemesis in peptic ulcer they have not divided the cases into aetiological groups, for reasons which appear to them to be adequate. It must be pointed out that an error is thereby introduced, and that correction of the figures for fatal cases, at any rate, is possible if post-mortem examinations are carried out. It is by no means clear what they mean by their mortality percentage. Is it the mortality from haematemesis from all causes, or is it the percentage arrived at after excluding cases proved to have a disease other than peptic ulcer? In any case comparison with the series quoted by the writers seems hardly justifiable.

While agreeing with the writers that "when considering the prognosis from any disease it is necessary to carry out a statistical investigation of a large number of cases," I can hardly condone their omission of my own series which was recorded in the *Lancet* (1927, ii, 168, and 1932, ii, 720). In this analysis every case admitted to the medical wards of the General Hospital, Birmingham, for the treatment of haematemesis as the leading symptom between the years 1902 and 1931 was included—a total of 649 cases. Seventy-one cases were discarded as being due to causes other than peptic ulcer, and the mortality was calculated for a total of 578 cases of peptic ulcer. The results may be summarized as follows:

Number of Cases	Deaths from Haematemesis	Mortality
240 males	39	16.2%
338 females	23	6.8%
Total = 578	62	10.7%

At the time of my original analysis in 1927 haematemesis in peptic ulcer was not regarded very seriously, and my figures excited some comment but little expressed agreement; subsequent reviews in this country have confirmed my suggestions as to the gravity of the condition, and indeed have shown the experience in London to be even worse than that in Birmingham.

Apart altogether from the establishment of haematemesis in peptic ulcer as a very grave complication, interesting points arise which give food for thought. I was able to show that at every three-year period since 1906 the mortality in women was less than half of that in men. I feel tempted to think that the explanation of

one of the ward sisters contains much wisdom. She had herself noticed that men did not do so well as women, and attributed it to the temperamental differences between the sexes: while a female patient will lie quietly and contentedly in bed, the male patient tends to be fidgety and impatient at his enforced inactivity, restless in both mind and body.

In 1927 I drew attention in the Birmingham figures to a steadily rising percentage mortality in both sexes since 1902. The cause of this must remain a matter of speculation, as so many factors are involved; but there appeared to be one marked difference between the treatment of cases, both from a study of treatment sheets and from a survey of the standard textbooks of the day, in the early years of the century and that in more recent years—I allude to the use of morphine. Morphine was apparently reserved for the relief of pain, whereas it is now nearly always given. There are theoretical objections to its use—perhaps not founded on unimpeachable physiological premisses—in that it tends to relax the stomach and to abolish that rugosity which should surely aid in blood-clotting over the bleeding spot, and that it may produce pylorospasm in some persons. I advised a caution in its use without actually incriminating it as the main factor in the rising death rate. My doubts as to the advisability of giving morphine are not shared by many, and its administration is still advocated, and by some in large doses and combined with hyoscine so as to cause practically a mild narcosis comparable to "twilight sleep."

It would be of value to have an analysis of the mortality from haematemesis in peptic ulcer with a careful study of the amount of morphine and other narcotics employed in each case: the advocacy of the "semi-narcosis" treatment of haematemesis by certain of the London physicians, and the considerably heavier mortality in the various series published from some of the London hospitals, may have a demonstrable correlation.—I am, etc.,

ERNEST BULMER.

General Hospital, Birmingham, Nov. 10th.

Local Treatment of Coryza

SIR,—It was with great pleasure that I read Dr. W. C. Spackman's letter in the *Journal* of November 3rd (p. 835), for he has drawn attention to one of the most curious inconsistencies of medical practice.

In acute inflammatory conditions one of the main objects of treatment should be to produce a hyperaemia of the affected part, so as to reinforce the defences of the body and defeat the invading organisms. The hot stupe, of course, is the time-honoured method of accomplishing this, but other means, such as Bier's passive hyperaemia, show the end in view. But in dealing with acute inflammation of the nasal mucosa the ordinary prescriptions for "oils, inhalations, sprays, pastes, and snuffs" which contain adrenaline, ephedrine, menthol, or other vaso-constricting agent have precisely the opposite effect. An anaemia of the mucous membrane is produced.

The reason for the popularity of such treatments is clear. Vaso-constriction causes shrinkage of the turbinates, which are congested in an effort to fight the infection; this makes the patient considerably more comfortable for the moment, and relief of the outstanding symptoms is mistaken for cure of the disease. Nasal respiration is restored and secretion is diminished—but at what a price! The vaso-constricting agent causes the retirement of the home forces and leaves the invading organisms in possession of the field. Apart from the increased likelihood of bronchitis, sinusitis, etc., there is grave danger of the infection settling down and becoming chronic, instead of spending itself in one battle royal. I am convinced that

the prevalence of chronic nasal infections is due in no small measure to the use of such drugs during acute coryza.

The medical profession is not entirely responsible for this, for the advertisements of commercial firms have made the public "catarrh-conscious," and have taught it to use a "cold cure" or "catarrh remedy" in acute coryza. But the medical profession has so far failed to condemn such measures with the unanimity with which it ought, and by silence on the subject it seems to have given its consent. It is to be hoped that Dr. Spackman's letter may awaken the medical conscience and be the start of a reorientation of opinion on this very important subject.—I am, etc.,

Dublin, Nov. 8th.

R. R. WOODS.

SIR,—The recent correspondence on this subject suggests to my mind that the therapeutic of the common cold threatens to rival in complication that of asthma. My experience, both in my own person and in my practice, convinces me that the ingestion of alkalis in considerable quantities diminishes the symptoms, cuts short the illness, and prevents complications such as Eustachian catarrh and tonsillitis. The treatment is an old one, but in my opinion the dosage was inadequate. Common colds repeatedly were followed in my own case by such complications until I adopted this alkaline treatment, which amounts to the ingestion of a teaspoonful of sodium bicarbonate dissolved in a tumbler of water, a like dose being kept at the bedside for sipping at night. This practice was based upon the idea that my own alkalinity was diminished, and results appear to support this. It is well known that the taking of a meal reduces the symptoms of a cold, as I think, by raising the alkaline tide, thanks to acid gastric secretion. And it is significant that recent research has shown that asthmatic attacks are associated with reduction of normal alkalinity. I make the suggestion that the alkaline treatment should be given a more general trial before resort is had to the many remedies enumerated in the recent correspondence.—I am, etc.,

London, W.1, Nov. 10th.

BERNARD E. POTTER.

Female "Bleeders"

SIR,—I should like to thank your three correspondents (October 20th, p. 744) who made comments on my letter of October 13th (p. 700). I must apologize for the fact that the information I gave, though quite correct, has proved incomplete. The father of the Winsford branch of the family was taken by relatives when his mother died—that is, when a day old—and has had practically nothing to do with his brothers and sisters since. In view of the interest shown and the absence of mention in your columns of any further female bleeders, I have done my utmost to obtain the fullest information I could about this family. With much difficulty I persuaded the mother to visit, at my expense, all her husband's known relations and find out all she could about them and the matter of bleeding. Unfortunately, the family are rather shy about the matter, and asked particularly that I should not make this investigation personally. She visited three different localities for the purpose, and seems to have taken an intelligent interest in the matter; so I hope that the revised family tree I give below is not merely correct but complete. It provides somewhat more material for those interested in the laws of inheritance, and suggests that the coming generation should provide a very pretty objection in Mendelism.

From the inquiries made there seems no doubt that the grandmother was a true bleeder—scratches, etc., bleeding profusely and for a long time, as in the case of her

granddaughters. The enlarged tree shows that the mother is not a female carrier, for it is inconceivable that three brothers should each marry female carriers, and the parents, grandparents, and numerous relations of the mother have lived in this town and are known to be normal. While the grandmother lived at Barton near Northwich, I have not been able to find out from what part of the country she originally came, for it would have been interesting to inquire whether any collateral families exist with a similar defect.

* Unknown. † Nine children, no bleeders among them.

As regards the actual defect itself, I have, as suggested by Dr. Garland, examined those members I could, and only in one did I find anything suggestive—a minute bright red spot just anterior to the right tonsil. Whether this is sufficient to clinch the diagnosis of hereditary telangiectasia I do not know, but I should be very interested to hear, especially if the diagnosis will lead to any effective treatment.—I am, etc.,

Winsford, Cheshire, Nov. 3rd.

W. N. LEAK, M.D.

Differential Diagnosis of Chronic Rheumatic Disease

SIR,—Dr. H. Warren Crowe's communications with regard to his activities at the Charterhouse Clinic are always of interest. In the letter published in the *Journal* of November 10th (p. 884) he announces, however, a new pathognomonic sign for differentiating early osteo-arthritis from other forms of arthritis. I would like respectfully to suggest to him that he is mistaken in believing this sign to be either new or reliable.—I am, etc.,

London, W.1, Nov. 12th.

W. S. C. COPEMAN.

X-Ray Examination of Empyema Cavities

SIR,—In the admirably lucid and concise account of his method of examining empyema cavities which Mr. Denis Browne gives in the *Journal* of November 3rd (p. 807) it would appear that one consideration is omitted—namely, the condition of the underlying lung.

There will be general agreement with his conclusions as to the nature of the process of cure by adhesion of the two pleural surfaces, and failure of cure due to thickening and stiffening of the walls of the cavity. It seems to me, however, that the latter condition, while in the majority of cases arising as he suggests, may in a minority be due, not to too early closure of the wound and subsequent filling of the cavity with discharge, but to too prolonged drainage, the cavity being filled with air through the wound, and thus kept open until its walls thicken, and no cure is possible save by the process advocated. I would put forward the suggestion that the "impressively quick cures" to which Mr. Browne refers occur in those cases where the discharge rapidly ceases at a time when the walls of the cavity are still pliable and the underlying lung expansile, that allowing the wound to close at this juncture enables the lung underneath to expand so that the visceral and parietal layers of pleura adhere, thus constituting cure according to the standard laid down.

Further, I believe that cases in which this is likely to occur may be identified by ordinary clinical and radiological examination of the lung. Surely it is better to attempt to assess the possibility of rapid cure rather than apply the same treatment to all cases on the ground that it is for the benefit of the majority.—I am, etc.,

Brighton, Nov. 11th.

A. DUFF, M.D., F.R.C.S. Ed.

Ingrowing Toe-nail

SIR,—In the *Journal* of August 11th (p. 262) you reviewed in an annotation the results of various operations for ingrowing toe-nail. Many years ago I pointed out that the nail was normal and that the term "ingrowing nail" was a misnomer.

To cure it quickly and effectively remove the soft tissues that are being pushed into the nail. Remove a flap of skin only from the dorsal surface of the lateral border. Insert a scalpel just beyond the posterior extremity of the lateral edge of the nail; hold it vertically and cut away the whole of the lateral border, including the skin and soft tissues of the plantar portion; cover the raw surface with the skin flap. Raise the lateral edge of the nail and keep it above the level of the skin flap by a piece of lint for a few days. Any failure to cure would be due to insufficient removal of lateral border. To cure early cases insert pledgets of cotton-wool very gradually under lateral border so as to raise it away from the injured soft tissues. This action, together with proper footwear, will suffice to cure most early cases.

—I am, etc.,

W. KENT HUGHES, M.B.LOND., F.R.A.C.S.

Melbourne, Sept. 27th.

Position of Patient for Tonsillectomy

SIR,—During a recent visit to Vienna I noticed that it was the routine practice in Professor Neumann's clinic for the patient to be placed in the upright position for the operation of removal of tonsils and adenoids, both for general and for local anaesthesia. In Great Britain the horizontal position with extended head is commonly used when a general anaesthetic is given, but a vertical position for the operation under local anaesthesia. The vertical position is definitely uncomfortable for the surgeon, and I fail to see any advantage for the patient.

It has been my practice for the last three or four years to have the patient in the horizontal position, and to use a Davis-Boyle gag for the operation under local anaesthesia. I have not found the patient complain of the Davis-Boyle gag, nor of the position; in fact, it is preferred by the patient, as it tends to avoid sensations of faintness.

The following points are in favour of the horizontal position: (1) The blood and saliva flow back by gravity into the nasopharynx, where it forms a pool, which can be kept clear by means of suction through a catheter passed through the nasal passage. (2) The danger of blood clot, or small fragments of tonsil and adenoid tissue, getting into the lower respiratory tract is obviated, in that such fragments cannot but fall back downwards into the nasopharynx. (3) The head of the patient is very much more readily controlled, as it cannot be pulled backwards away from the surgeon if the patient experiences unpleasant sensations.

I should like to know why the vertical position is chosen by so many surgeons, and whether they think there are important contraindications to the horizontal position. I would suggest that the greater comfort of the surgeon is of material advantage to the patient.—I am, etc.,

S. W. GRIMWADE,

Surgeon Captain R.N. (ret.).

London, N.11, Nov. 5th.

Tobacco Angina

SIR,—Much has been written concerning coronary occlusion, but no attempt seems to have been made to classify this disease in separate groups. I should like to indicate one group which I consider forms a definite syndrome. (1) Anginal pain on exertion; (2) a history of excessive tobacco smoking; and (3) terminal attacks of coronary occlusion, frequently associated with glycosuria and acidosis. I would suggest that the pathology of the condition is similar to that encountered in cases of obliterative arteritis in the legs of heavy smokers associated with intermittent claudication—namely, a direct action of nicotine upon the blood vessels supplying the heart muscle and pancreas.—I am, etc.,

London, W.1, Nov. 6th.

JOHN H. HANNAN, M.D.

Use of Fascia Lata Sutures

SIR,—Though he makes no reference to it, Mr. W. S. Brindle will find the description of a simple fascia cutter of my invention in the *Journal* of August 1st, 1931 (p. 194).

This instrument, which was evolved gradually prior to publication, gave, and continues to give, me good satisfaction. In it is incorporated the very feature the lack of which Mr. Brindle points out in the Meath instrument—namely, in subcutaneous fasciotomy, the liberation of adhesions normally present between the skin and fascia. My fasciotome has a quadrilateral fenestration at its cutting end, and its upper flat margin strips the skin off the surface of the fascia. This dispenses with the need of a second part to the instrument. Further simplification is also possible with it, as the second incision advised by Mr. Brindle can usually be dispensed with as follows. If, as the cutting comes to an end, the handle (made at a slight angle to the shaft) is depressed against the thigh and pushed on with a sudden jerk, the upper end of the strip usually yields and is cut free without the need for an upper incision. In regard to late results I find, on examining many of my cases later, no complaint of disability.—I am, etc.,

Bristol, Nov. 5th.

A. WILFRID ADAMS.

The Pre-asthmatic Phase

SIR,—In a communication of mine to the *Journal* (July 28th, 1934, p. 192) I referred to a probable pre-asthmatic phase in the case of asthmatic children. The following case history is interesting in this respect.

In 1930 I attended a boy, R. B., aged 3 years, the younger of a family of two boys, suffering with laryngismus stridulus. The condition cleared within two days, and he remained well till February, 1932, when he developed a similar but more severe attack, followed by bronchopneumonia. Recovery was slow but progressive. On September 1st, 1932, I approached his parents with a view to further investigation. I examined him, and found him to be apparently in a good state of health, but a differential leucocyte count showed an eosinophilia of 9 per cent. In view of this and of his past history I ventured to label him as a potential asthmatic. All went well until March, 1934, when he developed acute bronchitis, with a 2 per cent. eosinophilia during the pyrexial stage. Within a week the symptoms subsided, while the eosinophilia rose to 10 per cent. During April, 1934, he was sent from another source to the local anti-tuberculosis clinic for investigation, but the findings were negative. I saw him next on August 16th, 1934, and on this occasion he was suffering from his first attack of typical asthma. Since then he has had numerous attacks.

Such a history is not isolated, but illustrates a pathological sequence common amongst asthmatic children in their pre-asthmatic years. There is abundant evidence of increased sickness incidence during the early years of

ordinary school life, and this is particularly applicable to the allergic child, who often develops the classical phenomena of asthma during this period. In view of the excellent results obtained from the open-air school line of treatment in established cases, it would appear to me justifiable to segregate by school age children suspected of potential asthma, and give them the benefit of an environment and routine control that does offer some hope of success as a preventive measure.—I am, etc.,

Birmingham, Nov. 3rd.

A. W. DOCKAR.

Obituary

DAVID WOOD INGLIS, M.D.

The death of Dr. D. W. Inglis, which occurred on November 2nd, will leave a great void in professional circles on Tyneside, for he was not only a very well known and highly respected practitioner, but a worthy representative of that scholarly type of doctor so often the product of the Scottish universities in the old days. As a young man he went up to Edinburgh from his home near Biggar in Lanarkshire to take an Arts course with the intention of going in for the teaching profession. To that end he took his M.A. in 1876, and had it not been for the influence of a fellow lodger, who was himself a medical student, he might never have thought of medicine as a vocation. It was the large numbers of medical students and the consequent lack of clinical opportunities in the Edinburgh of those days that made him select Glasgow for his medical studies. There he took his M.B. and C.M. with high commendation, and later his Doctorate. He afterwards held house appointments in the Western Infirmary, and for a time was an assistant surgeon to the dispensary for diseases of the skin. About fifty years ago he went to Tyneside, and had lived and worked in Hebburn and district ever since. About three years ago Dr. Inglis retired from active practice, but he kept on his appointment as factory surgeon, largely because of the interest which he found in keeping in touch with men with whom he had worked amicably for so many years. As a J.P. he was most assiduous, and attended the courts regularly.

Although an excellent practitioner, most helpful and considerate, his real interest was in the humanities, and all his spare time was devoted to the study of literature. He was not only a good classical scholar, but was also very fond of German, which he read fluently. Years ago he had travelled abroad a good deal, but more recently nearly all his holidays were spent in the Island of Skye, and up till about two years ago he regularly did some climbing among his beloved Coolins. Dr. Inglis died in his eighty-first year, after an operation for a fulminating type of appendicitis: he was only laid up for a few days, and up to the onset of this fatal illness he was active in every way. His was a character whose influence in the higher things of life seemed to permeate all around. A delightful habit of conciliation made him welcome everywhere, while a consistent equanimity and a never-failing sense of humour were helpful in many trials. He had been a member of the British Medical Association for twenty-seven years.

He will be sadly missed by a large circle of friends, and by none more than his fellow-members of the "Sphalma."

A correspondent writes:

The death of my old friend Dr. David Inglis of Hebburn-on-Tyne, only a fortnight after spending a week-end with him in Scotland, should not be allowed to pass without paying some slight tribute to his memory. We went away twice a year, in spring and autumn, and he has motored with me for the past seven or eight years. One saw David Inglis at his best when he was taking

a country walk of sixteen to twenty miles, and when one heard him discussing all things: his knowledge was encyclopaedic, but he had a particularly intimate liking for the plants and animals that one sees in a tramp of miles. His interest extended to geology, and he knew a great deal about the characteristics of the Lowlands. Anything antiquarian appealed to him—from an inscription in Dryburgh Abbey from Horace's Odes, "*Amara lento tempora risci*," to the church of Samuel Rutherford at Anworth. All the places we recently saw together—the castle of the Maclellans in Kirkcudbright, Dundrennan Abbey, Sweetheart Abbey, and Lanercost Abbey—he knew by frequent visits, and he showed off their features with enthusiasm. Perhaps his greatest interest, however, was in place names. He had a working knowledge of Gaelic, and knew enough of the languages of the Norwegians and Danes to place their occupancy in this country. To hear him speak on the local names of places he visited showed what a grip he had of his favourite subject. Inglis was a mountaineer fifty years ago, and a keen member of the Alpine Club. For thirty years he had gone to Skye, climbed the Coolins, and fished from his favourite hotel; and he knew every stream and tree in the district. To hear him talk of his mountaineering experiences was a treat, for he shone as a conversationalist. Alas that such men should die with their abundant knowledge and philosophy of life. He was a good companion to the last.

J. H.

Dr. WILLIAM HEWSON MOOK died suddenly, from pneumonia and cardiac failure, on November 3rd, at the age of 56. He was assistant professor of dermatology, St. Louis, Mo., and the author of many papers on dermatological subjects. Dr. Mook came to France in 1917 with the American Expeditionary Force, and was first attached to the R.A.M.C., among whose members he made many friends. Subsequently he was appointed chief dermatologist to the American Army in France.

Dr. THOMAS ALEXANDER BROWN, who died at his home in Rhos-on-Sea on November 8th, was a well-known practitioner in the Midlands. He practised in Birmingham for many years and later at Sutton Coldfield. Born in Dunfermline in 1860, he belonged to a family of doctors: he had three brothers who were doctors, one of them his twin. After some years of working with Duncan, Flockhart and Co., Dr. Brown studied medicine at Edinburgh University, and graduated M.B., C.M. in 1884; he also took the M.R.C.S., L.R.C.P. immediately afterwards. He was for a year senior demonstrator of anatomy at Surgeons' Hall, Edinburgh, and, after being an assistant to a Keswick doctor, he settled down at Small Heath, Birmingham, where he quickly developed a very large practice. He subsequently practised at Sutton Coldfield, until his health gave way, when he retired to live at Rhos-on-Sea, North Wales. Although for some years past an almost helpless cripple, he never grumbled, but preserved to the very last his happy, cheerful disposition. His loss will be mourned by a vast number of patients and friends. He is survived by his wife and a son and daughter, the son practising as a doctor at Rhos-on-Sea.

We regret to announce the death in Liverpool, on November 1st, of Dr. GEORGE GILBERT FLEMING, of 37, Maresfield Gardens, N.W.3, late surgeon of the s.s. *Homer*, White Star Line. Dr. Fleming, who was 65 years of age at his death, received his medical education at Dublin, where he graduated B.A., T.C.D., in 1891, proceeding M.D. in 1894, the same year in which he took the M.B., B.Ch., B.A.O. He was appointed to the Australian service in April, 1903, and resigned two years later. In 1908, after leaving the *Persic*, he entered the New York service, and subsequently worked on a number of these liners. From 1919 to 1921 he was on the *Baltic*, and continued on the transatlantic service until 1931, being appointed to the *Homer* in 1927. On the death of his wife in 1931 he resigned.

Universities and Colleges

UNIVERSITY OF OXFORD

Brian Gilmore Macgrath, M.B., B.S., B.Sc., of Adelaide University and Magdalen College, has been elected to the Staines Medical Fellowship at Exeter College.

UNIVERSITY OF LONDON

Dr. A. M. H. Gray has been elected Dean of the Faculty of Medicine for 1934-6.

A meeting of the Court, held on November 7th, with the Deputy-Chairman (Mr. Loney) presiding, was informed that the Essex County Council had decided to make a grant of £33,000, payable over ten years, towards the erection of new buildings in Bloomsbury. The Court has conveyed its most cordial thanks to the Essex County Council and Education Committee for their munificent gift. The Court accepted with gratification a donation from the Worshipful Company of Tallow Chandlers towards the ceremonial hall to be built on the Bloomsbury site. The thanks of the Court were conveyed to the Middlesex Education Committee for grants towards university extension courses and tutorial classes.

The title of the University Chair of Obstetric Medicine tenable at University College Hospital Medical School has been changed to "University Chair of Obstetrics and Gynaecology tenable at University College Hospital Medical School."

Dr. Sophia Jevons has been nominated for appointment as Governor of the Strand School.

The following appointments have been made: Dr. Amy M. Fleming to the University Chair of Obstetrics and Gynaecology tenable at the London School of Medicine for Women as from October 1st, and Professor George Grey Turner to the University Chair of Surgery tenable at the British Post-Graduate Medical School as from October 1st or such later date as may be found practicable.

Brown Institution Lectures

The Brown Institution Lectures for 1934, entitled "Primitive Forms of Life," will be delivered by Dr. F. W. Twort, F.R.S., professor of bacteriology in the University and superintendent of the Brown Institution, at the London School of Hygiene and Tropical Medicine on December 10th, 12th, 14th, 17th, and 19th, at 5 p.m. Admission free, without ticket.

The University Medal in Branch I (Medicine) at the M.D. examination for internal and external students, July, 1934, has been awarded to Dr. Leslie George Norman (University College Hospital), and the University Medal in Branch I (Surgery) at the M.S. examination for internal and external students, July, 1934, to Mr. David Trevor (St. Bartholomew's and Charing Cross Hospitals).

UNIVERSITY OF LIVERPOOL

The Council of the University of Liverpool has conferred the title of Professor Emeritus upon Dr. J. M. Beattie, formerly professor of bacteriology, and upon Dr. John Hay, formerly professor of medicine.

UNIVERSITY OF GLASGOW

At the graduation ceremony held on November 3rd the following degrees were conferred:

D.Sc.—N. Morris, M.D.

M.D. (with commendation)—H. B. W. Morgan.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a special meeting of the council, held on November 5th, the Honorary Fellowship was conferred on Emeritus Professor Archibald Donald (Alderley Edge) and Sir William Josiah Smyly (Dublin).

Dr. W. F. T. Haultain (Edinburgh) was admitted to the Fellowship of the College, and the following were admitted to membership: Frederick Arthur Clift (London), David William Currie (Leeds), Morgan David Arwyn Evans (Cardiff), William Dawson Galloway (Holmefirth), Lionel George Higgins (Woking), Russell Norfolk Howard (Melbourne), Robert James Kellar (Edinburgh), John Harold Peel (London), Jack Polonsky (Capetown and Liverpool), Arthur Lloyd Potter (Wigan), John Lekan Scholes (Melbourne), Percy Norman Leonard Seager (Dublin), Thomas Francis Todd (Preston), Charles Henry Walsh (Liverpool), Charles Alexander Whitfield (Tidworth), Bryan Williams (Birkenhead), James Smith Young (Kilmarnock).

The following were admitted, *in absentia*, to the Foundation Fellowship: F. Brown Craig (Sydney), Benjamin Philp Watson (New York); to the Foundation Membership: William Allan Dafee (Toronto); and to Membership: John Nicholas Chesterman (Sydney), Thomas Frederick Corkill (Wellington, N.Z.), Frieda Ruth Highway (Sydney), Nora Proctor Sims (Baluchistan).

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary Council meeting was held on November 8th, when the President, Sir Holburt Waring, was in the chair.

The President reported the award of Mackenzie Mackinnon Research Fellowships to E. G. L. Bywaters and L. C. Bousfield, both Members of the College, for a research into rheumatoid arthritis, to be carried out in the Middlesex Hospital Medical School.

Diplomas of Membership were granted to A. H. Khan, S. H. Awad, and 123 other candidates whose names were published in our issue of November 3rd (p. 838) in the report of the proceedings of the Comitia of the Royal College of Physicians of London, as were the names of the eight candidates to whom the Diploma in Public Health has been granted, and the name of the candidate who has received the Diploma in Gynaecology and Obstetrics.

The Buckston Browne Dinner

The seventh annual Buckston Browne Dinner of Fellows and Members was held in the library of the College on November 8th, with the President, Sir Holburt Waring, in the chair. In the course of a general welcome to the guests the President said that the dinner had been founded by Sir Buckston Browne to promote good fellowship among the various diplomates of the College. He then gave an account of the activities of the College during the past year, and emphasized particularly the surgical research in progress in the laboratories in Lincoln's Inn Fields and at the Buckston Browne Farm at Downe, enumerating the various researches being carried out by scholars and others. He also referred to the Proffit Trust for cancer research, in connexion with which the College has set on foot two parallel researches—the radium beam therapy at the Radium Institute and the mass radiation with deep x rays at the Mount Vernon Hospital. Turning to education, Sir Holburt said that the examinations for the Membership and other diplomas had been carried on as usual, and that primary examinations were being conducted over-seas this winter by examiners sent out from England to Australia, New Zealand, and India, large numbers of candidates having entered in each case. In the College itself a great loss was caused by the retirement of Mr. S. Forrest Cowell, who during a period of thirty-three years as secretary had missed only one meeting of the Council. Mr. Henry George, the articulator, had also retired, and carried with him the good wishes of the many examiners and examination candidates with whom he had come into contact. Finally, the President referred to the progress of the Royal Australasian College of Surgeons, whose new building in Melbourne he, as President of this College, was formally to open next March. Under the circumstances it was appropriate that he could couple with the toast of "The Guests" the name of the Right Hon. S. M. Bruce, High Commissioner for Australia. The High Commissioner for Australia expressed thanks to the College on behalf not only of the guests present, but also of Australia, and particularly of the Australasian College of Surgeons, for the presentation of a replica of the mace of this College, for the holding of examinations over-seas, and for the coming visit of the President to Australia to open the new College. The interest shown by actions such as these was of the utmost value in the encouragement of surgery over-seas. In proposing the health of the donor the President spoke not only of the dinner, but also of the Surgical Research Farm at Downe which Sir Buckston Browne had endowed. The farm buildings were now nearly complete, and could provide accommodation for almost any animal required by research workers, except perhaps the elephant. Sir Buckston Browne replied in suitable terms, and expressed his thanks to all the officials who had helped to make the dinner a successful institution. After dinner the guests went round the museum, where special exhibitions had been arranged under the direction of Dr. John Beattie, its conservator and director of research.

The following is a complete list of those present:

Council.—Sir Holburt Waring (President), Mr. Walter Trout and Mr. A. H. Burgess (Vice-Presidents), Mr. Ernest W. H. Groves (Bristol), Sir Cuthbert Walker, Mr. F. J. Smeaton, Mr. C. H. Fagge, Mr. W. Sampson Handley, Mr. G. E. Gaskell, Mr. Victor Bonney, Mr. G. Grey Turner (Newcastle-on-Tyne), Mr. H. S. Lett, Mr. Leonard Gamgee (Birmingham), Mr. R. G. H. H. Lett (Nottingham), Mr. R. E. Kelly (Liverpool), Mr. Graham Wilson (Sheffield), Mr. A. James Walton, Mr. A. E. Webb-Jones, Mr.

R. C. Elmslie, Mr. L. R. Braithwaite (Leeds), Mr. H. S. Souttar, and Mr. W. Girling Ball.

Fellows.—Mr. F. H. Bentley, Mr. A. M. Boyd, Sir Buckston Browne, Mr. D. A. Davies (Deal), Mr. W. D. Doherty, Mr. E. Laming Evans, Mr. E. R. Flint (Leeds), Mr. Thomas C. Graves (Birmingham), Mr. R. Vaughan Hudson, Mr. J. A. James (Bristol), Mr. C. Naunton Morgan, Mr. Cyril A. R. Nitch, Mr. C. A. Pannett (Richmond), Professor Miles H. Phillips (Sheffield), Mr. L. Carnac Rivett, Mr. Charles Roberts (Manchester), Professor Leyland Robinson (Liverpool), Mr. W. G. Rose (Derby), Mr. Cecil Rowntree, Mr. W. R. Spurrell (Tadworth), Mr. R. M. Vick, Mr. Cecil P. G. Wakeley, Mr. Norman L. White, and Dr. R. Salisbury Woods (Cambridge).

Members.—Dr. G. P. Anning (Leeds), Mr. R. E. Apperly, Dr. K. J. Aveline (Buckley), Dr. Roland Brinton, Dr. H. Allen Bulman, Dr. Ronald Burn (Richmond), Mr. C. E. Clay (Dewsbury), Dr. W. S. C. Copeman, Dr. T. B. Davie (Liverpool), Dr. Max E. Delafeld, Dr. H. E. Dyson, Mr. John L. Farquharson (Weston-super-Mare), Dr. N. S. Finzi, Dr. T. F. Fox, Dr. V. B. Green-Armistage, Dr. Charles Hadfield, Surgeon Vice-Admiral R. W. B. Hall, Mr. J. D. Hay (Liverpool), Mr. C. Bowdler Henry, Dr. Stuart Hensman, Dr. R. A. Hickling, Dr. A. B. Howitt, M.P., Dr. Bernard Johnson, Mr. Murray P. Jones (Ashford), Mr. H. C. Lees (Darwen), Dr. D. C. Muir (Hull), Mr. B. Rait-Smith (Redhill), Dr. F. H. Robbins, Mr. H. D. Rollinson (Coventry), Mr. G. W. Rose (Toronto), Dr. R. A. Rowlands, Dr. W. Sirr Sheldon, Dr. T. H. G. Shore (Plymouth), Dr. D. B. Smallshaw (Epsom), Dr. J. Forest Smith, Dr. W. B. Stanford, Dr. H. J. Stirling (Norwich), Dr. Penison Stillwell (Beckenham), Dr. R. Tilbury, Dr. H. T. M. Townsend-Whitling (Market Harborough), Mr. F. B. Winfield (Birmingham), Mr. W. L. René Wood (Ossett), and Professor Samson Wright.

Others Present.—The Right Hon. S. M. Bruce (High Commissioner for Australia), Sir Robert Bolam, Dr. Mervyn Gordon, Dr. John Beattie (Conservator), Mr. Kennedy Cassels (Secretary), and Mr. T. D. McCown.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the College was held on November 6th, when the president, Dr. Edwin Bramwell, was in the chair. Dr. J. R. Currie (Glasgow), Dr. A. G. Cruikshank (Edinburgh), and Dr. Douglas A. Miller (Edinburgh) were introduced and took their seats as Fellows. Dr. J. A. D. Iverach (Dunedin, N.Z.), Dr. J. Burnett King (Edinburgh), Dr. J. Alastair Bruce (Edinburgh), Dr. D. K. Henderson (Edinburgh), and Dr. R. F. Ogilvie (Edinburgh) were elected Fellows.

The Hill Pattison-Struthers Bursary in Anatomy and Physiology was awarded to A. T. R. Hamilton.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on November 5th, the following officers were elected:

President, Dr. J. M. Munro Kerr. *Visitor*, Mr. Archibald Young. *Honorary Treasurer*, Mr. James H. MacDonald. *Honorary Librarian*, Mr. W. R. Spodgrass.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The Poor Law Bill was read a third time by the House of Commons on November 9th. Sir Francis Fremantle expressed satisfaction at the exemption of maternity benefit from calculations of the means of applicants for public assistance. He hoped it was the forerunner of further measures next session respecting health and maternity benefits. On November 13th the Poor Law Bill was read a second time in the Lords.

On November 9th the House of Commons approved Additional Import Duties Orders, including Order No. 28, regarding importations of medical and surgical instruments. Dr. Burgin said the Order increased the import duty on these from 10 to 20 per cent. There was a very large industry in the United Kingdom, the factories of which were equipped with most modern plant. Public bodies and voluntary hospitals used almost entirely British instruments, and there was also a very considerable export trade in British-made instruments. The British preference was not to have a surgical instrument standardized and made by mass production at a low price, but a hand-forged instrument produced here. The

committee therefore recommended that there should be a 20 per cent. duty upon these surgical instruments.

The Parliamentary Medical Committee invited Dr. Addison to dine with them on November 14th to mark his re-election to the House of Commons.

The Betting and Lotteries Bill, which had already passed the House of Lords, was read a third time in the House of Commons on November 13th, and was due to receive the Royal Assent, with other measures, before the prorogation of Parliament on November 16th. On November 14th the House of Commons discussed the reports made by the Government Commissioners to the necessitous areas of Scotland, Cumberland, Tyneside, Durham, and South Wales. These reports contained references to the physical condition of the unemployed and their families in these districts.

Anti-noise Committee

On November 13th Mr. HORE-BELISHA informed Mr. Anstruther Gray that the terms of reference of the Anti-noise Committee were limited to noises arising from the operation of mechanically propelled vehicles. Examination of the problem of deafness caused by pneumatic drills was not included.

Replying to Mr. Touche, Mr. Hore-Belisha said that the Ministry of Transport had for some time been in touch with the Society of Motor Manufacturers with a view to preventing the manufacture of motor cars with inadequate or ineffective silencers. The society had also accepted an invitation to appoint a representative to serve on the committee which he had recently appointed to consider the steps that might be taken to reduce noise arising from the use of motor vehicles.

No Christmas Draws for Hospitals

During the consideration of the Betting and Lotteries Bill on the report stage in the House of Commons on November 12th, Sir W. WAYLAND moved a new clause providing that a Christmas draw promoted in a city, borough, or district to raise money for a local hospital should not be deemed to be an unlawful lottery provided that not more than one such lottery was promoted for the benefit of any one hospital in any year; no ticket was sold earlier than the month of November; no tickets were sold outside the city, borough, or district in which the hospital was situated; and no tickets were sent through the post. The clause also provided that after the purchase of prizes and payment of expenses the proceeds should be applied solely for the benefit of the local hospital, the name of which was printed on the ticket; the prizes should not be money prizes; accounts should be audited by a qualified accountant; and permission to hold the draw should be first obtained from the mayor of the city or borough or chairman of the district council. Sir W. Wayland explained that a draw held in a large works employing from 5,000 to 10,000 men would be legal under the Bill, but a Christmas draw on behalf of a hospital, whether small or large, for the sole benefit of that hospital, would be illegal. Vice-Admiral TAYLOR, in seconding the clause, said that it would be a severe blow to many small hospitals if these Christmas draws were to be made illegal.

Mr. RHYS DAVIES opposed the clause. He said that in some districts the working men paid a weekly contribution of 1d. or 2d., and in some cases up to 6d. If the clause were adopted it would destroy that practice altogether. The working men would probably drop the weekly contribution, and take a sixpenny ticket once a year. Captain HEILGERS said that while it was true the big hospitals did not want these schemes, especially in London, because they had a national appeal to which the whole country responded, the poor hospitals could not raise money in that way.

Captain CROOKSHANK, on behalf of the Government, said that it would be practically impossible to limit the sale of tickets of a lottery, authorized by a mayor of a city, to the city itself, and to ensure that no tickets were sold earlier than November. The great mass of the hospitals did not want money to be raised by lotteries. The British Hospitals Association passed a resolution at Eastbourne on June 2nd,

1931, declaring that it was "not in favour of an amendment of the law affecting public sweepstakes the purpose being for the benefit of voluntary hospitals." A great many hospitals realized that a large number of their willing subscribers would say to them, "Why ask me for a subscription? Why not have a lottery?" There would be no answer to that question.

The clause was rejected by 155 votes to 81.

Maternal Mortality.—Mr. SHAKESPEARE told Mr. Boothby, on November 7th, that a list of areas exhibiting a persistently high rate of maternal mortality was included by the Chief Medical Officer of the Ministry in his report for 1933. Of 125 maternity and child welfare authorities which functioned within the areas in question all but three provided milk or food for expectant and nursing mothers, and in one of these areas any necessary supply was provided by a voluntary society. The attention of all maternity and child welfare authorities had been drawn to the importance of this provision. Answering a similar question from Miss Cazalet, on November 8th, Sir HILTON YOUNG said it was intended to make a detailed review of the maternity services in each area of persistently high maternal mortality to determine what action was needed to render the services both effective and comprehensive. For this review he proposed to instruct expert medical officers to visit the areas concerned.

Medical Officer for Maternity and Child Welfare.—Mr. RYNS DAVIES, on November 8th, challenged the wisdom of the decision not to fill the vacancy caused by the resignation of the Ministry of Health medical officer for maternity and child welfare. Sir HILTON YOUNG replied that the Local Government Act of 1929 imposed more largely on local authorities the determination of their local administration of maternity and child welfare work. Consequently its supervision by his Department had been substantially changed in character and degree. He had decided, therefore, that on the retirement of the senior medical officer in charge of this work its supervision could best be entrusted for the future not to two higher posts, but to one. This post was held by a most experienced woman medical officer, who was directly responsible to the Chief Medical Officer of the Ministry. There was no ground for misgiving on the present arrangements for effective performance of this branch of the Ministry's work.

Dupuytren's Contraction.—Sir JOHN GILMOUR told Mr. Tinker, on November 8th, that the question of giving workmen's compensation for Dupuytren's contraction was fully inquired into in 1913 by the Committee on Compensation for Industrial Diseases, which took evidence from the Miners' Federation and others. The committee found that there was no established connexion between this condition and the workmen's employment which would justify its being scheduled. Since then no evidence had come to his notice to suggest that this conclusion ought to be reconsidered. He was prepared to consider any fresh evidence. Mr. Tinker suggested that in coal mining a large number of men were unable to follow their employment through Dupuytren's contraction, their fingers contracting into the palm of the hand.

Birth Control Clinics.—Replying to Sir Arnold Wilson, on November 8th, Sir HILTON YOUNG said, so far as was known in his Department, clinics at which advice on contraceptive methods was given subject to the limitations laid down in Ministry of Health circulars on the matter had been provided by thirty-two local authorities in England and Wales. A number of other authorities had made arrangements with the same object otherwise than by the provision of clinics.

Milk Supply to Schools.—Mr. RAMSBOTHAM told Mr. Hall Caine, on November 8th, that it was not possible to give statistical information on the operation of the scheme for the supply of milk at reduced rates in schools in England and Wales. He did not think that there had been any difficulty in getting milk approved by the medical officers, in the rural areas particularly. The Board of Education had not made it a requirement that pasteurized milk must be supplied to the

exclusion of all other types, though where the supply of sufficient pasteurized milk was available this should be supplied. Medical opinion was strongly in favour of supplying pasteurized milk where possible. On November 12th Mr. RAMSBOTHAM informed Mr. J. Duncan that the initial stages of the milk-in-schools scheme had given rise to a number of questions which it was hoped would be satisfactorily settled at an early date. The President of the Board of Education understood that, as the result of a special inquiry made by the local education authority for London shortly after the scheme came into force, it was found that about 364,000 children in that area were then receiving milk under voluntary schemes, and about 26,900 children through the local education authority's arrangements under the Education Act—a total of 390,000. Before the introduction of the scheme the corresponding figures were, approximately, 100,000 and 25,000 children, a total of 125,000. The scheme had met with an encouraging reception, and there was a general large increase in the number of children receiving milk in schools.

Dental Benefit.—Sir HILTON YOUNG told Sir Arnold Wilson, on November 8th, that the Dental Benefit Joint Committee, a voluntary non-statutory body, ceased to exist on December 31st, 1928. Subject to his general control, the arrangements for the provision of dental benefit were in the hands of a statutory body known as the Dental Benefit Council, set up in accordance with Regulations made under Section 16 of the National Health Insurance Act, 1928. These Regulations contained provisions for the administration of the benefit, including the scale of fees and conditions of service, and replaced the *Dental Benefit Handbook*, which would not be reissued.

Maternity and Child Welfare in Monmouthshire.—On November 12th Sir HILTON YOUNG informed Mr. Denman that his attention had been called to the report of the county medical officer for Monmouthshire, for 1932, which stated that the county council had ordered that the maternity and child welfare estimates should be reduced by the annual figure of £3,260; that in the following year, 1933-4, a further saving of £637 was required; and that it was necessary, therefore, to revise the scheme for the provision of milk for necessitous mothers and infants. The county council gave an assurance that the reductions referred to would not prevent the continued supply of milk to those mothers who required it on grounds of health, but he was making further inquiry into the position.

Deaths Following Anaesthesia.—On November 12th Sir HILTON YOUNG, replying to Captain Erskine-Bolst, said that the available records did not enable deaths attributable to anaesthesia to be distinguished from those occurring during anaesthesia, though not attributable thereto. For the six months ending March 31st last the deaths classified as attributable to, or having occurred during, anaesthesia included the following, in which avertin was used: three, avertin alone; one, avertin in conjunction with oxygen and nitrous oxide; one, avertin in conjunction with "gas, oxygen, and ether."

Pollution of River Tame.—Mr. SHAKESPEARE, replying to Mr. Mander on November 13th, said that the sources of the pollution of the River Tame in its passage through Willenhall had been difficult to trace, but he was informed that it appeared to arise from old culverts and impregnated subsoil. Active steps were being taken to abate the pollution, but from its nature complete abatement would take some time.

Notes in Brief

Sir Hilton Young states that the numbers of persons in Great Britain who, on December 31st, 1933, were insured for health and pensions purposes respectively were approximately 18,181,000 and 18,793,000. The number of insured persons who were under the age of 20 on December 31st, 1931, was approximately 2,500,000.

Mr. Shakespeare states that out of the £1,000,000 grant to assist rural water supply schemes £302,000 has been allocated for schemes of an estimated capital cost of £2,100,000.

Medical News

The Minister of Health, Sir Hilton Young, will be the principal guest at the annual dinner of the Society of Medical Officers of Health, to be held at the May Fair Hotel on Thursday, November 22nd, at 7.10 for 7.30 p.m. Dr. R. Veitch Clark, the president of the society, will be in the chair. Tickets are obtainable (12s. 6d.) from the Executive Secretary, 1, Upper Montague Street, Russell Square, London, W.C.1.

A meeting of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square, London, W.C., on Wednesday, November 21st, at 5.30 p.m., when papers will be read by Mr. J. E. Barnard, F.R.S., Mr. F. V. Welch, and Mr. John Smiles.

Sir Malcolm Watson will deliver the *Finlayson Memorial Lecture*, on "Some Pages from the History of the Prevention of Malaria," in the Faculty Hall, 242, St. Vincent Street, Glasgow, on Monday, November 19th, at 4 p.m. Fellows of the Faculty and medical practitioners are invited to attend.

The annual general meeting of the British Health Resorts Association will be held at 28, Portland Place, W., on Thursday, November 22nd, at 3.30 p.m., when the chairman of the council, Lieut.-Colonel R. H. Ellior, will preside.

The ninety-second half-yearly dinner of the Aberdeen University Club, London, will be held at the Trocadero Restaurant at 7.30 p.m. on Thursday, November 22nd, under the chairmanship of G. A. Morrison, Esq., LL.D., M.P. The secretary's address is 16, Tregunter Road, S.W.10.

The Master of the Society of Apothecaries of London (Sir George Buchanan) and the senior and junior Wardens (Sir William Wilcoxon and Dr. J. S. Fairbairn) have issued invitations to a reception at Apothecaries' Hall on the evening of Friday, November 23rd, to meet members of the Society of Medical Officers of Health.

The annual clinical "At Home" of the Royal Dental Hospital of London will be held at the hospital (32, Leicester Square, W.C.) on Saturday, November 24th, at 2 p.m. The dinner of past and present students will take place at 7.30 p.m. at the Trocadero, with Mr. J. Thornton Carter in the chair.

The British Science Guild announces that the Norman Lockyer Lecture, 1934, will be given on Wednesday, November 28th, at 4.30 p.m., by Professor J. B. S. Haldane, F.R.S., in the Goldsmiths' Hall, Foster Lane, E.C. His subject will be "Human Biology and its Applications." Tickets, for which there is no charge, are obtainable from the secretary, 6, John Street, Adelphi, W.C.

The next quarterly meeting of the Royal Medico-Psychological Association will be held at 11, Chandos Street, W., on Tuesday, November 20th, at 2.30 p.m., when there will be a discussion on Section 5 of the Mental Treatment Act, to be opened by Sir Hubert Bond.

A meeting of the Medico-Legal Society will be held at 11, Chandos Street, W., on Thursday, November 22nd, at 8.30 p.m., when a paper will be read by Dr. Horace Shelley entitled "Observations on some Medico-Legal Experiences in Nyasaland." A discussion will follow.

A general meeting of the Society of Medical Officers of Health will be held at 1, Upper Montague Street, W.C., on Friday, November 23rd, at 5 p.m., when there will be a discussion on "The Organization of the Domiciliary Medical Service," to be opened by Dr. J. A. Charles.

In celebration of the jubilee of the first operation for the removal of a cerebral tumour—performed by Sir Rickman Godlee at the Hospital for Epilepsy and Paralysis on November 25th, 1884—Mr. Wilfred Trotter will read a paper entitled "A Landmark in Neurology," in the Robert Barnes Hall, at 1, Wimpole Street, on Tuesday, November 27th, at 5 o'clock. At 7.30 p.m. a commemorative dinner will be held at the Dorchester

Hotel, with Lord Horder in the chair. The last day on which applications for tickets can be received is Monday, November 19th. They should be addressed to the secretary, Hospital for Epilepsy and Paralysis, Maida Vale, W.9.

The annual Benjamin Ward Richardson Memorial Lecture, arranged by the Model Abattoir Society, will be given on November 27th, at 5.30 p.m., at the Royal Sanitary Institute, Buckingham Palace Road, by Sir Leonard Hill. The society was founded in 1882, and its persistence in advocating the three objects of promoting merciful treatment of animals, advancing the health of the population, and obtaining economic management of slaughterhouses is being rewarded by their inclusion in proposals lately promulgated by the Ministry of Agriculture. Yet there remain many points regarding methods of painless killing that need careful study. The title of Sir Leonard Hill's lecture is "Electric Methods of Producing Humane Slaughter." Sir James Crichton-Browne will preside. Admission free, without ticket.

A course in infants' diseases, specially arranged for medical officers of welfare centres and others interested in nutritional disorders and dietetics, will be given at the Infants Hospital, Vincent Square, Westminster, from November 26th to December 7th. The fee is £3 3s. The names of qualified practitioners wishing to attend the course (number limited to fifteen) should be sent to the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1, by November 23rd. Cheques should be made payable to the Fellowship. Further courses at the Infants Hospital will be given as follows: April 1st to 13th; September 2nd to 14th; and November 25th to December 7th, 1935.

The Royal Northern Hospital Dining Club will meet at the Café Royal, Regent Street, W., on Friday, November 23rd, at 8.30 p.m. The president, Mr. M. Coleman, will be in the chair, and Lord Horder will be the guest of the club. Tickets, price 10s. 6d., can be obtained from the honorary secretary, Dr. H. A. Cowan, 32, Fitzroy Square, W.1.

The Fellowship of Medicine (1, Wimpole Street, W.) announces that lecture-demonstrations will be given at 11, Chandos Street, W., on November 20th and 27th, at 2.30 p.m.; also on Wednesdays, at 8.30 p.m., in the series on diet and dietetics. Special courses of instruction until the end of the year will be as follows: proctology at St. Mark's Hospital, November 19th to 24th, all day; rheumatism at the British Red Cross Clinic, Tuesdays and Thursdays at 8.30 p.m., November 20th to December 6th; infants' diseases at the Infants Hospital, November 26th to December 8th, afternoons; dermatology at the Blackfriars Skin Hospital, November 26th to December 8th, afternoons; chest diseases (M.R.C.P.) at the Brompton Hospital, Wednesdays and Fridays at 5 p.m., December 12th to January 11th, 1935 (excluding Christmas week). Courses, lectures, etc., arranged by the Fellowship are open only to members and associates.

The issue of *La Medicina Ibero* for October 20th contains a biographical sketch of the late Professor Ramón y Cajal, together with a full-page portrait and a facsimile of his writing a few hours before death.

The November issue of *Tubercle* contains a translation, by Dr. Salvatore Lojacono, of Forlanini's original paper on artificial pneumothorax, which appeared in the *Gazzetta degli Ospedali* in August, 1882.

At the recent congress of the American College of Surgeons held in Boston, honorary fellowships were conferred on Sir Harold Gillies (London), Professor Josef Halban (Vienna), Mr. Harry Platt (Manchester), and Dr. Bethel Solomons (Dublin).

Dr. Sidney Gilford, J.P., has been elected chairman of the Reading Insurance Committee for the ensuing year.

The King has appointed Dr. J. R. Forde to be a Member of the Executive Council of the Gambia and an Official Member of the Legislative Council of that colony.

An Italian Society of Gastro-enterology has been founded at Milan with the Senator Micheli of Turin as president.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and **LETTERS** forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBER** of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, Mediscera Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

White and Brown Sugar

"A. F. S." (Co. Mayo) writes: I have found that many persons who suffer from flatulent dyspepsia, as a consequence of indulging in sweets or ordinary white sugar, can eat with impunity soft brown sugar. I should be obliged if someone would say what is the difference between the two chemically, and also if the more harmless form can be obtained from beet.

Treatment of Ménière's Disease

Dr. ARNOLD S. FERGUSON (Jersey) writes: If it is a case of true Ménière's disease, and not a Ménière symptom-complex, the Zund-Burguet offers great prospects. I have a case now of a farmer sent to me by Dr. Nicolson with true Ménière. After a fortnight's treatment the vertigo has disappeared, and the patient can now climb and prune a tree. I drew attention to this treatment in the *British Medical Journal* of September 10th, 1927 (p. 454). Why not the simple treatment first?

Dr. T. WILSON PARRY (London, N.S) writes: I should be glad to let "Inquirer" have reprints relating to treatment in the above-mentioned "complex of symptoms," which I trust he may find helpful. They include: (1) the case of a hospital nurse (aged 41) who had suffered for five years with typically distressing and prostrating vertiginous attacks. She had been under seven of the best London specialists without obtaining more than temporary relief, but was dramatically cured by the insertion of a seton which was kept *in situ* for six months (vide *Journal*, May 11th, 1907); and (2) the case of a solicitor's clerk (aged 44) who had become prematurely old after suffering for eight years from frequent attacks of the syndrome, which made it impossible for him to follow his profession. He was treated by hypnotic suggestion, and after one treatment, which lasted one and a half minutes (timed), never had another severe attack. This case was followed up by me (*Med. Press*, May 3rd and May 10th, 1908), and two years later (*ibid.*, March 27th, 1907) the patient replied to a letter I had written him telling me that he had had no severe attack since the treatment.

Treatment of Trichophyton Infection

Dr. JAMES HASSON (London, W.2) writes: I feel I must intervene in the discussion on the treatment of trichophyton, and give the result of my experiences. I see about four to five cases weekly of epidermophytosis, and all the classical treatments carried out were a failure in my hands. Most physicians overlook the fact that the disease nests on the nails, and if one treats the palms of the hands and soles of the feet only the disease certainly relapses. The best method is the carbollutecine paint, to which I add 2.5 per cent. of salicylic acid. Rub the nails thoroughly with the

paint twice daily, even after the disease seems to have subsided. Three months' treatment is, in my opinion, a fair period for a rapid cure.

Income Tax

Cessation of Employment

"T. S." ceased to act as an assistant on November 30th, 1933, and was then unemployed until he recently started a new practice. The inspector of taxes claims to revise the assessments for 1932-3 and 1933-4 to put them on the current year's basis. Is this correct?

** Yes. The point is governed by Section 45 (5) of the Finance Act, 1927, which provides that where a person ceases to hold an office or employment the last and penultimate years shall be adjusted to the current year's basis. The penultimate year is at the option of the Revenue—that is, the reverse of the position as regards the second complete year in the case of a person commencing to hold an office or employment.

LETTERS, NOTES, ETC.

Post-anaesthetic Coma

Dr. RACHEL IRWIN (Irish Mission Hospital, Kirin, Manchukuo) writes: A girl, aged 16, was admitted to hospital for excision of tuberculous cervical glands. The left side glands were excised under ether anaesthesia. Gwathmey's method of ether and oil per rectum was used (ether 4 oz., olive oil 1½ oz., with preliminary hypodermic injection of morphine 1/6 grain). Perfect anaesthesia was maintained for over an hour. The patient vomited while the bowel was being washed out, and was fully conscious about four hours later. She made an uninterrupted recovery. Twenty days later the glands on the right side were excised. Exactly the same method of anaesthesia was followed, but the return to consciousness was delayed for about six hours. At the end of that period the patient was conscious for about half an hour, and then relapsed into a comatose state. There was twitching of the arms and periodic attacks of violent restlessness. Pupils dilated, corneal reflex absent. Pulse full and regular. Respiration slow and regular, cheeks blown out. The temperature rose to 104°. Spinal fluid was not under pressure. Systolic blood pressure 110. Repeated irrigation of the bowel revealed no trace of ether, though the breath still smelt of ether twenty-four hours after operation. Glucose and saline were given intravenously and per rectum. After remaining in this condition for fifty-two hours the patient recovered consciousness. There were no further complications.

Routes Out of London

The second edition of the A.A. London Route Map, which is now available (free) to members of the Automobile Association, contains two new features which enhance its value. Colour printing makes the map much easier to read and marginal extensions of the main roads out of London indicate the important centres they serve. With a scale of one inch to the mile the map covers an area twenty miles square between Southgate, Purley, Hounslow, and Barking. Heavy lines indicate the principal exits; and important landmarks, such as war memorials, churches, public buildings, inns, and level crossings, are given in heavy type. Golf courses and county boundaries, new roads under construction and projected, tram-lines, and Ministry of Transport road numbers are clearly marked. Where a choice of routes to the same terminus is shown in the marginal extensions places on the recommended route from Hyde Park Corner are underlined. A footnote gives details of traffic regulations for Waterloo Bridge during the period of reconstruction.

We have received from the Evans Biological Institute, Runcorn, a copy of their brochure entitled *Medical Products of Precision*. An index of therapeutic products offered is classified in relation to the various conditions for which treatment may be required. A full description of each product is given. The booklet is eighty pages in length.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 52, 53, 56, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 260.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, NOVEMBER 24th, 1934

THE CAUSATION AND TREATMENT OF OEDEMA*

BY

T. IZOD BENNETT, M.D., F.R.C.P.

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, MIDDLESEX HOSPITAL, ETC.

The causation of oedema is one of those problems which have given rise to acute controversy in physiological and pathological circles for generations. Even to-day the mechanism is in several ways obscure; the disciples of many opposing schools continue to produce experimental support for their individual theories, and at times controversy is accentuated by the invocation of national patriotism and personal honour.

Oedema is a physical sign indicating an excess of fluid in the tissue spaces. It is met with clinically as a condition calling for treatment chiefly in cases of cardiac failure and of renal disease, and because of the importance of these two conditions it is with them that this opening paper will be principally concerned.

For oedema to be present there must in every case be a greater passage of fluid into the tissue spaces than out of them, and it may be laid down as a primary rule that the problem can only be understood if attention is concentrated on the forces which are in action in the immediate region of the tissue spaces and the walls limiting them, and that the shifting of consideration to other fields such as the kidney, the heart, or other special tissues of the body can only create confusion.

The tissue spaces lie between numbers of living cells, and always contain a certain amount of fluid consisting of water, some crystalloids, and dissolved gases, with at most a very small trace of protein. The blood in the capillaries is separated from the fluid in the tissue spaces only by the extremely thin capillary wall, which permits fluid both to enter the tissue spaces and to return thence to the interior of the capillary. Also lying in immediate proximity to the tissue spaces are the terminations of the lymph channels, formed by completely closed tubes with extremely thin walls, affording little opposition to the passage of fluid. In normal conditions water with dissolved crystalloids and gases passes through the capillary wall into the tissue spaces, and is largely reabsorbed with CO₂ added to it and oxygen and glucose removed, while a certain amount of fluid passes from the tissue spaces into the lymphatics and travels ultimately up the lymphatic system. Blockage in the lymphatic system produces a form of oedema well known in certain pathological conditions but sufficiently rare to be outside the scope of the present discussion.

In order to understand the commonest forms of oedema we must confine our attention to the examination of those forces which regulate the passage of fluid backwards and forwards through the capillary wall, and however complex the problem of oedema may seem it must surely be admitted that these particular forces are now rather fully understood. Only two are of great im-

portance: (1) the intracapillary blood pressure; and (2) the colloid osmotic pressure of the plasma proteins.

It is possible to explain nearly every form of oedema on the assumption that the thin capillary wall acts as semi-permeable membrane permitting the free passage of crystalloids, of which the diffusible ions will arrange themselves on the two sides according to the fundamental laws laid down by Donnan. The intracapillary blood pressure is the great force which propels fluid through the capillary wall into the tissue spaces. This transudation is a natural process of constant occurrence in health. Exact knowledge of the subject is largely due to the work of Krogh, and more recently of Landis and Drinker. Landis has shown that as the blood passes from an arteriole to a venule through a capillary the pressure falls from 27 mm. of mercury to about 13 mm.

If we inquire what conditions can increase the intracapillary pressure and so tend to increase the amount of fluid passing into the tissue spaces, we immediately encounter certain important facts. We find, for example, that in conditions of high blood pressure in the general arterial system—that is, in cases of hypertension and many cases of nephritis—there is no corresponding increase in the capillary pressure, a fact which corresponds with beautiful precision with the well-known fact that hypertension often exists for years without the appearance of oedema. It is, indeed, when hypertension has produced cardiac failure that oedema appears; or again it is in cases of valvular disease of the heart with cardiac failure that we encounter oedema. The explanation appears simple: it is increase in intracapillary pressure coming from the venous end of the capillary which produces oedema in these circumstances. Here we need not necessarily suppose that there is any increased transudation of fluid through the capillary wall; the assumption that the normal return of fluid into the capillary is impeded is sufficient to account for the oedema.

Colloid Osmotic Pressure

We owe to Starling our knowledge of the importance of colloid osmotic pressure. It is nearly forty years since he demonstrated that the presence of proteins in the blood serum is responsible for the osmotic attraction of fluid from the connective tissue spaces back into the capillaries. The term "colloid osmotic pressure" has come into general use, and there is no need at present to enter into discussion of the exact nature of this force, beyond pointing out that it is due partly to the true osmotic pressure of the total colloids and partly to the unequal distribution of diffusible ions, or, in other words, to a Donnan effect.

The colloid osmotic pressure tends to counteract the intracapillary blood pressure, and is a constant drag on the passage of fluid through the capillary wall. At the arterial end of the capillary the blood pressure is sufficient

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

to overcome this, and water and crystalloids pass through, but as one proceeds along the capillary towards its venous end this pressure becomes less and less, and concentration of the colloids leads to a steady increase in the reverse factor of osmosis. In this manner the transudation of fluid is first arrested, and later on there is an actual return flow from the tissue spaces into the capillaries. If for any reason the colloid osmotic pressure falls there will be both an increased tendency for fluid to pass out of the capillary and a greatly lessened force of attraction to drag fluid back from the tissue spaces.

Such a fall in colloid osmotic pressure is brought about if for any reason the proteins in the blood plasma are diminished. This occurs notably in those pathological states in which large amounts of protein escape into the urine. It does not matter whether one is confronted with a heavy albuminuria following acute nephritis, or whether the pathological condition falls into that group which some of us refer to as "nephrosis"; in any such circumstances the colloids of the blood will be diminished, and, albumin being many times more powerful as regards the osmotic pressure of its molecule than is globulin, it will follow that a relative diminution in the albumin of the plasma will have an even greater effect than if there is merely a lowering of the total serum proteins.

The importance in this conception of the role of the plasma proteins in regulating oedema has been recognized following the work of Albert Epstein of New York. It is true that by his experimental work Starling made himself the precursor of Epstein; it is also true that Bright, over a hundred years ago, suggested that albuminuria was the cause of oedema, but to Epstein must be given full credit for the present-day conception. There is still much controversy on this subject, but it is doubtful whether anyone conversant with the work of Krogh, of Govaerts, of E. H. Fishberg, or of Moore and van Slyke can remain sceptical as to the extreme significance of this factor. A number of observers, notably Leiter, Barker, and Kirk, have produced experimental oedema in animals by repeated bleeding followed in each instance by re-injection of the red cells in normal saline in such a manner that great depletion of the plasma proteins, without anaemia, has been produced. Bennett, Dodds, and Robertson were able some years ago to describe a series of cases in which a similar loss of serum proteins had occurred into the peritoneum, the stomach, and elsewhere in men, with oedema formation without evidence of any renal element being involved.

The Capillary Wall and Acute Nephritis

I have not yet referred to the importance of the capillary wall in the production of oedema; this omission has been deliberate. It is true that if the capillary wall is damaged the passage of fluid into the tissue spaces must be rendered easier, but this applies to the passage of fluid in both directions. On the other hand, increased permeability of the capillary wall may lead to loss of protein from the blood plasma, and so to a disturbance of the colloid osmotic balance. It is quite probable that in certain states, among which acute nephritis may be included, this factor is of some importance. Acute nephritis is, by its very nature, a disease which does not frequently come under the observation of any clinician, and writers such as Robert Platt have perhaps over-emphasized those examples of the condition in which extreme oedema has rapidly occurred without (so it is asserted) any appreciable diminution in the plasma proteins.

I can only say that, on the one hand, I have often been impressed by the frequency with which acute nephritis occurs without any appreciable appearance of oedema,

and that, on the other, I retain a vivid memory of the only large group of cases of acute nephritis ever seen by me. This latter group occurred during the war. The patients were healthy men in a battalion of infantry to which I acted as medical officer. In the years 1915 and 1916 there were periods when as many as ten men a day

Diagrams to represent the force regulating the passage of fluid between capillaries and tissue spaces. The blood pressure is represented by arrows within the vessel, plasma proteins are represented as minute globules.

had to be sent away from the front line with acute nephritis. The diagnosis was often made by the late Sergeant Needham, who, during our daily round of the trenches, would observe a man to be puffy under the eyes, and would call him down from the fire-step. On returning to the battalion aid post it would be demonstrated not only that the urine contained albumin, but that it was so full of albumin that, after boiling, the test tube could often be reversed without spilling. I have never seen such cases before or since, and they are quoted now to show that there is at any rate one group of cases of acute nephritis in which an immediate and tremendous loss of protein in the urine occurs.

The problem of the relative importance of the capillary wall in the production of oedema remains obscure. It is probable that in certain types of oedema, and particularly in urticaria, it is of great importance, but it is still more probable that in the two great groups of oedema encountered in cardiac failure and in renal disease the part played by the capillary wall is passive and unimportant.

The Importance of Sodium Chloride

The importance of salt in producing water retention in the tissues has been recognized by the medical profession for thirty years. At the beginning of the present century the late Professor F. Widal drew attention to the manner in which oedema can be influenced by the addition or withdrawal of salt from the diet. To this great physician we owe in large part the revival of interest in the chemical aspects of renal disease. It is, however, somewhat unfortunate that the conception of two functionally different types of pathological kidney—the one retaining nitrogenous substances and the other retaining salt and water—should have resulted from the researches of his followers, and become widespread. Not one, but a series of papers would have to be given in order to review all the work that has been done on this subject. Here it can only be said that the theory that nephritis creates a barrier to the passage of salt through the nephrons is no longer tenable.

But it remains true that salt is provocative of oedema through some property of holding water in the tissues. It must be borne in mind that salt possesses this property in cases of cardiac as well as of renal oedema, and it must further be borne in mind that the work of the late L. Blum has demonstrated that it is the sodium and not the chlorine ion which chiefly possesses this property.

Treatment of Oedema

The oedemas of cardiac and of renal origin are of such importance that it is not proposed to deal with the treatment of other types. Apart from cases in which there is local obstruction to a vein by thrombosis, adhesions, or pressure, right-sided heart failure provides the purest example of oedema due to increased pressure at the venous end of the capillaries. The regularity with which the relief of cardiac failure is followed by the disappearance of oedema is in itself very strong indirect evidence in favour of the theoretical considerations which have just been discussed.

Considering, in the first place, oedema of purely cardiac origin, we must recognize that a generalized oedema arising in this manner implies failure of the right side of the heart, and that this may occur with valvular disease, with a myocarditis of infective origin, or as the result of prolonged hypertension. Without discussing these groups individually, it may be said that any factor which diminishes the output of the right heart will necessarily tend to create congestion in the systemic venous circulation, and, conversely, it may be said that any treatment which tends to improve the output of the right ventricle

will tend to lead to an amelioration of such cardiac oedema. For these reasons prolonged rest is essential, and when factors such as auricular fibrillation are present digitalis is usually very valuable. Digitalis, of course, finds its most important indication in conditions of auricular fibrillation with right-sided cardiac failure, and in recent years many of us have found that the drug can most easily and effectively be given in the form of the powdered leaf. The one-grain pills of this preparation retain their potency even when kept for a long time, and make a very convenient medium for administration. When using this preparation one is relieved of anxiety as to the potency, as to the possibility of the drug being destroyed by other substances given with it, and of the danger of faulty measurement. It is usual to give at the outset from 6 to 10 grains to a patient of average size, and to reduce this gradually as the digitalis effect becomes evident.

In all cases of generalized oedema successful treatment demands a careful record of progress from day to day. It is very important to be able to judge at any time whether the oedema is waxing or waning. This can be accomplished either by the accurate weighing of the patient or by an accurate record of the water balance. Patients are often so ill, and good weighing apparatus is so expensive, that the former course is scarcely practicable; but estimation of the water balance is a relatively simple procedure, which should be carried out in all cases, both in private and in hospital. It is only necessary for the nurse or relative in charge of the case to keep an exact record of the amount of fluid taken by the patient, and to measure the volume of urine passed. The patient should be asked to pass urine just before the beginning of each official day—say at 8.30 a.m.—and this should be added to the urine of the previous day. It is well to place every patient on a fixed daily intake of fluid, which must include all fluids with the necessary allowance for the water contained in fruit, ice-cream, etc. A limit of 30 oz. daily can be imposed with no hardship; in severe cases of oedema this may be cut down to 25 oz., or even to 20 oz.; restriction below this point can only be obtained at the cost of considerable discomfort.

The next point of importance in the treatment of most generalized oedemas is that a salt-free diet should be imposed; salt must be forbidden at all meals, and the salt used in cooking must be eliminated. Bread is sometimes a difficulty, because ordinary baker's bread contains appreciable quantities of salt. Salt-free unleavened bread can now be readily obtained from Jewish caterers. The imposition of a salt-free diet implies a regime calling for considerable ingenuity if the diet is not to be unpalatable; the use of lemon juice and of sodium-free salt is a considerable help.

The Mercurial Diuretics

Reverting to the treatment of the oedema of cardiac failure: a salt-free diet having been imposed, the water balance correctly determined, and digitalis therapy pushed to the limits of its utility, it frequently happens that cardiac dropsy persists. A certain degree of improvement has been achieved, but the patient remains partially waterlogged. In such cases the new mercurial diuretics are often of great value. It is no exaggeration to say that these substances represent the greatest advance in the treatment of cardiac failure by drugs since the introduction of digitalis. It has been argued that to remove water from the tissues of a patient does nothing to improve his myocardium; it is very doubtful whether there is even academic justification for such a statement, but even if it were so no patient would hesitate to choose between lying in bed waterlogged with oedema and leading the life of an invalid who is able to get about a little and is free from superfluous water.

It is unnecessary here to enter into the mode of action of these diuretics, beyond saying that there is strong evidence to show that their main action is a direct stimulation of the kidney to secrete more urine, that there is no evidence as to any harmful cardiac effect, and that, in ordinary dosage, the renal effect is not dangerous. There were so many unfavourable reports concerning novasurol that numbers of clinicians were discouraged at the outset, and its use was largely abandoned. Concerning salyrgan experience tells a different tale. There are very few contraindications to its use, and it seems to be extremely safe. Its effect is enhanced when it is given in conjunction with ammonium chloride, 15 grains of which should be prescribed thrice daily for forty-eight hours previous to the injection, by the intravenous or intramuscular route, of 0.5 to 2 c.cm. of salyrgan.

A typical result is shown in the accompanying chart, which was obtained from a patient admitted to the

Middlesex Hospital suffering from severe hypertensive cardiac failure with anasarca. Digitalis had been pushed for many weeks in the patient's home, but he remained completely bed-ridden and helpless. On admission he was placed on a salt-free diet, and fluids were restricted to 30 oz. daily. Ammonium chloride was administered, and after three days the first intravenous injection of salyrgan was given, and the chart shows how this and subsequent injections produced responses varying

from 50 to 180 oz. of urine. The net result was that within three weeks over 50 pints of superfluous fluid had been removed from this patient, who was able to return home infinitely better than before.

Before leaving the subject of cardiac failure a word must be said concerning a somewhat rare but very important form of oedema—namely, the acute pulmonary oedema encountered in sudden left-sided ventricular failure. In cases of hypertension the hypertrophied heart will not infrequently, after years of favourable effort, suddenly give way. Such sudden cardiac collapse often manifests itself by pure left ventricular failure, a clinical syndrome characterized by attacks of cardiac asthma with paroxysms of dyspnoea often occurring at night, by dilatation of the left ventricle, and by the appearance of moist sounds at the bases of the lungs. In extreme cases there may be copious expectoration of pink, frothy sputum, and dyspnoea is often of extreme violence and terribly alarming to the patient and those around him. The recognition and treatment of such cases is important. Morphine and venesection are the sovereign remedies, the immediate application of which has often saved life in what is one of the most important medical emergencies occurring in general practice. It was recently my experience to see this condition in a patient in whom generalized vascular disease had produced thrombosis of many of the peripheral veins to such an extent that venesection was very difficult.

We were able, however, to open a vein after dissection, and the removal of 15 oz. of blood, together with the administration of morphine 1/4 grain, so revived the patient that he was able next day to describe a previous attack which had occurred during a cruise. On that occasion the ship's doctor had been unable to find the median basilic vein, but had pursued his efforts until he reached the artery. The patient was landed at the nearest port on the following day with a tourniquet round his arm, and made a good recovery, although to this day he is able to puzzle physicians who cannot find his radial pulse.

Renal Oedema

At least two, and probably three, varieties must be included under the heading of renal oedema. First it must be recognized that cases of chronic nephritis associated with high blood pressure often exhibit cardiac failure at the termination, and that this group sometimes

presents great difficulties of exact diagnosis and classification. Cardiac hypertrophy is usually present, but the systolic blood pressure may have fallen sufficiently to confuse matters, although the diastolic pressure is generally maintained at an abnormally high level. There is some albuminuria, but it may be impossible to decide whether this is the result of renal changes, or whether it is merely the slight albuminuria which accompanies the disordered renal circulation of

CHART 1.—Effect of salyrgan on urinary output in cardiac failure with oedema. Fluid intake 30 oz. daily; 1 to 2 c.cm. of salyrgan given intravenously on days marked "S"; urinary output in ounces indicated by vertical columns; total diminution in pints of body fluid during treatment indicated by curve.

cardiac failure. It must be noted that actual renal failure tends to diminish rather than to increase oedema, because polyuria is one of the earliest and most striking effects of declining renal function, and will tend to drain off superfluous water from the tissues. In chronic nephritis with high blood pressure oedema is not infrequently of complex origin, being partly cardiac and partly renal.

True renal oedema is seen in the condition sometimes described as "nephrosis," and in those cases of undoubted nephritis characterized by what is sometimes known as "the nephrotic syndrome." In such cases there is long-standing albuminuria of considerable degree, with the result that the plasma proteins are greatly reduced and oedema appears. It would be out of place here to discuss at any length the conception of nephrosis, beyond saying that this envisages a group of patients in whom there is no rise of blood pressure, no change in the retinae, no history of haematuria, no nitrogen retention, no impaired renal function, nor any objective sign of disease of the kidneys beyond albuminuria, that this group exhibits lowering of the protein content of the blood, particularly as regards the albumin fraction, and that this diminution leads many of them to develop oedema. It is believed that these patients live for years, that many of them recover completely, that, if they die, it is usually from pneumococcal peritonitis or from some other generalized infection, and that the kidneys, when examined, show

glomeruli which are practically normal, with convoluted tubules exhibiting degenerative changes.

The original conception of Epstein, that these cases were not of primary renal origin, but represented some disorder of metabolism, has not been confirmed, and although it still remains impossible in many cases to demonstrate a glomerular lesion the general opinion to-day is that the albuminuria in nephrosis must represent an increased permeability, and so an abnormality of the glomeruli. On the other hand, the fundamental conception of Epstein that the oedema of these cases is the direct result of the leakage of albumin from the blood plasma has become more and more firmly established. As regards prognosis the problem remains most difficult; all of us who have had much experience have seen some of these patients, after a long course in which albuminuria and oedema were the sole manifestations, suddenly begin to develop hypertension and proceed to a uraemic termination. We do not know whether the cases were misdiagnosed as nephrosis at the outset and were really extremely subacute cases of glomerular nephritis, or whether, as believed by Volhard and Fahr, it is possible for chronic nephrosis to proceed to a condition in which there is sclerosis of the kidney. In this connexion it is notable that A. M. Fishberg, in his latest work, states that he has never seen an example of nephrotic contracted kidney.

Nephrosis

Nephrosis is, in my experience, a rare disease. In collaboration with Professor E. C. Dodds I have been able to publish a description of several cases, together with post-mortem findings described by Professor S. L. Baker. My clinical experience includes two cases which have been under my observation for from three to five years, in one of which albuminuria has now been present for over six years, and in the other for over fifteen. Details of these cases are set out in the accompanying tables, from which it will be seen that there is no nitrogen retention in either

case, and that otherwise their chemistry exhibits the hypercholesterolaemia, the lowered calcium, and the decrease in plasma proteins characteristic of nephrosis. In the more chronic case there has never been any suggestion of hypertension, but in the shorter case the blood pressure figures have during later years been somewhat disquieting. At the same time this patient remains in apparently perfect health; he came to me showing nothing except a profuse albuminuria, which led to a progressive fall in the plasma proteins and ultimately to the appearance of oedema. The institution of a rigid salt-free diet and a cure of dechlorination at Evian cleared up the oedema. He has followed a salt-free diet for three years now, and when seen a few months ago was in excellent health, with only a persistent trace of albumin in the urine, and with plasma proteins which have returned almost to normal.

The other patient has been troubled with chronic oedema, waxing and waning in intensity for fifteen years. Albuminuria is always considerable, and the plasma proteins are continuously very low, the globulin figure being actually in excess of that for albumin. But she is able, by persisting with a salt-free diet, and with the occasional use of diuretics, to keep well enough to lead an ordinary sedentary life. Two years ago the oedema became much more severe in spite of these precautions. The administration of urea failed to relieve it. On my advice her doctor gave her several intravenous injections of salyrgan, with the result that the oedema completely disappeared, and she has remained practically free from it since.

Treatment of Nephrosis and Nephrotic Syndrome

The treatment of renal oedema in cases of nephrosis and of the nephrotic syndrome should aim at the removal of the increased permeability of the glomerular epithelium and replacement of the diminished plasma proteins. Unfortunately, we have no means of achieving either of these ends, although it is interesting to note that Hartmann, Senn, Nelson, and Perley have succeeded in removing the oedema in certain cases of nephrosis by repeated intravenous injections of strong solutions of gum acacia. On the other hand, the diet originally advocated by Epstein, which contains abundant proteins, especially those of vegetable origin, is strongly indicated in these cases, because not only is it necessary to supply sufficient material from which the body may produce new serum-albumin, but the absence of any tendency towards nitrogen retention makes it permissible to supply the blood with sufficient amino-acids to create the full quota of urea to act as a diuretic. A salt-free diet is essential, and the water intake should be limited to a figure compatible with comfort. Mild diuretics are desirable, and among these urea occupies an important place, and may be given either in capsules or dissolved in small quantities of lemonade during periods of increasing oedema. Thyroid extract has often been advocated, but my personal experience in this respect has been discouraging. Salyrgan is certainly of the utmost value whenever it is necessary to reduce oedema of crippling degree. It must never be forgotten that extensive oedema carries with it the constant risk of infection; anyone who has had the experience of seeing a patient suddenly develop pneumococcal peritonitis or a spreading cellulitis will understand the importance of reducing nephrotic oedema whenever it becomes extensive. If this cannot be done with salyrgan or by other medical means it may be necessary to resort to the use of Southey's tubes or to drain the oedema by incision over the malleoli.

Treatment of Acute and Subacute Glomerular Nephritis

Treatment in glomerular nephritis must be very different from that of nephrosis and the nephrotic syndrome. In acute cases the utmost possible degree of glomerular rest

must be sought for. The cause of the oedema is somewhat obscure; not only may it be a combination of increased intracapillary pressure and of lowered colloid osmotic pressure, but such factors as increased permeability of the capillary wall cannot be eliminated. Renal function is usually greatly disturbed, and there is nitrogen retention or great loss of the concentrating power of the kidney. In these cases the water intake must be carefully controlled, and the diet must not only be salt-free, but the treatment must consist of virtual starvation for as long a period as can be maintained without risk to the patient.

CHART II.—Blood analysis to show effect of starvation on blood urea in a case of acute nephritis.

The above diagram illustrates the effect of such treatment on a girl of 19, who was admitted to the Middlesex Hospital last December. On admission there was slight oedema in the form of puffiness below the eyes, and a considerable masked oedema manifested by an increase in weight of nearly a stone. The blood urea was over 200 mg., and the urinary output during the first week was below 10 oz. daily. Living on a water intake not exceeding 20 oz. and food limited to half an apple or some tiny pieces of orange daily, the blood urea was seen to fall rapidly to a very low level, and at the present time the patient appears perfectly normal, except that a trace of albumin is occasionally to be found in the urine.

The treatment of subacute and chronic nephritis with oedema is a matter of great difficulty. If cardiovascular change is minimal the therapeutic indications are closely similar to those in nephrosis; if, on the other hand, haematuria is recurrent and evidence of impairment of renal function marked, treatment must be directed towards these rather than towards the actual oedema. It would be out of place to discuss this further here, beyond emphasizing that oedema becomes a minor manifestation in such serious cases as these.

It cannot be laid down too strongly that, on the one hand, the syndrome to which the term "nephrosis" may properly be given demands treatment with a diet generous in protein, and that substances such as urea and salyrgan are not contraindicated in these circumstances; while, on the other hand, cases of undoubted nephritis with evidence of hypertension and impairment of renal function call for the greatest caution in the choice of the protein ration, require the avoidance of drugs which might stimulate the damaged kidney, and demand treatment calculated to remove infection and promote rest rather than merely to relieve oedema.

Summary

Oedema is a physical sign indicating an excess of fluid in the tissue spaces. Two great factors are chiefly responsible for the occurrence of oedema: (a) changes in the intracapillary blood pressure; and (b) lowering of the colloid osmotic pressure of the plasma proteins.

Increased permeability of the capillary wall is probably important in the production of oedema of the urticarial type; it is of possible importance in cases of acute nephritis. Sodium chloride is not a causal factor in the production of oedema, but is provocative of the condition, in that it tends to hold water in the tissue spaces rather than in the circulation; the sodium and not the chlorine ion is responsible.

As regards treatment, cardiac oedema demands prolonged rest, digitalis therapy in appropriate cases, a salt-free diet, and the employment of mercurial diuretics in resistant cases. In these, as in all cases of oedema, accurate record of the water balance is important. Acute pulmonary oedema tends to occur in cases of left-sided cardiac failure, and is an indication for venesection and the administration of morphine.

Renal oedema includes two and possibly three varieties: (a) the type seen in terminal cases of nephritis with hypertension; (b) the type seen in cases of "nephrosis" and the "nephrotic syndrome"; and (c) the type seen in cases of acute nephritis. The oedema of nephrosis and the nephrotic syndrome is due to loss of protein from the blood plasma, and calls for a diet which is salt-free and relatively rich in protein. Mercurial diuretics are not contraindicated in resistant cases. The oedema of glomerular nephritis requires very cautious treatment. In the acute phase virtual starvation is necessary; in chronic cases careful judgement is required for the accurate regulation of the protein in the diet, and the avoidance of anything that may further damage the kidney.

I am greatly indebted to Professor E. C. Dodds and to the staff of the Courtauld Institute of Biochemistry for many of the chemical analyses quoted in this paper.

The number of suicides in Germany in 1932 numbered 18,934, or 29.2 per 100,000 inhabitants, as compared with 28.8 in 1931, 23.3 in 1913, and 21.2 in 1891, when the German statistics for suicides were first compiled. The number of suicides per 100,000 inhabitants in 1932 was 41.6 for males and 17.4 for females, as compared with 35 for males and 11.7 for females in 1913. The most frequent form of suicide was hanging, which was noted in 42.7 per cent. of the cases. Next, after a long interval, came poisoning by gas (15.9 per cent.), shooting (13.2 per cent.), drowning (11.6 per cent.), other forms of poisoning (7.1 per cent.), and other causes (under 10 per cent.).

CHRONIC CERVICITIS: ITS INFLUENCE ON THE URINARY TRACT AND ITS TREATMENT BY THE DIATHERMY CUTTING CURRENT CURETTE*

BY

J. C. AINSWORTH-DAVIS, M.A., M.D.CAMB.,
F.R.C.S.ENG.

UROLOGICAL SURGEON, ROYAL WATERLOO HOSPITAL, LONDON

For the past eighteen months my attention has been more and more drawn to the fact that chronic cervicitis is responsible for certain diseases of the urinary tract the aetiology of which in the past has been only imperfectly understood. This conclusion is supported partly by clinical observation, partly by experimental evidence, and mainly by the results which have followed operative treatment of this focus of infection.

Any urological out-patient department is overcrowded with women whose chief symptoms are frequency, dysuria, pain in one or both loins, and varying degrees of backache, and with a history usually of having borne one or more children. Many are referred from the gynae-

FIG. 1.

logical department with a note: "Will the urologist please see and treat." Examination may reveal some urinary cause of the condition, such as cystocele, a stone in the bladder, or tuberculous kidney, but in the majority of cases no such abnormality can be discovered, the cystoscopic appearances being those of mild trigonitis, as shown by redness, swelling, and often pseudo-membranous patches on the trigone. Fig. 1 is a composite view of the bladder floor showing pseudo-membranous trigonitis. There is, as a rule, an associated chronic urethritis, the urethra being more tender than usual to the passage of an instrument, and if stretched with a straight Kollmann's dilator will not tolerate an expansion of more than about 25 degrees Charrière, as compared with the normal of 35 degrees.

The changes in the upper urinary tract are seen by intravenous pyelography, which may demonstrate some degree of dilatation of the renal pelvis and upper inch or two of the ureter, and, in neglected cases, kinking of the pelvi-ureteral junction, due to inflammatory adhesions between the renal pelvis and ureter, and a varying degree of hydronephrosis from the increasing urinary obstruction. The urine is usually sterile, but may contain pus cells and *B. coli*, in which case renal specimens are collected by ureteric catheterization. Almost invariably, however, these are normal, which proves that the kidneys are not the source of the bladder infection.

The Association of Urological Inflammation with Genital Infection

The most significant thing in the majority of these women is the evidence of some degree of genital infection as shown by chronic cervicitis or cervical erosion, with or without some laceration of the cervix, and often by tenderness and thickening in the fornices. This association of genital and urological inflammations is so constant that one has almost been able to predict from the cystoscopic findings what the cervix would look like when viewed through a speculum; thus much suspicion has come to fall on this structure, and with it a desire to know more about its habits and their consequences.

This led some two years ago to a series of animal experiments carried out by Winsbury-White, and described by him in his Hunterian Lecture in February, 1933, under the heading of "The Spread of Infection from the Uterine Cervix to the Urinary Tract, and the Ascent of Infection from the Lower Urinary Tract to the Kidneys." Briefly they consisted of the injection of Indian ink or tubercle bacilli into the cervixes of rabbits, rats, and guinea-pigs, and in killing the animals at periods of time varying from one hour to three weeks later. The pelvic organs and the soft parts of the posterior pelvic and abdominal walls were then sectioned in a serial manner and examined microscopically.

The Spread of Infection

Perivascular lymphatic spread was demonstrated both forward to the submucous coat of the trigone of the bladder and upward to the kidney by way of the base of the broad ligament, the hollow of the sacrum, the brim of the pelvis in the region of the common iliac vessels, the glands and lymph vessels of the renal hilum, and, finally, by invasion of the renal substance through the fibro-fatty tissue surrounding the calyces. That the invasion was not haematogenous was proved by the absence of pigment or inflammation in the glomeruli and capillaries of the renal cortex which is characteristic of a blood-borne infection. That it did not spread up the walls of the ureters was shown by the complete absence of pigment in all sections made through them at successive levels. Winsbury-White considers that this ascending spread is supported by the clinical facts which are so constantly observed and which include tenderness in the fornices and backache, and by x-ray examination, which shows phleboliths on the pelvic floor and calcified glands along the posterior abdominal wall.

These experiments and the fact that frequency and dysuria in women are often very resistant to treatment, if this be directed solely to the urinary tract, emphasize the importance of visual inspection of the cervix and careful bimanual examination of the uterus and adnexa in the investigation of patients with urological symptoms. That they should be resistant to treatment becomes simple to explain when often no attempt is made to deal adequately with a cervicitis the significance of which has not been realized.

Frankl of Vienna has shown that the area of infection is not only the cervical canal, but also that part of the endometrium lying immediately above the internal os and known as the pars intermedia. Dr. Knott of Guy's Hospital, by sectioning a series of cervixes removed by amputation by Mr. Lyle Cameron at the Royal Waterloo Hospital, has shown that the cervical glands, as a result of chronic inflammation, penetrate to a depth which rarely exceeds one-eighth of an inch. The complete cure of the condition, therefore, necessitates the removal of the lining membrane of the cervical canal and pars intermedia and all the subjacent glands.

*Read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

Amputation or Cauterization of Cervix in Treatment

The methods of treatment which have been employed for chronic cervicitis are many and various. The non-surgical procedures, such as douches, local applications, tampons, ionization, ultra-violet light, and medical diathermy, are, on the whole, disappointing, and are usually followed by an early relapse when discontinued. Surgical methods are much more reliable, and the two procedures commonly employed are amputation of the cervix and dilatation of the cervix followed by cautery. In my opinion neither of these is satisfactory. Complete

FIG. 2.—Diathermy cutting current curette.

amputation, if skilfully performed, will certainly remove the infected tissues, but this operation is not to be recommended in nulliparae or in younger women who are anxious to bear more children. Dilatation followed by cautery is a popular method, and although the whole of the affected area can be treated, the deep-seated glands are not completely destroyed, there is frequently but slight improvement of the local condition, and the treatment often has to be repeated. A number of women in whom hysterectomy was advised for other reasons were submitted either to partial amputation of the cervix or to dilatation and cauterization of the cervix before the uterus was removed. Microscopical examination showed

On the principle of the McCarthy cutting loop for the removal of fibrous prostates through a cystoscope, and by means of which longitudinal strips of the gland can be resected, Mr. Schranz of the Genito-Urinary Company has made for me a series of cutting current curettes of various sizes. They consist of a fine tungsten wire loop, elliptical in shape and fixed at an angle of 30 degrees at one end of a well-insulated metal rod. The other end of this rod is threaded, and screws into a larger rod about four and a half inches long, which engages in a socket fixed at a right angle on an insulated handle in such a

FIG. 3.—Method of using the cervical curette.

way that it can rotate but not disengage without a strong pull. The insulation of the rod is increased near the handle to form a collar, serrated at the circumference, by which it can easily be rotated with the thumb and index finger of the right hand. The cable from the cutting diathermy machine plugs on to the pin at the lower end of the handle (Fig. 2).

The patient, who should arrange to stay in a hospital or nursing home for a week, is anaesthetized and placed in the lithotomy position. A lead belt surrounding the waist is connected to the diathermy machine and constitutes the indifferent electrode. The skin and vagina are painted with surgical dettol, which is non-inflam-

FIG. 4.

FIG. 5.

FIG. 6.

that in both methods much infected glandular tissue was left behind, which explains the relapses that may follow these operations.

The Diathermy Cutting Current Curette

In my opinion the ideal way of complying with the essentials of treatment is to remove the glandular tissues completely by means of a wire loop activated by the diathermy cutting current. The method was, I believe, first introduced by Everard Williams, and a loop made for him which he called the "coniser." I have used this loop, but have not been satisfied with its results.

mable, towels are adjusted, a speculum inserted, the cervix grasped laterally with vulsellum forceps and pulled forward. The uterine cavity is explored with a sound, the cervical canal dilated to No. 8 Hegar (25 degrees Charrière), and dried as far as possible with gauze.

The strength of the current is adjusted (dial setting 4 on the genito-urinary endodiathermy machine), and the curette passed a quarter of an inch beyond the internal os (Fig. 3). The current is then turned on with the foot-switch, and a strip of pars intermedia and cervix removed from the roof of the canal, the instrument being steadied with the fingers of the left hand. Great

care must be taken not to allow the cutting loop to slip as it leaves the external os, and to remember at this point to turn off the current with the foot-switch; also to hold the stem of the curette parallel with the cervical canal in order not to cut too deeply. The loop is so constructed that strips of lining membrane and underlying glands are removed in one piece if the instrument is correctly held. If for any reason it is necessary to make a deeper cut, the instrument can be tilted and tissue up to one-quarter of an inch in depth cut out. Strips are then cut from the sides, and lastly the floor. As each cut is made bleeding automatically stops from this area, until finally the endocervix is completely dry, which enables the operator to gain a perfect view and to deal with any small part which may have escaped resection. If an erosion is present it is excised by a larger cutting loop mounted on a bakelite handle, and the uterine cavity and cervical canal packed with gauze plugging soaked in 10 per cent. picric acid in absolute alcohol, which is removed eight hours later. The operation is completed by dilating up the urethra with a special pair of urethral forceps to 40 degrees Charrière in order to deal with the associated urethritis.

Saline douches are begun fourteen days later, and continued until the cervix is healed, which takes about two months. Intermittent dilatations of the urethra at fortnightly intervals are continued until a calibre of 40 degrees Charrière is attained without bleeding and without any appreciable resistance.

Figs. 4, 5, and 6 show a chronic cervicitis with an extensive erosion before treatment, directly after treatment, and three months after treatment. The results of this method of operative treatment for chronic cervicitis, especially if it has given rise to renal or vesical symptoms, I have found to be excellent, both clinically and pathologically.

Clinically the vaginal discharge, frequency, dysuria, renal pain, and backache disappear in the absence of any other gynaecological or urological cause, and in a series of eighty cases which have been followed up by Dr. Bryce Cooper and myself, both at the Royal Waterloo Hospital and in private, there was no distortion or contraction of the cervical canal. This was only to be expected, as excision of tissue by the diathermy cutting current is followed by a supple scar, which does not contract, and so resembles the results obtained in other parts of the body. Sufficient time has not elapsed for me to give an opinion on the effect that this treatment may have on conception and future pregnancy, but in one case in the series conception took place for the first time after twelve years of married life, and resulted in a normal pregnancy.

Pathologically a series of hysterectomies was performed by Mr. Lyle Cameron, in some cases immediately following the diathermy curette and in some six months later. By serial sections of the cervix Dr. Knott showed in the former that all the infected tissues had been removed, and in the latter that there were no signs of cervicitis.

In 1933 the British Science Guild began the Research and Development Lectures with the object of directing public attention to the importance of scientific research and of the utilization of its results in the service of mankind. Early in 1934 a proposal was made that the lectures should be given in the theatre of the Royal Institution, where special equipment and facilities exist for experiments and demonstrations, and arrangements were made by which the Guild had the use of the theatre on two occasions in May. Four further lectures have now been arranged, including one, on December 12th, at 9 p.m., by Dr. G. W. C. Kaye, on "Sound and Noise."

GAS GANGRENE RESTRICTED TO THE SUBCUTANEOUS TISSUES

REPORT ON A CASE

BY

MARGARET MOORE WHITE, M.B., F.R.C.S.

RESIDENT SURGICAL OFFICER, WEST NORFOLK AND KING'S LYNN GENERAL HOSPITAL

The following case is thought to be of sufficient interest to report on account of: (1) the limitation of the infection to the subcutaneous tissues of one limb; (2) the good general condition of the child, maintained until pyogenic organisms made their appearance; and (3) the uneventful recovery, whether due to the mild pathogenicity of the organisms or as a response to serum.

Case Record

A small boy, aged 7; ran a nail into the right leg, just below the knee, on February 10th, 1934. This was shortly afterwards withdrawn by his father. He was sent into hospital on February 14th as a case of cellulitis of the leg. On admission his temperature was 99.2°, and pulse 100. He did not look ill or toxic, nor did he seem in any great pain, but on questioning he said: "I'm all right in myself, but my leg hurts me."

On examination the entire right lower limb was very swollen, tense, of a whitish colour, and there was a very small perforating wound over the external tibial condyle above the site of origin of the anterior tibial group of muscles. There was no pitting or crepitus; the oedema was solid. The circumference of the thigh was 15½ inches, as compared with 12 inches on the left side. An anaesthetic was given, and on cleaning the wound preparatory to excision of the skin edges a few bubbles of gas and a small quantity of pus issued from it. The surrounding tissues were gently pressed, and a few more bubbles and thin, brownish serum appeared. A smear was taken, the edges of the wound excised, and the latter left open.

An immediate examination of the pus was made, and, on finding organisms typical of the *B. welchii* group, anti-gas-gangrene serum was given, 5,000 units intravenously and 5,000 intramuscularly. Hot fomentations were applied to the wound, and the leg placed on a back splint. The child's general condition remained good, and the condition of the limb unchanged, the oedema not extending above Poupart's ligament. An x-ray photograph showed gas bubbles subcutaneously only in the region of the knee. A further 10,000 units of serum was given on February 15th into the subcutaneous tissues of the right thigh, and 5,000 intravenously with 5,000 intramuscularly on February 17th.

Up to February 28th the circumference of the thigh had diminished by one inch, the child was well and comfortable, and there continued to be a small sero-purulent discharge from the wound; but on March 1st his temperature and pulse began to rise, and he complained of increasing pain on the inner side of the thigh. An inflamed indurated area was present along the inner side of the lower third of the thigh, which was very tender. Slight pitting oedema of the scrotum developed at this stage, but soon disappeared. On March 2nd an incision was made into the subcutaneous tissues along the inner side of the thigh and a small quantity of pus obtained, which was sent for pathological examination, the report being haemolytic streptococci only. Following this incision quantities of serum drained from the wound. Further incisions were made into the subcutaneous tissues in the now indurated areas in the popliteal region and inner side of the upper part of the leg on March 5th and 9th, and the small quantity of pus which was first obtained was soon followed by the discharge of large quantities of serum. Hot fomentations were applied and, later, eusol dressings. During the period of pyogenic infection the child had a raised temperature and pulse, but these became normal on March 14th, and he was discharged on the 19th. The limb was now 1½ inch less in circum-

ference round the thigh than the other, the incisions were granulating in healthily, and the movements of the limb normal. On recent inquiry from his doctor it was learnt that the wounds soon healed, and the child has since remained perfectly well.

Remarks

On reviewing the literature on this subject I can

find no statistics to show in what proportion of cases infection is confined to the subcutaneous tissues as above, but Choyce¹ mentions that it does occur. Thirty cases, however, have been reported of gas-gangrene infection following subcutaneous injections,^{2,3,4,5} either given hypodermically or as subcutaneous salines, but in the majority of these cases the infection became rapidly generalized and death ensued, or the patients recovered only after immediate multiple incisions and the administration of serum.

Perhaps Tissier's findings⁶ may explain the mildness of the infection. Tissier, in an article written in 1916, described experiments to show that gas-forming organisms in themselves had little power to cause gas gangrene, but when in association with other organisms they rapidly produced the typical disease. He showed that filtered cultures of *B. welchii* or *B. oedematiens* produced no effects; inoculation of animals with either of these organisms alone produced a hard oedema, which slowly disappeared, but when there was added to these cultures growths of aerobic bacteria the effects of malignant oedema were noted. He also stated that the presence of devitalized tissue was the necessary condition for the development of gas infection.

On looking at this boy's temperature chart it will be seen that the onset of severe symptoms coincided with the first appearance of pyogenic organisms in the pus. Up to this time on three occasions anaerobic organisms only were obtained from the wound, but on the twentieth day after infection the pus obtained on incision over the indurated area on the thigh gave a growth of haemolytic streptococci, and at this time the child's general condition was not so good. The hard, solid oedema of the leg, with absence of crepitus, suggested that the infection was mainly by organisms of the *B. oedematiens* type, although both groups of organisms were demonstrated in the pus.

It is also interesting to note in the cases quoted that the patients who received their infections by subcutaneous methods were in hospital suffering from some pre-existent disease or from loss of blood, and that other patients in better condition, who were given injections at the same time with the infected agent, did not develop gas gangrene.⁷ It seems strange in this case that, in the absence of devitalized tissue in a healthy child, gas gangrene should have developed at all, and it should be noted that at no time was there any evidence of infection extending beneath the deep fascia. How much of the child's good recovery was due to the early administration of serum or how much to the low pathogenicity of the organisms it is difficult to say.

In another case admitted to this hospital a few months ago, of severe compound fracture of the leg with much destruction of muscle, gas gangrene set in on the third day, although 12,000 units of anti-gas-gangrene serum had been given as a prophylactic dose on admission. It quickly subsided, however, following intravenous administration of large doses of

serum and free opening up of the wound. A reappearance of gas infection of the leg on the forty-fifth day after the injury followed encasement in plaster, but subsided again after serum injection and exposure of the wound to the air.

My thanks are due to Mr. Lewin for permission to publish this case, and to Dr. Knott of Guy's Hospital, who kindly confirmed the pathological findings.

IV = Intravenous. IM = Intramuscular. SC = Subcutaneous.

INTERFERENCE IN THE SCHICK TEST BY DIPHTHERIA ANTITOXIN INJECTION IN THE HUMAN SUBJECT

BY

R. B. MAYFIELD, M.B., B.Ch.CAMB., D.P.H.LOND.
LATE ASSISTANT MEDICAL OFFICER, NORTH-WESTERN HOSPITAL,
HAMPSHIRE; ASSISTANT MEDICAL OFFICER OF HEALTH,
PLYMOUTH

The aim of this investigation was to find out how soon an injection of antidiphtheritic serum may be given to a suspected case of diphtheria after the performance of a Schick test without invalidating the result of that test.

Ker¹ (1924), in his presidential address to the Fever Hospital Group of the Society of Medical Officers of Health, gave an account of some work on this point. He assumed that all definite cases of diphtheria are Schick-positive at the onset of the disease, and, by testing such cases at varying intervals before the intramuscular injection of antidiphtheritic serum, he tried to find out how soon the serum had to be administered after the performance of the test in order to inhibit the positive reaction. He tested forty-seven cases two hours before the injection of serum, and of these forty-five yielded positive reactions and two were doubtful. Of nineteen cases tested one hour before the injection of serum, eighteen gave positive reactions and one a negative. The single patient reacting negatively died of circulatory failure within ten days after the test was performed, and it is possible that the circulation was already too depressed to respond to the stimulus of the test. Finally, fifty-six cases were tested immediately before the injection of serum, and of these forty-five had positive reactions, two were doubtful, and nine

were negative. He suggested various possible explanations as to why these nine cases reacted negatively. Two, for instance, were doubtful cases clinically, and in four there was some question as to the reliability of the test toxin. Nevertheless, nine out of fifty-six seems too high a proportion to be disregarded. Ker also reported results of seven Schick tests on cases of diphtheria immediately before the intravenous injection of antitoxin. Two of these reacted positively, four negatively, and one was doubtful.

Glenny and Hopkins² (1925) carried out similar tests on guinea-pigs. They found that the inhibition or reduction in size of a positive Schick reaction depended on the dose and the route of administration of a subsequent injection of antitoxin, and on the length of time that elapsed between the performance of the test and the administration of the antitoxin. For instance, a Schick reaction could be reduced to half its normal size either by giving 10 units of antitoxin intravenously thirty minutes, or 100 units intravenously ninety minutes, or 1,000 units intramuscularly forty-five minutes after making the test.

Nature of Investigation

In the present investigation it is assumed, as in Ker's work, that in the first few days of the disease all cases of diphtheria are potentially Schick-positive before receiving antitoxin. In making this assumption it is necessary to have strict standards by which to decide what is a case of diphtheria. The cases used for this work were a simple sample of those notified as diphtheria, and admitted to the North-Western Hospital, Hampstead, between November, 1932, and August, 1933; but only those which were undoubtedly diphtheritic from the clinical point of view, and which also yielded virulent cultures of *C. diphtheriae*, were considered to be proven cases of diphtheria.

Cases Receiving Intramuscular Serum

To begin with, only those patients who received all their antitoxin by the intramuscular route will be considered. Tests were performed as follows.

Group I.—Thirty-eight patients were Schick-tested immediately before an intramuscular injection of diphtheria antitoxin. Four of them were regarded as proven cases of diphtheria, and of these two gave positive and two negative reactions. Of the remaining thirty-four patients, fourteen yielded positive and twenty negative reactions.

Group II.—One hundred and fifty-one patients were each submitted to two Schick tests. In every case the first test took place one hour before, and the second immediately before, an intramuscular injection of antitoxin. Twenty-four patients were considered to be proven cases of diphtheria, and of these twenty-two reacted positively to both tests, and two were positive to the first but negative to the second. Of the remaining 127, eighty had positive reactions to both tests, fourteen were positive to the first and negative to the second, and thirty-three gave negative reactions to both tests.

Group III.—Three patients were each Schick-tested one hour before an intramuscular injection of antidiphtheritic serum. Two were looked upon as proven cases of diphtheria, and all three reacted positively.

Group IV.—Fifty-six patients were each submitted to two Schick tests. In every case the first test took place two hours before, and the second one hour before, an intramuscular injection of antitoxin. Sixteen patients were considered to be proven cases of diphtheria, and all of these gave positive results to both tests. Of the remaining forty cases, thirty-three were positive to both tests, one was positive to the first and negative to the second, and six were negative to both.

Table I shows the results of all Schick tests performed on patients who were regarded as proven cases of diphtheria, grouped according to the length of time the injection of antitoxin was delayed after each test. This

table is concerned with Schick tests and not with patients. If a patient is in, say, Groups II or IV, the results of his two tests are shown separately, each in its appointed row.

TABLE I

Time Elapsing between Schick Test and Intramuscular Injection of Antitoxin	Number of Tests Made	Result of Test		% +
		+	-	
0 hours	23	24	4	85.7
1 hour	42	42	0	100.0
2 hours	16	16	0	100.0

It is assumed that all the patients who formed the experimental material for Table I were potentially Schick-positive before receiving antitoxin. Four of the twenty-eight tests made immediately before the intramuscular injection of antitoxin were negative. Therefore a Schick test made immediately before such an injection of antitoxin does not give a reliable index of the patient's state of immunity at the time the test was performed. On the other hand, all of the forty-two reactions in the next row were positive. This, of course, is far from proving that all cases of diphtheria, if Schick-tested one hour before an intramuscular injection of serum, would show positive results to that test. First, these were all cases in which there was no doubt as to the diagnosis of diphtheria on clinical grounds alone. They therefore tended, on the whole, to be more severe than the average run of cases, and it is possible that they were, correspondingly, potentially more strongly Schick-positive than the average run of cases. Secondly, forty-two is a very small number from which to draw general conclusions. As might be expected, in the sixteen instances where the antitoxin was delayed for two hours after the test all the reactions were positive.

The reactions in Groups II and IV lend themselves to further consideration, because when a patient is submitted to two Schick tests the first, if positive, acts as a control on the second. Table II shows the results of the Schick reaction on all cases which were tested twice, and which reacted positively to the first test. This table is not confined to proven cases of diphtheria, but also includes those in which there was room for doubt about the diagnosis, and others which were not finally diagnosed as diphtheria at all.

TABLE II

Groups	Both Tests +	First Test + Second Test -	Total	% Positive to Both Tests
II	102	16	118	86.44
IV	49	1	50	98.00

Table II reveals that out of 118 patients in Group II who reacted positively to the test made one hour before the intramuscular injection of diphtheria antitoxin only 86.44 per cent. gave positive reactions to the test made immediately before they received antitoxin. Of the fifty patients in Group IV who reacted positively when the antitoxin was delayed two hours after the test, all but one, also yielded positive reactions when the interval between test and injection of antitoxin was only one hour. The fact that one of these fifty had a negative reaction to the second test suggests that the interval of one hour between test and antitoxin is not long enough to ensure that the result of the test is unaffected by the injected antitoxin. This is supported by the observation that in some of the Group IV cases which reacted positively to both tests the reaction to the second was weaker than the reaction to the first. (It should be mentioned that,

for the sake of simplicity, doubtful reactions were recorded as negative.)

Considering Tables I and II together, there is no doubt that the Schick test performed one hour before an intramuscular injection of diphtheria antitoxin, though subject to some extent to the nullifying influence of the injected antitoxin, yet possesses a high degree of reliability. It is further suggested that the test carried out two hours before the intramuscular injection of antitoxin is more reliable still, and can be accepted for practical purposes as giving a true index of the patient's state of immunity at the time the test was performed.

Cases Receiving Intravenous Serum

Fourteen patients who were considered to be proven cases of diphtheria were each Schick-tested twice, the first test one hour before, and the second immediately before, an intravenous injection of antidiphtheritic serum. Their Schick reactions are shown in Table III.

TABLE III

Time Elapsing between Schick Test and Intravenous Injection of Diphtheria Antitoxin	Number of Tests Made	Result of Test		% +
		+	-	
0 hours	14	1	13	7.14
1 hour	14	10	4	71.43

A comparison between Tables I and III reveals that the proportion of positive reactions to the test immediately before intramuscular antitoxin is about twelve times as great as the corresponding proportion in the intravenous series. The results of the tests made one hour before giving antitoxin show a similar but less striking difference. Tables I and III, therefore, illustrate in human beings the same principles which Glenny and Hopkins established in guinea-pigs in connexion with the length of time the antitoxin was delayed after carrying out the Schick test and with the route by which the antitoxin was given. There was no evidence, in the cases used in this work, that the inhibition of a positive Schick reaction depended on the number of units of antitoxin given. There was not, however, very much variation in the size of dose employed, the number of "inhibited" reactions was small, and there was considerable variation in the age and weight of the patients.

Conclusions

1. It is suggested that two hours is a sufficient interval in which to delay an intramuscular injection of antidiphtheritic serum after making a Schick test in order to get a reliable result to that test.

2. It has been demonstrated that antidiphtheritic serum is much more efficient in inhibiting a positive Schick reaction when introduced by the intravenous route than by the intramuscular.

I wish to express my thanks to Dr. A. Joe, medical superintendent of the North-Western Hospital, Hampstead, for suggesting the subject of this work, and for much helpful advice.

A CASE OF EVIPAN PARALYSIS

BY

J. V. LANDOR, M.D., M.R.C.P.

AND

MOHAMED SALLEH, L.M.S.

Singapore

The following case is one of widespread paralysis following the use of evipan for general anaesthesia with no premedication, and as we can find no similar case in the literature we think it may be worth recording.

A Chinese patient, aged 29, was admitted to the Johore Bahru General Hospital on February 5th, 1934, complaining of swelling, redness, and pain in the region of the left knee-joint of four days' duration. The surface appearance suggested a cellulito-cutaneous erysipelas. On February 8th operation was decided upon, and performed under evipan anaesthesia. The one gram of evipan in the usual stock ampoule was dissolved in the 10.5 c.cm. of distilled water in the other stock ampoule. Nine c.cm. of this solution was given intravenously at 11 a.m. very slowly, stopping for a few seconds after every 1/2 c.cm. and taking six minutes to introduce the total 9 c.cm. The patient began to yawn after 2 1/2 c.cm., and to snore after 4 c.cm. The operation was started at 11.10 a.m. and lasted seventeen minutes. An incision five inches long was made on the outer side of the left thigh, and a large abscess cavity was opened, evacuated of all pus, and irrigated; the abscess was found not to communicate with the knee-joint.

After the operation the patient was breathing normally and moving his eyeballs, but he did not recover full consciousness till 10.30 o'clock that night. During this long interval he made movements of the eyes, face, and limbs, and swallowing movements. His pulse was rapid (140), but had been nearly as fast before operation (134). An injection of strychnine 1/30 grain was given at 3 p.m. that day, and oxygen was then administered for half an hour because he was so long unconscious; coramine, as recommended by the manufacturers, was not available. At 10.30 p.m. he at last began to answer questions, and warm drinks were given. He was fully conscious next morning.

It was not until February 17th that the assistant surgeon in charge of the case noticed there was severe paralysis. The patient had in the meantime been gravely ill owing to his septic condition, and had not himself called attention to his paralysis; when questioned, he stated that it had been gradually coming on since the date of his operation, but had not been present before. On detailed examination there was flaccid paralysis of the trunk, so that the patient could not move himself in bed, of both lower limbs, and of the distal portion of the upper limbs. There was bilateral ankle-drop and wrist-drop. The knee-jerks, ankle-jerks, and biceps-jerks were absent; the plantar responses were flexor, and abdominal cutaneous reflexes present. There was no loss of control of the sphincters. Sensibility to touch and pain was diminished below the knees, but not affected in the upper limbs. Kahn test of the blood and of the cerebro-spinal fluid was negative.

General wasting of many muscles followed, with consequent loss of weight; by April the weight was down to 89 lb., but, unfortunately, it had not been taken earlier. On June 23rd, when recovery was almost complete, it was 100 lb. The septic condition of the leg gradually cleared up, although for several days after the operation it was spreading; the wound was healed by the middle of April, and all inflammation had then disappeared. There had been considerable pyrexia before the operation, but there was none after, except a temperature of 100° F. on the day following and a rise to a 100° on March 9th and 10th, which yielded at once to quinine. High fever occurred on April 22nd, with painful enlarged spleen and the appearance of blood and mucus in the stools; this subsided with quinine treatment in a week, and was probably malarial, though no parasites were found in the blood; there were no causative organisms in the stools.

For the paralysis the patient received massage, rhythmically interrupted sinusoidal current, and a general tonic of iron and strychnine; flexion and extension of wrists and feet

against resistance; and application of simple apparatus to prevent contractures. The paralysis gradually improved, and he was able to sit up by early April, and to walk slowly by the middle of May. By the middle of June his power was practically normal and his sensation tests also, but his tendon reflexes were still negative, and he still had very slight left-sided foot-drop.

Commentary

The manufacturers claim that no serious late consequences of evipan administration have been recorded, and in truth we have seen none in the literature we have consulted, though we have noticed one or two cases of early, though evanescent, toxic effects. The manufacturers quote authorities such as Ernst,¹ Specht,² and a committee of the Medical Research Council in London as warm advocates of evipan; Holtermann and Baetzner³ declare it to be safe; Jarman and Abel⁴ consider that the full dose is safe, though they mention low blood pressure as a contraindication. The patient in our case was admittedly very ill and emaciated before operation, but it is in just such cases that the manufacturers recommend full doses.

Willcox and others⁵ report peripheral neuritis as one of the late toxic manifestations of the barbiturates, of which evipan is one, the chemical formula being *n*-methyl-C-cyclo-hexenyl-methyl barbituric acid; Willcox mentions toxic states as greatly enhancing the susceptibility of patients to the barbiturates, and this appears to be borne out by our case.

The patient was demonstrated at a meeting of the Southern Division of the Malaya Branch of the British Medical Association on April 26th, 1934, and it was suggested that the case was one of acute beri-beri, but the prolonged unconsciousness after the injection and the great loss of power in the trunk muscles were against such an explanation. We think it was an undoubted case of late paralysis due to evipan administration, and that the lesson to be learnt is that great caution needs to be taken regarding dosage in patients already toxic.

We are indebted to the Acting Principal Medical Officer, Johore, for permission to publish this case.

Two intensive post-graduate courses have been arranged by the American Medical Association of Vienna for the six weeks beginning February 18th, 1935. These courses will provide a general survey of the newest methods and principles in the fields of gynaecology and obstetrics and of ear, nose, and throat, approximately 150 hours of lectures and clinical instruction being devoted to each of these specialties. The cost of the entire course, inclusive of life membership fee to the association, will be 900 Austrian schillings (about S. 5.20 for one dollar or S. 2.615 for £1). This is to be paid in the form of two instalments, the first of which, 200 schillings, should accompany registration, and the balance paid upon beginning the work. Applications must reach Vienna not later than January 1st, and if the minimum number of six physicians is not reached by January 15th the registering members will be notified and their deposits returned. Intensive courses of like nature and at the same cost may be arranged at any time for a minimum of seven participants in any of the specialties. All instruction is in the English language, and given by leading Viennese teachers. Further information may be had from the American Medical Association of Vienna, Alserstrasse 9, Vienna, Austria.

Clinical Memoranda

GLUCOSE-INSULIN THERAPY AND VASOVAGAL ATTACKS

The syncopal attacks described by Sir William Gowers and called by him "vasovagal" have the following signs and symptoms. The attacks begin suddenly with a sense of oppression in the stomach or chest and difficulty in breathing. There is usually precordial pain—acute in some cases, a discomfort only in others—and accompanying this is a sensation of impending death "so intense that no recollection of its falsity in preceding attacks prevents the conviction of its present reality." There is no impairment of consciousness, but often a slowing of the mental processes. The vasomotor disturbance shows itself by symmetrical coldness of the extremities, tingling, and numbness. The pulse becomes small and may be almost impalpable, and the blood pressure falls. Shivering is common, and may amount to a definite rigor. All these symptoms were present in the following case.

CASE RECORD

The patient, a woman of 58, had suffered from constant attacks of asthma for eight years, for which she had been treated in a variety of ways. In October, 1933, her myocardial condition seemed poor, and her blood pressure was low, though an electrocardiogram and a radiogram of the chest showed no signs of abnormality. She was exceedingly thin, and with a view to improving the general and myocardial nutrition ten units of insulin with two tablespoonfuls of glucose was given twice a day, as considerable improvement by this means of treatment in heart diseases has been reported from various sources (notably by Shirley Smith, *British Medical Journal*, April 22nd, 1933).

A very marked improvement in the incidence of the asthmatic attacks occurred, until in a short time she was entirely free from asthma. After a fortnight's freedom from symptoms she suddenly had a typical vasovagal attack, which within a few days was followed by a succession of such attacks, occurring so frequently that her life was despaired of. It was decided to discontinue the insulin-glucose treatment, and four-hourly injections of atropine 1/120 grain were substituted, and oxygen and adrenaline given at the times of the actual attacks. Within thirty-six hours of the commencement of these measures the syncopal attacks ceased, and she has not had one since, but the asthma promptly returned.

DISCUSSION

As, presumably, some disturbance of the sugar metabolism was the starting-point of these attacks, as soon as the patient was sufficiently recovered blood sugar estimations were done, and it was found that she had a permanently low concentration of sugar in the blood, the highest point to which it rose after a carbohydrate meal being 0.89 mg. per 100 c.cm.

Dr. Cammidge, in an article in the *British Medical Journal* of May 3rd, 1930, drew attention to the existence of chronic hypoglycaemia, not as a rare curiosity, but as a state of frequent practical importance, and in four of the cases to which he referred convulsive attacks occurred which were preventable by glucose administration.

In the case in question large doses of glucose (without insulin), together with 5-minim doses of the tincture of belladonna three times a day, have, to all appearances, prevented any further vasovagal attacks and checked the asthma. As in the previous eight years of this patient's history neither belladonna nor any other treatment attempted had had any effect on her asthma, and as she had had no vasovagal attacks before the insulin was given, the case seems to have a definite bearing on the problem of the relation of Gowers's syndrome to asthma and of both to hypoglycaemia, and appears to show that there may be some connexion between these conditions.

SUMMARY

1. A brief summary of Gowers's syndrome is given.
2. A case is described where this alternated with asthma.
3. The two conditions in this case are considered to be subsidiary to a chronic hypoglycaemia of unknown—possibly suprarenal—origin.
4. Treatment of the hypoglycaemia relieved the asthma and stopped the syncopal attacks.

My thanks and acknowledgements are due to Dr. Forest Smith, who saw the case in consultation, and with whose permission I publish these notes.

Hurstmonceux, Sussex.

L. SHILLITO, M.B., B.Ch.

TRANSPLANTATION OF A SINGLE URETER AS A MEANS OF RESTING A TUBERCULOUS BLADDER

Transplantation of the ureters in cases of ectopia vesicae or intravesical growth is a method of treatment proven and recognized. The following case illustrates, I believe for the first time, another use for this therapeutic measure.

CASE RECORD

An unmarried girl of 19, seen in September, 1932, gave a history of great frequency of micturition accompanied by considerable pain and smarting. Cystoscopy in the following month revealed both ureteric orifices much inflamed—more marked on the left side—but no other signs. A specimen of urine from the bladder and left ureter showed pus and tubercle bacilli in small numbers. A specimen from the right ureter showed normal urine. This latter finding was rather surprising, as the right ureteric orifice was definitely inflamed. A further specimen taken from this side a few days later again revealed normal urine.

In November, 1932, a left nephrectomy was performed and a small focus of caseation in a single calyx was revealed. The patient made an uninterrupted recovery, and, though her frequency and strangury were much improved, they never quite subsided. In 1933 she was still passing tubercle bacilli in the urine, though few in number, and was sent to Papworth Tuberculosis Colony, from which, feeling a little better, she discharged herself after about two months' stay. She was seen by me on several occasions after this, and a cystoscopy in the beginning of this year (1934) showed a definitely tuberculous condition of the right ureteric orifice, with advanced ulceration of the bladder. Her life was made miserable by frequent micturition, which occurred about every twenty minutes during the day and night. She lost about 2 st. in weight, and no type of drug, dietetic, or topical treatment appeared to have the slightest effect. She was kept in bed for a month without any improvement, though tying a catheter into the remaining ureter (the right) for five days brought welcome relief from frequency and pain.

In view of her pain and misery I felt that any means to relieve the frequency was justifiable, and after explaining the matter to her parents I transplanted the right (remaining) ureter into the sigmoid, by Coffey's second method, in March of this year. At operation the ureter was not appreciably thickened, and the operation was so easy that I did not tie in a ureteric catheter. Her recovery was uneventful, except for rather marked vomiting for the first two days. This I attributed chiefly to methylene-blue and hexamine pills, which I found her stomach totally incapable of retaining, although she tolerated neotropine well. A little urine was passed by the rectum on the first day, and a full amount by the third. The rectum rapidly accommodated itself to the urine, and within ten days of the operation her "frequency," now transferred to the rectum, became reduced to a two-hourly rhythm during the day, and her night sleep was interrupted only once for the bedpan.

She was discharged from hospital a month later. She is now (July) up and about, has put on over a stone in weight, and tells me she passes urine from the rectum only three or four times during the day, and not at all during the night. She feels perfectly well, and wishes to resume her work as a parlourmaid. She states that she cannot believe that for two years she was passing water every twenty to thirty minutes.

CONCLUSIONS

The following points are worth noting:

1. Whether increased well-being of the patient, combined with her freedom from pain, will allow her general condition to overcome what is probably a small focus in her only kidney remains to be seen.
2. The side-tracking of the bladder has been well worth the risk, whatever the final outcome may be.
3. In spite of being an only ureter transplanted through the sigmoid wall, no retained catheter was used or appeared necessary. This point might be worthy of note by those surgeons who feel diffident of transplanting both ureters at a time. In these cases I would suggest a retention of one catheter until the rectum discharges urine.
4. The possibility of a secondary tuberculous condition of the bowel must, of course, be borne in mind. She has no signs of it as yet.
5. The complete absence of any "abnormal" feeling in passing water, in women at least, should, I think, disabuse our minds of the present disposition to regard ureteric transplantation as an operation only to be undertaken as a last resource in certain conditions.

VERNON PENNELL, M.A., M.B., F.R.C.S.,
Honorary Surgeon, Addenbrooke's Hospital,
Cambridge.

TRAUMATIC RUPTURE OF THE HEART WITHOUT EXTERNAL INJURIES

Rupture of the heart in the circumstances mentioned below is so rare that the case is worth recording.

The patient, a boy aged 9, had his chest pressed against a wall by the back of a double-bullock cart on April 21st, 1934. When examined soon after the accident, particularly for fracture of the ribs, he showed no external injuries, nor was there any evidence of internal ones. He felt quite well

The arrow "A" points to the right ventricle opened;
arrow "B" to the ruptured left ventricle.

the following day, and was therefore allowed to go to school, where he took part in the usual games. On May 1st, while playing at school, he complained of precordial pain, and fell down dead.

The post-mortem examination revealed a haemopericardium. On removal of the clot the rupture on the anterior surface of the left ventricle was seen. The site was blackish grey, roughly circular, and about one inch by three-quarters of an inch in diameter. The rupture was probably due to contusion of the heart wall at the time of the accident and yielding of the muscle so damaged. An interesting feature would appear to be the absence of pain during the ten days preceding the rupture.

My thanks are due to Dr. J. M. Somasundaran, judicial medical officer, Colombo, who was kind enough to send the specimen to me.

H. O. GUNewardene, M.B., B.S. (Lond.).

Colombo.

Reviews

RATIONAL THERAPEUTICS

Hospital Practice for Interns is a pocket volume published by the American Medical Association¹ which provides a concise and carefully selected materia medica, and also contains a variety of useful data on such matters as the treatment of certain clinical emergencies and of poisoning, methods for the collection of specimens for biochemical analysis, etc. The authors explain the need for this volume as follows:

"Experience has shown that young physicians who fail to keep abreast of modern thought in medicine by the reading of new books and periodicals tend to deteriorate rapidly as far as concerns the standards inculcated in them in the medical college. They become a ready prey to the advertisements received directly from manufacturers of proprietary remedies, and they succumb easily to the facile flow of pseudoscience that emanates from the lips of the detail man. The lure of the fixed formula is also great, and tends to discourage thoughtful and scientific prescribing. The special mission of this book is to counteract some of the evils that have been mentioned, and to stimulate the young physician to continue the type of scientific medicine that is being taught in our medical schools."

In general it may be said that the material has been selected with great care and good judgement, and it certainly should do something to encourage young practitioners to regard drugs as chemical agents and not as charms whose potency depends on their proprietary name and style of packing. The evils which the authors of this volume seek to combat are prevalent in this country as well as in the United States. During the past year or two there has been an enormous output of literature on reform of the medical curriculum; yet scarcely anyone has emphasized the need for establishing habits of rational therapeutics during the student's course of training. The general idea among teachers appears to be that, provided the student is taught diagnosis, he will "pick up" therapeutics in his subsequent career. The trouble is that he picks the subject up from blotting-paper advertisements and commercial travellers, sources of information which are characterized by enthusiasm rather than by scientific accuracy. Too often the general result of this method of education is that the practitioner never uses an official preparation when a proprietary one is available, and often prescribes the same drug under half a dozen fancy names, being wholly ignorant of their identity. The American Medical Association has made great efforts in the past to combat this evil, and its latest venture seems to be a very useful one.

EXPERIMENTAL PHYSIOLOGY

Sir E. SHARPEY-SCHAFER's *Experimental Physiology*² and Professor D. T. HARRIS's work on the same subject have recently appeared in new editions. Sir E. Sharpey-Schafer's book, an old favourite with students of physiology, is now in its fifth edition. Its revision has been undertaken by the author himself with the co-operation of Dr. W. A. BAIN, and much new matter has been added, more especially of a kind that is likely to be of value later to the student—for whom the book is primarily intended—in his clinical work. There is considerable rearrangement of the subject-matter in some sections, and all parts of

the book show evidences of thorough revision. Many of the directions have been rewritten or amplified, and among much new matter may be mentioned descriptions of the regulations of the circulation, of the tendon and skin reflexes, of heat production in muscle, of the carotid sinus reflex, and of new apparatus that has been introduced in recent years. An indispensable addition has been made in the shape of a good index.

In the second edition of *Harris's Experimental Physiology*³ the author has adhered to his original intention of making the book of practical value to the student as a basis for his clinical work and at the same time a sufficient guide for those who propose to engage in the investigation of physiological problems in the laboratory. A new chapter has been added on *body temperature*, and one, contributed by Professor A. J. Clark, on the apparatus and methods used in practical pharmacy. The book has been further brought up to date by the addition or amplification of sections on, among other subjects, the capacity of the vascular system, group testing for blood transfusion, the chemical transmission of nerve impulses, the carotid reflex, the cardiac cycle in health and disease, the capillary circulation in man, the clinical estimation of the metabolic rate, water absorption and excretion, and the electrical analysis of the sensory discharge in nerves. These additions, with the descriptions of new apparatus, bring the work up to date as regards the requirements of the research worker.

MEAT INSPECTION

The practice of meat inspection owes much to pioneer effort in Germany, and Professor OSTERTAG's "Manual" on the subject has for long stood high in the esteem of those engaged in the work. After running into nine editions in German and four in English it has been replaced and superseded by an entirely rewritten "Text-book," this title being preferred by the author as permitting more condensation and more discussion of the general principles involved. The new book now appears in an English edition, edited by Mr. Dunlop Young and translated by Dr. C. F. Marshall.⁴

In an early section the importance is urged of the ante-mortem examination of animals intended for slaughter. Various ways of killing are noted; and weapons, pens, and traps are described. Instruments like pistols, if they destroy the medulla, are not conducive to effective bleeding. The method of electrical stunning does not labour under this disadvantage, nor does it lead to perforation of the brain membranes. This last feature allows of its being used, prior to the throat-cut, in the Jewish ritual slaughter. Operated in combination with the Weinberg casting pen, it serves to rebut the charge of cruelty which has been laid against the Jewish method of killing. The correct procedure in the examination of meat, the normal appearance and differentiation of the meat and organs of the various food animals, and departures from the normal which are within physiological limits are presented in order. Among the regional diseases tuberculosis of the udder is described and illustrated. In the chapter on animal parasites the German official instructions are quoted for rendering carcasses mildly

¹ *Experimental Physiology for Medical Students*. By D. T. Harris, M.D., D.Sc., F.Inst.P. Second edition (being the revised and enlarged edition of Anrep and Harris's *Practical Physiology*). London: J. and A. Churchill, Ltd. 1934. (Pp. 248; 230 figures, 1 plate. 12s. 6d.)

² *Text-Book of Meat Inspection (Ante-Mortem and Post-Mortem), including the Veterinary Control of Meat and Meat Products*. By Robert V. Ostertag. English edition, edited by T. Dunlop Young, O.B.E., M.R.C.V.S. Translation by C. F. Marshall, M.Sc., M.D., F.R.C.S. London: Baillière, Tindall and Cox. 1934. (Pp. xi + 743; 247 figures, 10 coloured plates. 45s.)

³ Chicago: 535, North Dearborn Street.

⁴ *Experimental Physiology*. By Sir Edward Sharpey-Schafer, F.R.S. Fifth edition, revised by the author with the co-operation of W. A. Bain, Ph.D. London: Longmans, Green and Co. 1934. (Pp. 168; 94 figures. 6s. net.)

infested with *Cysticercus bovis* fit for human consumption by exposure to cold for twenty-one days. A figure is shown of the projection trichinoscope which has taken the place of the microscope for the detection of trichinella. In the important chapter on the infective diseases, which occupies a quarter of the text, the part played by bacteriology in scientific meat inspection is strongly in evidence.

The account of bacterial meat poisoning is distinguished alike by its range and completeness. It begins with a historical review of individual outbreaks, including the great, and still enigmatical, seizure at Überehr in 1919. It deals with the *intra vitam* infection of the meat, and its infection during and after slaughter. It explores the somewhat complex history of the *Salmonella* group of bacteria, and explains their morphology, biochemistry, serology, and differentiation from one another. It discusses the question of latency in man and animals, and finally details the technique of the bacteriological examination of suspect meat, and the conclusions to be drawn from the results emerging. The fallacy of the mouse-feeding test is also pointed out.

Among other subjects dealt with is the putrefaction of meat, together with the effect of mincing in favouring its extension. Attention is devoted also to the boiling or steaming of infected meat with the object of rendering it fit for human consumption. The author, however, observes that such methods are not infallible, and states that mass infections have been known to occur. The diagrams and illustrations, in the text or in coloured plates, are of a high order. The translation has to some extent been adapted to the use of English readers by the omission of purely German references and by the addition in an appendix of a selection of Acts and Regulations which either apply to England or are in the English language. A work which originates from the hand of Professor Ostertag requires no commendation. The English translation, which is a credit to all concerned, is sure of a welcome in this country.

SPECIFICITY OF SEROLOGICAL REACTIONS

When Bordet discovered that specific immunization against microbes and toxins was only one manifestation of a universal mechanism which produced a reaction to any foreign substance injected into the body, a new era dawned in serological research. Workers quickly discovered various kinds of antibodies: an agglutinin which caused foreign cells to clump together, lysins which destroyed them, and precipitins which precipitated foreign protein bodies. All these substances were found to have a specific action—that is, one which was only evoked by the particular foreign bodies or by substances closely allied to them. Specificity is not confined to proteins but embraces simple chemical substances as well; it is at the same time the foundation of serology and one of its chief problems. Modern chemical knowledge does not extend to a complete understanding of the specific serum reactions, and it is not possible to investigate them by typical experiments with known substances.

Specificity is of course practically never absolute, but is a matter of a stronger reaction to certain antigens than to others. Even this concept does not take account of a number of phenomena which correspond in all their main particulars with serum reactions. Several vegetable toxins, such as abrin and ricin, will agglutinate blood corpuscles in much the same way as haemagglutinins. Some animal bloods are more sensitive to certain of these toxins than others. Some of the greatest differences are seen in the action of croton, the toxin of croton seeds. Hitherto these vegetable agglutinins have been largely

regarded as unspecific, but Dr. LANDSTEINER³ has produced cogent experimental evidence for a considerable and regular variation in their action. This work is a summary of a succession of papers published by him on the phenomena of serological specificity, and points the way to a definition of this group of phenomena as the dissimilar effect of a series of similar agents on a series of allied substrates, and a quantitative differentiation of specificity into grades. It is not a book for the beginner, but contains a great deal that is valuable to the research pathologist and bacteriologist. Like most German works, it is very fully documented, and is an admirable guide to the literature of the subject.

MALL OF BALTIMORE

In *Franklin Paine Mall: The Study of a Mind*,⁴ Dr. FLORENCE SABIN, who for twenty years worked in one capacity or another with the professor of anatomy at the Johns Hopkins University, has after five years of preparation brought out not only a most finished account of her former chief but also a sketch of the new birth of medicine in the United States, and in particular at the Johns Hopkins University, where this comparatively little-known pioneer unobtrusively played a most important part. He was described as the man in America who regarded "anatomy as a biological science, and rescued it from the position of the handmaid of surgery," whose name as an anatomist will be placed with those of Bichat, von Baer, and W. His, who founded an institute of embryology, and instigated the plan for full-time clinical teaching by which opportunities for research were made available in the clinics. Of German descent he was born in Iowa, and when 18 years of age entered the University of Michigan, where the medical course had just been raised to three years. It is rather surprising to learn that fifty years ago the proposal of President C. W. Eliot of Harvard, that American medical students should, for admission, be required to be able to read and write, was regarded as a radical and daring reform, likely to limit the number of medical students too greatly for the country's needs. Mall obtained the degree of M.D. in 1883, and then, as was often the procedure, went to Germany for clinical instruction. But the real work he undertook there was research, first in embryology under Wilhelm His on the thymus. A most interesting account is given of how he arrived at a conclusion different from that previously published by His, who, however, subsequently admitted it to be correct. Mall next went to Leipzig, where he became a favourite pupil of Carl Ludwig, who exerted a life-long influence on him; a series of charming letters from Ludwig is quoted, and Mall, when trying to express his gratitude, was told by Ludwig to "pass it on" to others, which became the leading motive of his life.

Returning to America, Mall was for three years pathological fellow at the Johns Hopkins University under Welch, and became associated with W. S. Halsted; then, somewhat changing his line of work, he was in 1889 appointed adjunct professor of anatomy at the new Clark University, Worcester, Massachusetts, where, however, the conditions were far from satisfactory; accordingly, he accepted an invitation from the University of Chicago to organize an institute of biology, and in a year had one on new lines in working order. But after this short interlude there came the call to return to the Johns Hopkins University as the first professor of anatomy, which he accepted and held until his death in 1917.

³ *Die Spezifität der Serologischen Reaktionen*. Von Dr. K. Landsteiner. Berlin: J. Springer, 1933. (Pp. 123. RM 8.60; geb. RM. 9.80.)

⁴ *Franklin Paine Mall: The Story of a Mind*. By Florence Sabin. Baltimore: The Johns Hopkins Press; London: H. Milford, Oxford University Press. (Pp. 342; 8 figures. 12s. 6d. net.)

These are the bare outlines of the intensely active life of one of the makers of the Great School where Osler, Welch, Halsted, and Howard Kelly were the four chiefs represented in the famous Sargent portraits. The story is told with sympathetic understanding, and in a fascinating manner reveals the personality of a great advocate of research and of the highest ideals for medical education.

Notes on Books

A second edition of *Massage and Remedial Exercises*,⁷ by Miss NOËL TIDY, has been called for within eighteen months of the appearance of the first, an indication of the welcome extended to this handbook of physical treatment. Advantage has been taken of this opportunity to improve and extend certain parts. Flat-foot is now discussed on more up-to-date lines, and some extra notes on light and electrical therapy have been added. The book is comprehensive and practical, and the lines of treatment are clearly shown in letterpress and figures. If the book still lies open to the criticism that here and there good judgement as regards the avoidance of risks by the lay physiotherapist seems to be taken for granted, it should be remembered that supervision by a medical practitioner is always presumed.

With a light and attractively whimsical touch which relieves the sordid details of crime, Dr. HAROLD DEARDEN, in *Death under the Microscope: Some Cases of Sir Bernard Spilsbury and Others*,⁸ brings together twenty-one accounts of medico-legal interest. This collection of true medical detective stories, besides being eminently readable, is a useful guide in showing the logical and, when pointed out, obviously correct steps in establishing the guilt of the ingenious murderer or poisoner. The account of Dr. Pritchard of Glasgow, who in 1865 poisoned both his wife and his mother-in-law, is an example of the excellent way Dr. Dearden can marshal the facts of a case.

In the little work on *Medicine in Persia*,⁹ which forms the latest addition to the Clio Medica Series, Dr. CYRIL ELGOOD, late physician to the British Legation at Teheran, states that the medical history of Persia may be divided into two periods—namely, the pre-Moslem or Avestan period, in which the teachings of Zoroaster were the predominant source of theory and practice, and the Muslim or Arabian period, in which the source was pre-eminently Greek. The book consists of seven chapters devoted respectively to the mythological and Achaemenian Ages, the Seleucid and Sassanid Ages, the Caliphate and Baghdad School of Medicine, Avicenna, the decay of the Caliphate, the Mongol and Safavid Dynasties, and the Qajar and Pahlavi Dynasties. A table of political and medical dates of Persian history compared with current events in Europe is appended. Dr. Elgood maintains that though Persian medicine cannot claim equality with the primitive Greek or modern Western School, it reveals, if it does not surpass, the Roman, Byzantine, and Alexandrian Schools, owing to the introduction of numerous drugs still in use to-day, such as nux vomica, croton oil, rhubarb, senna, and sugar, the description of various diseases, especially small-pox, jaundice, and leishmaniasis, and the preservation of the great Hippocratic doctrines.

We think it safe to predict that the *Concise Oxford French Dictionary*,¹⁰ compiled by the late ABEL CHEVALLEY, will soon find a place in many bookshelves beside the *Concise Oxford Dictionary* and Fowler's invaluable *Modern English Usage*. These three volumes are alike in price

⁷ *Massage and Remedial Exercises in Medical and Surgical Conditions*. By Noel M. Tidy. Second edition. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1934. (Pp. 430; 178 figures. 15s. net.)

⁸ *Death under the Microscope: Some Cases of Sir Bernard Spilsbury and Others*. By Harold Dearden. London: Hutchinson and Co. 1934. (Pp. 288. 9s. 6d. net.)

⁹ *Medicine in Persia*. By Cyril Elgood, M.D., M.R.C.P. New York: Paul B. Hoeber, Inc. 1934. (Pp. xiii + 105; 11 figures. 1.60 dollars.)

¹⁰ *The Concise Oxford French Dictionary*. Compiled by Abel Chevalley and Marguerite Chevalley. London: H. Milford, Oxford University Press. 1934. (Pp. 928; illustrated. 7s. 6d. net.)

and binding, and their contents are informed by the same blend of accurate scholarship and ripe common sense. The latest member of the series is a "current use" French-English dictionary of nearly 40,000 judiciously chosen words, the general aim being not "to give information about the things represented by French words, but only about the nearest equivalence between French and English of the words and phrases which represent these things." It is based on a fresh survey of the field of modern French speech and literature, and of standard French literature. The commoner the word the more space and care are given to its uses and meanings and their nearest English equivalents. Printed indications and brief cautions are inserted wherever the student or translator needs to be warned against a pitfall: "beware of apparent analogy." Pronunciation is indicated by a simplified form of the Passy-Michaelis-system of phonetic notation. Typographically this dictionary is in all respects worthy of the Clarendon Press; it gives an immense amount of useful information in the least possible space without sacrificing legibility by the use of microscopical type, and its price is most reasonable.

Preparations and Appliances

NEW DRAINAGE BAG FOR PERMANENT CYSTOSTOMY

Mr. TERENCE MILLIN, F.R.C.S. (London, W.1), writes:

The apparatus illustrated is an attempt to alleviate the lot of the patient condemned to a permanent cystostomy. It has been in use now for almost a year in the hospital and private practice of myself and a number of colleagues, and has given much satisfaction. The discomfort of a bag "flapping" against the leg while walking is avoided. The emptying of the bag can be carried out quite surreptitiously in a public

lavatory through the usual exitus from the trousers, saving the penny demanded for privacy when the older type of bag is being operated! The capacity of the bag is twenty ounces, but it is preferable to empty it when containing between eight to ten ounces. Its inlet is provided with a valve, preventing regurgitation from the container to the bladder. The theoretical objection of "uphill drainage" has not been substantiated in practice. It is, of course, all-important for the satisfactory functioning of any cystostomy that the fistula should be made sufficiently remote from the symphysis pubis.

The apparatus has been made for me by Messrs. Down Bros., St. Thomas's Street, London, S.E.1.

EUBION

"Eubion" tablets (Messrs. Evans Sons Lescher and Webb) contain vitamin A concentrate and vitamin D made up with a chocolate basis. The makers state that the vitamin A content of each tablet is equivalent to a tablespoonful of best quality cod-liver oil. It is generally recognized that administration of this vitamin may in many cases improve the condition of epithelial tissues, and thereby increase resistance to infection. Therefore its prophylactic and therapeutic uses are numerous. "Eubion" tablets have a pleasant taste, and constitute an acceptable substitute for cod-liver oil.

GEORGES DREYER'S SCIENTIFIC WORK AT OXFORD

REVIEW AND APPRECIATION BY A COLLEAGUE

A public lecture was given at Oxford on November 16th by Dr. E. W. Ainley Walker, University Reader in Pathology, on the scientific work of the late Georges Dreyer, Professor of Pathology at Oxford University from 1907 until his recent death. With much of the work he described Dr. Ainley Walker had himself been closely associated.

Dreyer's first important publication from Oxford was an account of his method, modified and elaborated from Madsen's, of measuring the agglutination titre of blood serum. This had already been published by Dreyer in his native Denmark, but on the whole had escaped attention in this country, and he proceeded accordingly to provide an easily accessible account of it in English literature. He had converted the rough qualitative test into a quantitative one, measuring the exact amount of agglutinative action present, so that all observations carried out by this technique are comparable irrespective of time, place, and individual observer.

THE SOURCE OF IMMUNE PRODUCTS

The first new work to which Dreyer set himself was to throw further light on the source of agglutinins and similar immune products and the general mechanism of the protective reaction. In this work he was assisted by Dr. Ainley Walker, and together they showed by experiment that in animals specifically immunized by inoculation with the bacillus proper to the agglutinins under examination subsequent inoculation with a non-specific micro-organism caused a new rise in titre of the specific agglutinins which followed a "curve" of the same character as that produced by specific inoculation. One very important site of formation of these immune bodies was the *blood-forming tissues and the reticulo-endothelial system*. It appeared probable that the leucocytes of the blood, liberated into the circulation from these tissues, would themselves contain definite amounts of the agglutinins during the period of their active formation. Blood serum was accordingly compared with blood plasma for agglutinin content, and experiments established the fact that the leucocytes of the blood, as well as of the plasma, contained appreciable amounts of agglutinin, and that these cells, and the cells and tissues from which they arose, were a source—not necessarily the only source—of these products of the immunity reaction.

An attempt was next made to ascertain the total quantity of agglutinin present in the circulating blood of immunized animals instead of merely its percentage concentration, and Dreyer undertook a reinvestigation of blood volume in certain animals. This work established the view by a mass of experimental results that the volume of the circulating blood must itself be related numerically to the area of the body surface; also that the bore of the principal channels carrying the blood, as well as the lumen of the tube which admitted to the body the oxygen needed for combustion, would both be found proportional to the surface area in animals of different size and weight throughout any given species. Some controversy arose with workers who had used the carbon monoxide inhalation method for determining blood volume, and who accepted it as a fraction of the weight, but Dreyer and his collaborators convinced themselves that the inhalation method was unreliable, and the conception that within a given species of warm-blooded animal the blood volume of the individual was proportional to the surface area of the body had since been independently confirmed.

EFFECT OF HIGH ALTITUDE UPON BLOOD

The blood-volume formula was again confirmed by the fact that its application gave satisfactory solution to

certain other problems, especially the effect of high altitude upon blood. When Dreyer began his experiments it was still uncertain how the rapid adaptation to diminished oxygen tension shown by successful climbers during an ascent was brought about. Dreyer and Ainley Walker formulated a working hypothesis that the immediate adjustment to gradual lowering of the oxygen tension took place by a concentration of the blood so that more haemoglobin was present per unit volume, and therefore more oxygen could be taken up in its passage through the lungs than when only the normal amount of haemoglobin was present. Experiments with rabbits showed that the constant of the blood-volume formula changed with change of altitude, so that the effect of increased altitude was to bring about a proportionate and marked concentration of the blood, thus increasing the amount of haemoglobin present per unit volume; but it was also proved that there was a further adaptation to altitude by the gradual production of fresh haemoglobin, additional to the animal's original supply.

In other directions it was possible, with this formula for blood volume, to open up useful lines of investigation. One of these concerned the relation of dosage to size. Hitherto the weight of the animal had been regarded as the governing factor, but certain incongruities made their appearance when that was taken, which disappeared when the doses were recalculated in relation to the body surface—that is to say, the blood volume—of the individual.

DREYER'S WAR WORK AND AFTER

With the outbreak of war Dreyer turned his attention to the diagnosis and prophylaxis of the enteric fevers. In numerous communications he, with various co-workers, demonstrated the method of differential serum diagnosis in inoculated persons. He also took the opportunity to acquire new knowledge by working out in detail the form and the time relations of the immunity curves for agglutinins following doses of the vaccine. On becoming attached to the Royal Flying Corps, Dreyer took up the problem presented by flying at high altitudes, designing an apparatus for delivering an accurately controlled supply of oxygen into the breathing mask and devising a simple procedure for testing the effect of oxygen want. He also interested himself in certain problems connected with growth, recalculating the growth formula from new measurements on a more widely spread sample of the population and studying the development of physique, with special reference to the vital capacity of the lungs and the chest measurement.

The application of some of this work to tuberculous subjects at Brompton Hospital led Dreyer to consider the possibility of specific immunization against tuberculosis. With Vollum he prepared a defatted or washed-out vaccine, which gave satisfactory results in the treatment of tuberculous laboratory animals, and optimistic reports by certain workers of trials on man were forthcoming. Unfortunately, however, the promise failed to mature when the vaccine was released, under the control of the Medical Research Council, for extended clinical trial. Dreyer had been persuaded, against his better judgement, to a publication of his results, which thus proved to have been premature, and he was naturally chagrined, though he never complained of having been misled by the too hasty enthusiasm of others. But he continued with the subject, and only this year he had the satisfaction of publishing the results of a nine years' field experiment on a herd of Danish cows, which seemed to prove conclusively that his diaplyte vaccine possessed an indubitable protective value in cattle. Another direction in which his work in this field had been fruitful was in demonstrating that under certain conditions of culture in the laboratory the B.C.G. vaccine reacquired virulence for animals, so that it might be suspected of possessing a capacity to do so when placed in favourable surroundings within the human body.

The lecturer deplored the fact that Dreyer's untimely death had deprived so much useful inquiry of its stimulating direction and insight.

PUBLIC HEALTH PROBLEMS OF INDIA

Lieut.-Colonel A. J. H. Russell, I.M.S., the successor as Public Health Commissioner with the Government of India to Major-General Graham, calls attention in his first annual report, which covers the year 1932, to certain of the more important problems which have to be faced in modern India. Compiled on the eve of new constitutional reforms in that country, it is natural that the report should emphasize the point that the health and welfare of the peoples of India are the most weighty questions which the new Governments—Federal and Provincial—will have to face as soon as they come into being.

ECONOMIC PROBLEMS

The population of British India in 1931 was estimated by the census as being 271,526,933; that of India as a whole was 352,837,778. The rate of increase during the decennium 1921–31 was no less than 10.6 per cent., and various competent authorities have agreed that this will be about the normal for the future in the absence of any catastrophic occurrence like the influenza epidemic of 1918. Since the date of the census the usual epidemic diseases of cholera, plague, and small-pox have all shown large decreases in incidence, while famine in a death-dealing form has been unknown. The total population of India must now number, therefore, about 365 millions, and the next census will probably produce a total of nearly 50 millions more than that of 1931. Where is this large increase of population to find bread and employment? Can improved methods of agriculture, and the extension of cultivation to unused land provide the additional food supplies required? Even to-day the diet of many millions of the Indian people is not such as can maintain physical efficiency and health. There is, therefore, also another problem to be faced, the taking of energetic steps for the prevention of disease, and equally energetic measures for the education of the people in regard to mastery over environment. There will have to come a wide development of both central and provincial health departments, manned by experts capable of advising on the many difficult health problems which confront the leaders of India, for on the lines of action adopted for their solution will depend the prosperity, health, and welfare of many generations yet unborn.

In 1932 the birth rate for British India was 33.7 compared with 34.3 in the previous year; the death rate was 21.6 compared with 24.8; and the infantile mortality rate fell from 178.8 to 168.7. The total area harvested was 9 per cent. below normal. The economic position of the agricultural population was depressed owing to the fall in prices, the resultant contraction in the credit of the cultivator, and the general depression in trade. Certain waterlogged areas were, however, greatly improved by drainage schemes.

MEDICAL PROBLEMS

India is still the chief endemic focus of small-pox in the whole world. The proportion of vaccinated persons, although higher in urban than in rural areas, is still far below the figure necessary to prevent epidemic outbreaks. Again, though the total annual number of vaccinations approximates 15 millions, this is quite insufficient to ensure the immunity of the general population against infection. Colonel Russell remarks that every provincial health department has fought continually for many years against the general apathy which persists even in the face of virulent epidemics, but the percentage of the unvaccinated will remain high, and the incidence of this fell disease be maintained, until compulsory vaccination and revaccination are instituted generally. These will be the more effective in that the maintenance of potency in the seed lymph has already been placed on a satisfactory basis, and the problem of distributing lymph to the remotest villages has been successfully solved. During the past four or five years no single case of post-vaccinal encephalitis has been recorded. Help in the campaign against the disease has been afforded by the discovery of

the facts that small-pox in India tends to become more prevalent and more virulent during the drier months of the year, when conditions of low relative humidity exist, and that, by noting changes in relative humidity, especially in dry areas, this indicator can be used to forecast epidemics of small-pox well in advance of their occurrence.

There was a decline in treated cases of malaria from 11½ millions in 1931 to 11 millions in 1932. An official inquiry brought to light the fact that quinine is seldom used in therapeutically adequate amounts, and that the quantities consumed can have little or no effect on the malarial infections so widely prevalent in many parts of India. Mortality in connexion with childbirth is very high, and the problem of maternal deaths is even greater than was supposed. The main causes of this mortality lie in social customs which cannot be quickly influenced, but an extension of the training of midwives, both European and native, would be highly beneficial. The training of illiterate dais is a tedious business, yet the numbers of even partially educated women who are ready to become midwives is still very small, and the ancient prejudice against work which is regarded as "unclean" still lingers. One cheering aspect of the campaign is the increasing appreciation of the work of ante-natal clinics. The amount of child welfare work is pitifully small and is showing but little tendency to grow, rural areas being as yet almost untouched. Depression in trade is also preventing its spread in industrial areas. Colonel Russell points out that health work among women and children needs more and better forms of propaganda than are at present available. The material is poor, he states, and badly thought out; many of the baby and health weeks are little more than "tamashas." He suggests that voluntary societies, which are responsible for much of this work, would do well to pay more attention to this aspect of their activities.

FUTURE POSSIBILITIES

Concluding a report which is very clearly set out, although there is an immense amount of most interesting detail in its 400 pages, he pleads for lessening the restrictions on medical research in India, which is so vital for the prevention of diseases endemic in that country. He thinks that in rural areas it should be possible for a group of districts to keep a laboratory in full work, acting as the centre for all examinations and investigations required. Cerebro-spinal meningitis is increasing seriously, and great epidemics are threatened, particularly in the more congested centres of population. The Central Research Institute at Kasauli has recently had under preparation an anti-meningococcus vaccine manufactured from cultures originally taken from cases in Delhi, and this is now being tried in selected communities. Attempts are being made to obtain accurate records of all persons inoculated with the vaccine. It is hoped that sufficiently reliable data will become available in due course to permit of a reasonable evaluation of this new prophylactic.

Colonel Russell ends his survey on a gloomy note. Financial stringency has led to universal and often sweeping reductions in expenditure, even on such primary needs as protected water supplies and drainage schemes, medical research, anti-malarial works, medical inspection of school children, and maternity relief activities. Fresh developments have almost entirely disappeared. The public health problems confronting the new Governments in India are menacing, and it is hard to see how they can be faced at all hopefully by the present weakened central health organization. "One of the most immediate requirements," he writes, "is an All-India Public Health Act, which would lay down the broad principles on which all public health development should be based. Unfortunately the financial position has even forbidden the creation of the Central Board of Health which was suggested by the Simon Commission, and which had been planned by the present member in charge of public health as a first stage in effecting closer co-ordination between individual provinces in matters of public health. These and other developments must, it seems, await happier and more prosperous days."

GEORGES DREYER'S SCIENTIFIC WORK AT OXFORD

REVIEW AND APPRECIATION BY A COLLEAGUE

A public lecture was given at Oxford on November 16th by Dr. E. W. Ainley Walker, University Reader in Pathology, on the scientific work of the late Georges Dreyer, Professor of Pathology at Oxford University from 1907 until his recent death. With much of the work he described Dr. Ainley Walker had himself been closely associated.

Dreyer's first important publication from Oxford was an account of his method, modified and elaborated from Madsen's, of measuring the agglutination titre of blood serum. This had already been published by Dreyer in his native Denmark, but on the whole had escaped attention in this country, and he proceeded accordingly to provide an easily accessible account of it in English literature. He had converted the rough qualitative test into a quantitative one, measuring the exact amount of agglutinative action present, so that all observations carried out by this technique are comparable irrespective of time, place, and individual observer.

THE SOURCE OF IMMUNE PRODUCTS

The first new work to which Dreyer set himself was to throw further light on the source of agglutinins and similar immune products and the general mechanism of the protective reaction. In this work he was assisted by Dr. Ainley Walker, and together they showed by experiment that in animals specifically immunized by inoculation with the bacillus proper to the agglutinins under examination subsequent inoculation with a non-specific micro-organism caused a new rise in titre of the specific agglutinins which followed a "curve" of the same character as that produced by specific inoculation. One very important site of formation of these immune bodies was the blood-forming tissues and the reticulo-endothelial system. It appeared probable that the leucocytes of the blood, liberated into the circulation from these tissues, would themselves contain definite amounts of the agglutinins during the period of their active formation. Blood serum was accordingly compared with blood plasma for agglutinin content, and experiments established the fact that the leucocytes of the blood, as well as of the plasma, contained appreciable amounts of agglutinin, and that these cells, and the cells and tissues from which they arose, were a source—not necessarily the only source—of these products of the immunity reaction.

An attempt was next made to ascertain the total quantity of agglutinin present in the circulating blood of immunized animals instead of merely its percentage concentration, and Dreyer undertook a reinvestigation of blood volume in certain animals. This work established the view by a mass of experimental results that the volume of the circulating blood must itself be related numerically to the area of the body surface; also that the bore of the principal channels carrying the blood, as well as the lumen of the tube which admitted to the body the oxygen needed for combustion, would both be found proportional to the surface area in animals of different size and weight throughout any given species. Some controversy arose with workers who had used the carbon monoxide inhalation method for determining blood volume, and who accepted it as a fraction of the weight, but Dreyer and his collaborators convinced themselves that the inhalation method was unreliable, and the conception that within a given species of warm-blooded animal the blood volume of the individual was proportional to the surface area of the body had since been independently confirmed.

EFFECT OF HIGH ALTITUDE UPON BLOOD

The blood-volume formula was again confirmed by the fact that its application gave satisfactory solution to

certain other problems, especially the effect of high altitude upon blood. When Dreyer began his experiments it was still uncertain how the rapid adaptation to diminished oxygen tension shown by successful climbers during an ascent was brought about. Dreyer and Ainley Walker formulated a working hypothesis that the immediate adjustment to gradual lowering of the oxygen tension took place by a concentration of the blood so that more haemoglobin was present per unit volume, and therefore more oxygen could be taken up in its passage through the lungs than when only the normal amount of haemoglobin was present. Experiments with rabbits showed that the constant of the blood-volume formula changed with change of altitude, so that the effect of increased altitude was to bring about a proportionate and marked concentration of the blood, thus increasing the amount of haemoglobin present per unit volume; but it was also proved that there was a further adaptation to altitude by the gradual production of fresh haemoglobin, additional to the animal's original supply.

In other directions it was possible, with this formula for blood volume, to open up useful lines of investigation. One of these concerned the relation of dosage to size. Hitherto the weight of the animal had been regarded as the governing factor, but certain incongruities made their appearance when that was taken, which disappeared when the doses were recalculated in relation to the body surface—that is to say, the blood volume—of the individual.

DREYER'S WAR WORK AND AFTER

With the outbreak of war Dreyer turned his attention to the diagnosis and prophylaxis of the enteric fevers. In numerous communications he, with various co-workers, demonstrated the method of differential serum diagnosis in inoculated persons. He also took the opportunity to acquire new knowledge by working out in detail the form and the time relations of the immunity curves for agglutinins following doses of the vaccine. On becoming attached to the Royal Flying Corps, Dreyer took up the problem presented by flying at high altitudes, designing an apparatus for delivering an accurately controlled supply of oxygen into the breathing mask and devising a simple procedure for testing the effect of oxygen want. He also interested himself in certain problems connected with growth, recalculating the growth formula from new measurements on a more widely spread sample of the population and studying the development of physique, with special reference to the vital capacity of the lungs and the chest measurement.

The application of some of this work to tuberculous subjects at Brompton Hospital led Dreyer to consider the possibility of specific immunization against tuberculosis. With Vollum he prepared a defatted or washed-out vaccine, which gave satisfactory results in the treatment of tuberculous laboratory animals, and optimistic reports by certain workers of trials on man were forthcoming. Unfortunately, however, the promise failed to mature when the vaccine was released, under the control of the Medical Research Council, for extended clinical trial. Dreyer had been persuaded, against his better judgement, to a publication of his results, which thus proved to have been premature, and he was naturally chagrined, though he never complained of having been misled by the too hasty enthusiasm of others. But he continued with the subject, and only this year he had the satisfaction of publishing the results of a nine years' field experiment on a herd of Danish cows, which seemed to prove conclusively that his diaplyte vaccine possessed an indubitable protective value in cattle. Another direction in which his work in this field had been fruitful was in demonstrating that under certain conditions of culture in the laboratory the B.C.G. vaccine reacquired virulence for animals, so that it might be suspected of possessing a capacity to do so when placed in favourable surroundings within the human body.

The lecturer deplored the fact that Dreyer's untimely death had deprived so much useful inquiry of its stimulating direction and insight.

PUBLIC HEALTH PROBLEMS OF INDIA

Lieut.-Colonel A. J. H. Russell, I.M.S., the successor as Public Health Commissioner with the Government of India to Major-General Graham, calls attention in his first annual report, which covers the year 1932, to certain of the more important problems which have to be faced in modern India. Compiled on the eve of new constitutional reforms in that country, it is natural that the report should emphasize the point that the health and welfare of the peoples of India are the most weighty questions which the new Governments—Federal and Provincial—will have to face as soon as they come into being.

ECONOMIC PROBLEMS

The population of British India in 1931 was estimated by the census as being 271,526,933; that of India as a whole was 352,837,778. The rate of increase during the decennium 1921-31 was no less than 10.6 per cent., and various competent authorities have agreed that this will be about the normal for the future in the absence of any catastrophic occurrence like the influenza epidemic of 1918. Since the date of the census the usual epidemic diseases of cholera, plague, and small-pox have all shown large decreases in incidence, while famine in a death-dealing form has been unknown. The total population of India must now number, therefore, about 365 millions, and the next census will probably produce a total of nearly 50 millions more than that of 1931. Where is this large increase of population to find bread and employment? Can improved methods of agriculture, and the extension of cultivation to unused land provide the additional food supplies required? Even to-day the diet of many millions of the Indian people is not such as can maintain physical efficiency and health. There is, therefore, also another problem to be faced, the taking of energetic steps for the prevention of disease, and equally energetic measures for the education of the people in regard to mastery over environment. There will have to come a wide development of both central and provincial health departments, manned by experts capable of advising on the many difficult health problems which confront the leaders of India, for on the lines of action adopted for their solution will depend the prosperity, health, and welfare of many generations yet unborn.

In 1932 the birth rate for British India was 33.7 compared with 34.3 in the previous year; the death rate was 21.6 compared with 24.8; and the infantile mortality rate fell from 178.8 to 168.7. The total area harvested was 9 per cent. below normal. The economic position of the agricultural population was depressed owing to the fall in prices, the resultant contraction in the credit of the cultivator, and the general depression in trade. Certain waterlogged areas were, however, greatly improved by drainage schemes.

MEDICAL PROBLEMS

India is still the chief endemic focus of small-pox in the whole world. The proportion of vaccinated persons, although higher in urban than in rural areas, is still far below the figure necessary to prevent epidemic outbreaks. Again, though the total annual number of vaccinations approximates 15 millions, this is quite insufficient to ensure the immunity of the general population against infection. Colonel Russell remarks that every provincial health department has fought continually for many years against the general apathy which persists even in the face of virulent epidemics, but the percentage of the unvaccinated will remain high, and the incidence of this fell disease be maintained, until compulsory vaccination and revaccination are instituted generally. These will be the more effective in that the maintenance of potency in the seed lymph has already been placed on a satisfactory basis, and the problem of distributing lymph to the remotest villages has been successfully solved. During the past four or five years no single case of post-vaccinal encephalitis has been recorded. Help in the campaign against the disease has been afforded by the discovery of

the facts that small-pox in India tends to become more prevalent and more virulent during the drier months of the year, when conditions of low relative humidity exist, and that, by noting changes in relative humidity, especially in dry areas, this indicator can be used to forecast epidemics of small-pox well in advance of their occurrence.

There was a decline in treated cases of malaria from 11½ millions in 1931 to 11 millions in 1932. An official inquiry brought to light the fact that quinine is seldom used in therapeutically adequate amounts, and that the quantities consumed can have little or no effect on the malarial infections so widely prevalent in many parts of India. Mortality in connexion with childbirth is very high, and the problem of maternal deaths is even greater than was supposed. The main causes of this mortality lie in social customs which cannot be quickly influenced, but an extension of the training of midwives, both European and native, would be highly beneficial. The training of illiterate dais is a tedious business, yet the numbers of even partially educated women who are ready to become midwives is still very small, and the ancient prejudice against work which is regarded as "unclean" still lingers. One cheering aspect of the campaign is the increasing appreciation of the work of ante-natal clinics. The amount of child welfare work is pitifully small and is showing but little tendency to grow, rural areas being as yet almost untouched. Depression in trade is also preventing its spread in industrial areas. Colonel Russell points out that health work among women and children needs more and better forms of propaganda than are at present available. The material is poor, he states, and badly thought out; many of the baby and health weeks are little more than "tamashas." He suggests that voluntary societies, which are responsible for much of this work, would do well to pay more attention to this aspect of their activities.

FUTURE POSSIBILITIES

Concluding a report which is very clearly set out, although there is an immense amount of most interesting detail in its 400 pages, he pleads for lessening the restrictions on medical research in India, which is so vital for the prevention of diseases endemic in that country. He thinks that in rural areas it should be possible for a group of districts to keep a laboratory in full work, acting as the centre for all examinations and investigations required. Cerebro-spinal meningitis is increasing seriously, and great epidemics are threatened, particularly in the more congested centres of population. The Central Research Institute at Kasauli has recently had under preparation an anti-meningococcus vaccine manufactured from cultures originally taken from cases in Delhi, and this is now being tried in selected communities. Attempts are being made to obtain accurate records of all persons inoculated with the vaccine. It is hoped that sufficiently reliable data will become available in due course to permit of a reasonable evaluation of this new prophylactic.

Colonel Russell ends his survey on a gloomy note. Financial stringency has led to universal and often sweeping reductions in expenditure, even on such primary needs as protected water supplies and drainage schemes, medical research, anti-malarial works, medical inspection of school children, and maternity relief activities. Fresh developments have almost entirely disappeared. The public health problems confronting the new Governments in India are menacing, and it is hard to see how they can be faced at all hopefully by the present weakened central health organization. "One of the most immediate requirements," he writes, "is an All-India Public Health Act, which would lay down the broad principles on which all public health development should be based. Unfortunately the financial position has even forbidden the creation of the Central Board of Health which was suggested by the Simon Commission, and which had been planned by the present member in charge of public health as a first stage in effecting closer co-ordination between individual provinces in matters of public health. These and other developments must, it seems, await happier and more prosperous days."

FACTORS IN THE REDUCTION OF MATERNAL MORTALITY

A meeting of the National Baby Week Council, presided over by Dame LOUISE MCLROY, was held on November 14th, when the subject for discussion was stated as a problem for the propagandist: "Has Ante-natal Work Reduced Maternal Mortality?"

Dr. T. WATTS EDEN pointed out that not only was maternal mortality obstinately high, but neo-natal mortality—that is, the deaths of infants during the first four weeks of life—was high also. Ten years ago neo-natal mortality was about 40 per cent. of the total infant mortality; it was now 50 per cent. Yet during this period there had been a great extension of ante-natal work, and of expectant mothers 42 per cent. actually came to the clinics, while probably 80 per cent. had some form of ante-natal supervision. Superficially it would appear that ante-natal work had failed to reduce maternal mortality. During the period that ante-natal work had been developing great changes had come over obstetric practice, such as an increase in the number of beds devoted to maternity cases. In Manchester ten years ago only 11 per cent. of confinements took place in hospital; in 1933 the figure was over 40 per cent. Nevertheless, maternal mortality had slightly risen in Manchester during that period. Probably ante-natal work was unequal in quality. Year by year the concept of what it included was broadening. The clinics required directors of ability, experience, and training. A weak point in the system was the rule in teaching hospitals for the ante-natal clinic to be placed in charge of a junior member of the obstetric staff. More ante-natal beds were necessary—perhaps more necessary at the present juncture than beds for confinements. Public provision for the working mother during the last month of her pregnancy was also needed.

Dr. G. F. MCCLEARY, late of the Ministry of Health, pointed out that the maternal mortality rate was based on a denominator which consisted of the number of live births registered and a numerator which consisted of the deaths classified by the Registrar-General as due to pregnancy and child-bearing. The denominator was plain sailing, but the numerator depended upon the system of classification obtaining, which had not remained constant. Further, the denominator included live births only, whereas the numerator took into account maternal deaths due to stillbirths and abortions, and for abortions no adjustment could be made. That would not signify if the proportion of abortions to live births remained constant, but there was reason to believe that abortion was becoming more prevalent, so that the numerator tended to increase without any corresponding increase in the denominator, with the result that the quotient went up. In recent years, again, medical certification had become more precise, and this tended to increase the apparent mortality. The decline in the birth rate also had increased the proportion of first pregnancies to the whole number, and first pregnancies were more dangerous than subsequent ones. With all these allowances, however, the figure for maternal mortality was intolerably high. Ante-natal clinics needed to be supported by the provision of pre-maternity beds and an adequate midwifery service.

Dr. ETHEL CASSIE, senior assistant medical officer of health for maternity and child welfare, Birmingham, said that experience had shown that at least 20 to 25 per cent. of women required institutional care and treatment at some time during pregnancy. Without the provision of ante-natal beds, ante-natal supervision was a cruel farce. Women's lives were not going to be saved by a few examinations at the clinics. Nutrition in pregnancy was a burning question. Milk sent into the home would be given to the other children, and not consumed by the mother, and badly nourished women would not go to dinners at the clinics and leave their families dinnerless. The only solution was a minimum family income sufficient to avoid malnutrition. The State provided old

age and widows' pensions; why not pregnancy and nursing benefit? Finally, many women were physically unfit to be mothers; here it was not ante-natal care that was needed, but the prevention of pregnancy.

After some further discussion, in which the need for consultant services provided by local authorities, for adequate post-natal supervision, for pre-marital examinations and certificates of fitness for marriage, and for the provision of home helps before and after parturition were variously urged, Dame LOUISE MCLROY summed up by saying that it was out of the question to turn human beings into a stock farm, however much that might be wished; also that at the back of every scheme for the betterment of the poor mother was the jealous ratepayer. One thing which she thought it most necessary to overcome was the existing break in continuity of supervision. At present a woman might be under one medical man during the ante-natal period, under another during the confinement, and perhaps under a third for any subsequent complication. She thought too much attention was paid to pelvic and abdominal conditions, and too little to general nutrition. Post-natal supervision, with beds where the results of obstetric misadventures might be set right, was also a necessity.

BRITISH EMPIRE CANCER CAMPAIGN

In the absence of Lord Reading, Sir Holburt Waring (President of the Royal College of Surgeons) presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, held at 12, Grosvenor Crescent, on November 12th.

Grants totalling over £20,000 were allocated for the year 1935. These included: £8,000 to the Cancer Research Department of the Middlesex Hospital; £5,000 to the Cancer Hospital (Free); £2,500 to the Cancer Research Department of St. Bartholomew's Hospital; £2,000 to Mount Vernon Hospital; £650 to the Cancer Research Department of St. Mark's Hospital; £600 to the Marie Curie Hospital; £550 to Mr. I. Hieger, working at the Cancer Hospital; £500 to the Westminster Hospital; £350 for the Radon Centre at the Middlesex Hospital (through the Medical Research Council); £350 to the Strangeways Research Laboratory, Cambridge; £300 to Dr. P. R. Peacock, for the salary of an assistant, at the Glasgow Royal Cancer Hospital; £200 to Dr. Alexander Haddow, working at Edinburgh University; £200 to Mrs. Barbara Holmes, working at Cambridge; £100 to Mr. W. S. S. Ladell, working at King's College Hospital.

The Grand Council also granted a sum of £1,750 for 1935 for the salaries and expenses of two whole-time workers, who will investigate certain important schemes of research initiated by the Scientific Advisory Committee of the Campaign. Notification was received that an allocation of £5,000 had been made to the Campaign by the trustees of the late Mr. David Shields Crawford of Edinburgh.

The French National Council of Defence against Tuberculosis has published its statistical report for 1933, with special reference to the work of the dispensaries, which numbered 820 at the end of December, representing an increase of 43 in the year. The decline in the mortality from pulmonary tuberculosis continues at a greater rate than that from other causes. There have been increases in the number of patients' attendances and of radiological examinations and treatments. Oto-rhino-laryngological examinations were fewer, however. Pneumothorax is gaining in favour steadily. Sanatorium patients totalled 19,137, and another 13,510 were admitted to institutions of the hospital type. Preventorium received 21,423, and the Grancher Foundation 4,203, of whom thirty-six were adults. Details are given in all these respects, and the activities in 1933 are compared with those of the seven previous years. A general survey is thus obtained of the progress made during recent years of the anti-tuberculosis campaign in France, with indications of changes in therapeutic outlook during the period under review.

British Medical Journal

SATURDAY, NOVEMBER 24th, 1934

THE PARLIAMENTARY SESSION, 1933-4

In the session of Parliament which began on November 21st, 1933, and ended on November 16th, 1934, legislation carried at the instance of the Ministry of Health was, with the exception of a minor Poor Law Bill, limited to emergency measures to facilitate the conservation and diversion of water during the drought and the provision of new rural supplies. Output of Statutes from the Ministry decreased pending consideration, in the session which began this week, of a further Housing Bill to prevent overcrowding and to promote the reconditioning of houses. This measure has already been in draft before the bodies which speak for local authorities. It is designed as a supplement to the national effort for slum clearance previously authorized by Parliament, and will be associated with the planning of town and country.

Public health has received little attention in either House during the past session; anxieties were expressed and reassurances given about the nutrition and general condition of people in distressed areas. Parliament is conscious of, and perplexed with, the problem of excessive maternal mortality. The Commons has learnt that the Ministry of Health has promoted special local inquiries into this. The old controversy on vaccination was scarcely mentioned; a private member's Bill for the registration of osteopaths was dropped on second reading, and the Board of Control did not come in for criticism. Generally speaking, the attitude of the House towards medicine and the medical profession varied between friendly interest and tolerant indifference. No comment was excited by an announcement made from the Treasury in July that the Medical Research Council now receives a State grant of £140,000 yearly. Behind the scenes the concurrence of a number of interested parties was gained for a draft of the Medicines and Surgical Appliances (Advertisement) Bill. A Government decision to take all the time of the House of Commons in the new session frustrates, however, the decision to introduce this as a private member's Bill. The Contraceptives Bill was carried through the House of Lords last year by Lord Dawson, but died in the Commons. A Domiciliary Nursing Services Bill also failed. Concern shown by back-bench M.P.s about the health and nutrition of school children induced a change of emphasis in Dr. Walter Elliot's Milk Act. In this was incorporated provision for more general supply of surplus milk to school children from the Milk Boards, whereas the original intention had been to dispose of

such milk for industrial use. Dr. Elliot has in preparation a Bill for reorganizing the British cattle industry. He may be able to promote, under this and the Milk Act, the reduction of tuberculosis in cattle. Other medical M.P.s had little chance of prominence. Dr. Elliot's medical colleague in the Government, Dr. J. H. Morris-Jones, has been fully occupied with his duties as a Whip. On the other side of the House, the Opposition has welcomed Dr. Christopher Addison back to its Front Bench.

Back-bench opinion in the Lords, and to a lesser degree in the Commons, compelled the Ministry of Transport to insert in the Road Traffic Act provision for a payment, through the insurance companies, towards the expenses of doctors or hospitals who treat victims of road accidents. The Act was directed to securing more safety on roads, and has been followed by experiments for protection of pedestrians, about which the Commons has lately put many questions. The claim of medical men for compensation in respect of their services to road traffic victims was admitted in the House of Lords, where Lord Moynehan and Lord Danesfort both carried Bills on the subject. On this and other matters deliberation and private negotiation by the Parliamentary Medical Committee, under the chairmanship of Sir Francis Fremantle, has been helpful both to the profession and to the Government. Sir Francis has also shaped Parliamentary opinion as chairman of the Conservative M.P.s' Health and Housing Committee. The heaviest work done by the Commons during the session was upon the Betting and Lotteries Act and the Unemployment Act. In the former the Government and House recognized that the voluntary hospitals of the United Kingdom do not wish to be supported by lotteries. A proposal to give general authorization for hospitals to hold "Christmas draws" was defeated, and provision was made to check the appeals for British subscriptions to the Dublin Hospitals Sweepstakes.

The Unemployment Bill draws a clear line between unemployment insurance benefit and the relief of able-bodied destitute persons who are not entitled to this benefit. A National Assistance Board is to fix scales of relief applicable to the whole country. The hope of the Government is that these scales, together with the restoration of the "cut" in unemployment insurance benefit, and the lowering of the age of insurance, will provide safeguards against malnutrition among the unemployed. The whole Act is a decisive stage in the break-up of the old Poor Law, and will transfer to central administration what was till lately a pauper class under the Boards of Guardians. The medical side of Poor Law work, meanwhile, is being changed by administrative action under recent Statutes. Medical men in public service were included in the restoration of half the 1931 "cut" in salaries and in the capitation fee under national health insurance. This relief was made by the 1934 Budget, and there are hints that the 1935 Budget may restore the other half.

STAPHYLOCOCCAL INFECTIONS: SPECIFIC TREATMENT

The study of the toxins produced by *Staphylococcus aureus* is one of the latest advances of bacteriology. That the commonest of pathogenic bacteria should have been the subject of important discoveries at this period of medical history is a fact which should be well assimilated by those who regard the study of ordinary bacteria as having neared the limits of its usefulness to medicine. The data we now possess are that the staphylococcus forms a toxin or toxins the chief demonstrable effects of which are the lysis of red cells, the killing of leucocytes, and necrosis of the skin: all these actions are neutralized by the serum of an immunized horse, and recovery from an acute staphylococcal infection is accompanied by an increase in the blood at least of the antibody which is most readily demonstrated—the anti-haemolysin. The nature of the toxins produced in culture finds a clear parallel in the characters of the staphylococcal lesion itself, and there is no reason for doubting that these toxins are weapons by means of which the tissues are actually attacked. There is therefore a sound theoretical basis for the therapeutic use of antitoxin, and several reports on this method of treatment have appeared.

The latest and most comprehensive of these is by C. E. Dolman,¹ who has now treated 104 cases. His serum is obtained by the immunization of horses first with toxoid and afterwards with unaltered toxin, is concentrated, and is administered preferably by the intramuscular route, intravenous injection being followed by hyperpyrexia and often a dangerous degree of collapse. The former and safer route is said to require double the dose, and as much as 600 c.cm. in all may be needed in the average severe case: one of Dolman's patients received 1,700 c.cm. The cases are placed in twelve categories, ranging from carbuncle to septicaemia, and perhaps the most significant single feature of the results is that of sixty-four patients in whom positive blood cultures were obtained twenty-nine recovered. Many of the cases are described in detail, and it is for those to whom sufficient opportunities of applying this treatment are likely to occur to study them and form their own opinions. It is notoriously difficult to furnish unassailable evidence on a question of therapeutics, especially in conditions which are by no means of everyday occurrence and which may be of such gravity that to set aside untreated control cases is scarcely possible to anyone who has faith in the treatment he is studying. Nevertheless, the experience of Dolman and others has been such that staphylococcus antitoxin demands a universal trial until its uses and their limitations have been fully ascertained. It is to be hoped that improvements in the product will obviate the need for the enormous doses now being given, if indeed these have any advantage now over a more moderate policy of dosage. Apart from the effects produced by foreign protein, and

the far from negligible question of cost, it may even be argued that the quantity of preservative (tricresol) administered cannot be without some adverse effect.

Dolman's papers refer also to the use of toxoid for active immunization, a proceeding which he recommends at an early stage in such conditions as carbuncle, when the patient is not severely ill. This is another subject, and one of which we may hear more in the near future, since the value of staphylococcus toxoid is at present under investigation in this country by the Therapeutic Trials Committee of the Medical Research Council. Of several reports already published the majority are favourable, but there is some conflict of opinion, and anomalous facts, especially in the relation between anti-haemolysin production and clinical progress, remain to be explained. Underlying this subject is an important question to which there is at present no certain answer: Is the state of resistance to staphylococcal infection dependent, either wholly or chiefly, on antitoxic immunity or on anti-bacterial? It is true that Parish, O'Meara, and Clark² have shown that immunization with toxoid confers a considerable degree of resistance to infection in rabbits, but parallel experiments with a bacterial vaccine were not carried out. Because the staphylococcus has been shown to produce exotoxin it is not therefore immediately to be classed with such an organism as the diphtheria bacillus, infection with which is almost purely a toxæmia and the issue similarly dependent on the development of antitoxic immunity. Bacteria, such as the pyogenic cocci, which besides producing toxin possess marked invasive powers, cannot be placed in the same category as this, nor can we rightly assume in the present state of knowledge that antitoxic immunity, such at least as present methods of immunization secure, is the whole of the necessary defence against their attack. It is also a noteworthy point of distinction that staphylococcus toxoid, unlike other toxoids, is being used not for prophylaxis but for the treatment of existing infections. Some of these, such as sycosis, are of a most obstinate type, and in the course of these efforts we may perhaps gain some insight into the mechanism by which chronic infections, particularly of the skin and of the mucosa of the upper respiratory tract, often resist every attempt at an active immunization which in theory should suffice to dispel them completely.

AURICULAR FIBRILLATION AND FLUTTER OF UNKNOWN AETIOLOGY

To say that a patient has auricular fibrillation is not to make a diagnosis, but merely describes the symptom—an arrhythmia resulting from some form of damage to the heart muscle. Most often this injury is rheumatic in origin; not uncommonly it results from toxic gout; sometimes it is associated with high blood pressure; and sometimes the only obvious associated lesions are the degenerations in the cardiovascular system which occur with advancing years. Rarely it appears to be connected with local infection—for example, a cholecystitis.

¹ *Canadian Med. Assoc. Journ.*, 1934, June, p. 601; July, p. 1; August, p. 130.

² *Lancet*, 1934, i, 1054.

It sometimes happens, however, that the cardiac irregularity appears as an isolated symptom, and no other abnormality is to be made out, either in the cardiovascular system or elsewhere. R. D. Friedlander and S. A. Levine¹ describe a series of twenty-five patients presenting such idiopathic fibrillation, thirteen having the paroxysmal and twenty-two the permanent form. In the former the age at onset was about equally divided in the various decades from the third to the sixth. A precipitating factor was stated to be present in some, the most frequent being exertion. Digitalis and quinidine, both alone and together, were given to five patients during attacks, and the results suggested that the treatment might have shortened the duration of the attacks. The group with permanent fibrillation comprised twenty-two patients, with one exception all males, and the average age at the onset of the attacks was 43. X-ray examination was carried out in only nine patients; in these the heart was normal in size in all except one, and this in spite of persistence of the irregularity for an average period of several years. Treatment with quinidine restored normal rhythm in ten patients; but in none of these had the onset occurred more than three years previously. One patient, for whom no attempt was made to restore normal rhythm, was stated to have had fibrillation for thirty-one years; and, although he had no treatment, he remained free from symptoms till five years before his death, when he developed a cerebral embolus. It is not stated on what grounds the original diagnosis of auricular fibrillation was made in this case, and some form of tracing is obviously desirable to substantiate such an unusual claim. Four cases of auricular flutter are also reported in men over 60 and unassociated with any demonstrable cardiovascular disease. In three it was paroxysmal, and here the exciting factor was exertion in two and an attack of lobar pneumonia in one. In one patient flutter had persisted for four years; no attempt was made to restore normal rhythm. Of the paroxysmal cases the arrhythmia was terminated with digitalis in two and quinidine in one. Auricular fibrillation is an arrhythmia which usually connotes a high degree of disturbance of the functions of the myocardium. In the solitary extrasystole or premature beat there is a harmless disturbance of cardiac rhythm which almost every individual experiences at some time or another. A more severe disturbance is paroxysmal tachycardia, but even here there is frequently no evidence of gross cardiac damage. There is reason to believe that these arrhythmias are often of neurogenic origin, and extrasystoles have been produced in animals by stimulating the hypothalamic region of the brain. Similarly, auricular fibrillation has been experimentally produced by stimulating the cardiac nerves, and it is plausible that in cases such as those described by Friedlander and Levine the alterations in auricular conductivity and refractoriness on which fibrillation directly depends are the result of abnormal nervous impulses. The role of exertion and emotion in precipitating attacks is consistent with this. Though the abnormal rhythm may be well tolerated, especially under adequate digitalization, these patients are unquestionably better off when normal rhythm is restored, and quinidine usually accomplishes this with ease,

except in cases of long duration. The grave risk of embolism resulting in the old-standing case, whether the arrhythmia persists or is terminated, is another reason for early treatment.

INFLUENCE OF HEAT AND LIGHT ON NASAL MUCOSA

It is common knowledge that in certain individuals changes in surrounding temperature produce greater or lesser changes in the freedom of the nasal air passages. A scientific study of this phenomenon by Sir Leonard Hill and his co-workers led to certain interesting results. Hill found that when rays from a dull red or dark source of heat fell on the skin of the face or body a reflex was set up which resulted in a congestion of the nasal mucous membrane and a consequent narrowing of the nasal airway. The reflex could be prevented by cooling the irradiated surface by means of a fan or by approximation of a cold surface. The rays used in the demonstration of this effect were long infrared rays. Further investigation showed that, if shorter rays were added in sufficient proportion to those coming from the dull source of heat, then the phenomenon was inhibited or at any rate antagonized. It was later stated that the effect is marked only in people with deflected nasal septa or with chronic catarrhal conditions, but that it becomes manifest in normal subjects if a slight degree of nasal obstruction is produced by a nose-clip. The antagonism of short and long waves was later extended by the demonstration that if during exposure to a heat source an electric lamp be brought near the face there is a subjective feeling of relief from heat and a sensation of relative coolness. These experiments have been examined in some detail by Winslow, Greenburg, and Herrington,² particularly those relating to the "nose-opening" effects of short waves as opposed to the "nose-closing" effects of long waves. These authors used two procedures designed to obtain quantitative data on these matters. In the first method the subject lay on his or her back in a darkened room. In one nostril a glass tip encased in plasticine was inserted so as to fit the nostril closely. This glass tip was connected to a rubber membrane tambour writing on a smoked surface on a kymograph. In this way records could be obtained of changes in pressure in the closed nostril during expiration, and hence gave a measure of any change in the degree of approximation of the mucous surfaces of the nasal airway. More accurate observation of the patency of the nasal airway was obtained by determining the time of passage of a fixed volume of air, delivered at low pressure from a spirometer, through one nostril and out at the other whilst the subject holds his breath. The inlet nostril is rendered airtight so that the circuit of the nasal airway must be made by the emerging air. This method is uncomplicated by varying respiratory activity and, according to the authors, gives reliable and consistent results. Using these methods, carefully controlled observations were carried out to test the validity of the claims made by Hill and his co-workers. It was found that constriction of the nasal airway (nose-closing) can be produced with reasonable certainty and constancy by exposure of the skin to the rays of a dark-glow

¹ New Eng. Journ. Med., October 4th, 1934, p. 624.

² Amer. Journ. Hyg., July, 1934.

radiant source of heat, by immersion of the arm in hot water, and by exposure to a high atmospheric temperature. Contrary to the views of Hill, these workers interpret their findings as due to a direct response to the warming of the skin, with no relation to any specific wave-lengths. Although these reactions are more readily demonstrated in subjects with deviation of the nasal septa or other nasal abnormality, Winslow and his co-workers, with their delicate spirometer method, have shown their occurrence in normal subjects. As regards the "nose-opening" effects of shorter wave rays described by Hill, these authors found the exact reverse—namely, an increase in nasal congestion was observed when electric light was directed on to the face of a subject already exposed to the dark-glow heater. These results appear to be supported by carefully conducted experiments, and it seems that the original observations of Hill will require re-examination before the extraordinary effects of the so-called "nose-opening" rays can be generally acceptable.

PROTECTION OF RADIUM WORKERS

The increasing use of large quantities of radium in medical practice, particularly in beam therapy, has emphasized the need for further information on the protection of radium workers from gamma rays. In a paper read before the British Institute of Radiology on November 15th Dr. G. W. C. Kaye, director of the physics department of the National Physical Laboratory (with whom were associated Mr. G. E. Bell and Mr. W. Binks) brought forward a number of observations on gamma-ray doses which have been made at the laboratory, thanks to a working association with the National Radium Trust. For α rays a system of protective recommendations has been built up on the basis of a tolerance dose, but in the case of gamma rays from radium, as Dr. Kaye explained, the position is less satisfactory, and it does not appear that enough data are available to evaluate such tolerance dose. The two main factors of gamma-ray protection are to place the radium source in as remote a position as may be convenient, and to enclose it in protective material to the greatest practicable extent. To double the distance from the source is roughly equivalent to increasing the lead protection by nearly 3 cm. But in many cases there is no alternative to lead protection, and accordingly Dr. Kaye and his colleagues have worked out the transmission curve of gamma rays in lead under conditions simulating as closely as possible those that obtain in practice. Here we must omit the elaborate tables and computations which these workers adduced, and give a brief summary of their practical conclusions. The tolerance distance for unprotected quantities of radium of 0.2 gram and upwards is greater than the distance between adjacent beds in the average hospital ward, so that discretion should be exercised if patients undergoing irradiation are placed in the same ward as other patients. As far as nurses and attendants are concerned, the tolerance distance for 0.2 gram of the unprotected element is about 2 metres, so that they should only approach within that distance when it is essential. For quantities of 0.5 gram the tolerance distance for nurses and attendants is about $3\frac{1}{2}$ metres. Therefore it is undesirable for staff to remain in the

immediate vicinity of patients undergoing treatment with such quantities. The carrying boxes used for the transport by hand of reasonable amounts of radium within the confines of hospital or laboratory are usually small and constructed of wood, both box and lid being lined with lead of about 1 cm. thickness. Such boxes are regarded by the National Physical Laboratory investigators as suitable for occasional transport of small quantities of radium, but where substantial quantities are frequently transported larger boxes with centrally situated small containers and more adequately protected should be provided, and should be conveyed by trolley rather than by hand. As for transmission by post, these investigators explored the relative merits of size and lead protection in the case of various packages containing radium which are subject to the limitations of the British parcel post (namely, maximum weight, 11 lb.; length plus girth, 6 feet), and their results showed the superiority of distance over lead protection, and that a bulky package employing no lead may have only half the weight and yet be thrice as effective as the smallest package with the maximum lead protection. The use of bulky packages in the post, moreover, is likely to result in their being transported by vehicle rather than by hand, which is an advantage. The increasing use of radium beam therapy has suggested some experiments, leading to the conclusion that nurses and attendants should not remain for any appreciable time at distances within, say, $1\frac{1}{2}$ metres behind the bomb, $2\frac{1}{2}$ metres from the side of it, or $4\frac{1}{2}$ metres in front of the bomb in the direct beam. In general, the results obtained at Teddington lend support to the recommendations of the international and British committees for α -ray and radium protection, and afford evidence that these recommendations provide a sound basis for radium protection, particularly in such matters as storage, the employment of temporary workers, and the importance of expeditious manipulation in busy radium centres.

A MENTAL HOSPITAL CLINIC

The Herts County Mental Hospital at Hill End, St. Albans, is fortunate in having a progressive and broad-minded committee which does not quibble about the introduction of the latest ideas in mental hospital work. One of the outstanding features there is the out-patient clinic, which is conducted, not by the medical superintendent, but by a visiting psychiatrist. The authorities at Hill End feel, with reason, that the position of a medical superintendent is bound up with an atmosphere of authority and discipline which makes the psychotherapeutic approach singularly difficult. To this objection is of course to be added the fact that the administrative duties he is compelled to carry out make it hard for him to find time for prolonged and patient investigation. He has an out-patient clinic at the general hospital, where he sifts out patients suitable for intensive psychotherapy, and refers them to the Hill End clinic. At the same time in-patients at Hill End attend this clinic when suited for it, and can continue their treatment there when they are discharged from certificate. The clinic is run on the team principle, and a skilled social worker from one of the London hospitals visits the patient's home and school and

acquires as much knowledge of the environmental background as possible, in order to help the psychiatrist. She is also a great help to the relatives, and is responsible for continuing this service after patients have been discharged. A psychologist makes investigations of a non-medical nature, and provides vocational guidance and educational training. Child guidance is also undertaken, and there is a playroom for observation of children. Patients are sent by magistrates, probation officers, private doctors, teachers, and social workers throughout the county. The clinic is designed to be a training centre for doctors and lay workers alike. The committee has authorized the provision of bursaries for social workers and also the appointment of two house-physicians. This provision offers a unique opportunity to the young medical man or woman who wishes to learn something about psychiatry as a preparation for general practice, but who is not willing to join a special service, with its administrative obligations and other restrictions. The house-physicians will be relieved as far as possible of administrative duties, and they will be taught how to treat the physical ailments of mental patients, and how to deal with the manifestations of mental illness which can be treated outside an institution. Their appointment will be for six to twelve months, and during that period they will also be able to attend the bi-weekly conferences of the out-patient clinic, where patients and methods are discussed.

TONSILS AND THE RHEUMATIC CHILD

The exact part played by tonsillar infection in the rheumatic group of disorders in childhood is not yet altogether clear. Dr. A. D. Kaiser, whose book, *Children's Tonsils In or Out*, attracted a great deal of notice some two years ago, has now repeated his statistical method,¹ this time dealing with a group of 1,200 rheumatic children in an endeavour to analyse the factors associated with the primary and recurrent manifestations of this disease. Because of his previous interest in the tonsil problem Dr. Kaiser's conclusions as regards juvenile rheumatism and the tonsils are of particular value, although his detailed analysis of other factors may also be profitably studied by those especially interested. It is quite generally accepted that there is a relation between an initial infection in the tonsils and a subsequent rheumatic manifestation. If this is true there should be a lessened incidence of rheumatic disease in children whose tonsils have been removed. A broad analysis in a previous study had shown that about one-third more children had their first attack of rheumatism when their tonsils were "in" than in those where the tonsils were "out." But Dr. Kaiser is not satisfied with this broad view: he is able to compute the expected incidence of rheumatic disease among the "tonsillectomized" (vile word) children of Rochester because of his previous knowledge of the distribution of tonsillectomized children at different age levels, and thus he shows that for the entire group of children the presence or absence of tonsils made only a slight difference on the frequency of an attack of rheumatism. Chorea was slightly more prevalent among the tonsillectomized children than was expected, and the same was true for muscular rheumatism or "growing pains." On the other hand, rheumatic carditis was less frequent among the tonsillectomized

children than the expected rate, and this is reflected in a still more important difference in the mortality rates. In almost comparable groups the mortality rates were 13 per cent. among the children whose tonsils were in and 7 per cent. among those whose tonsils were out at the time of the initial attack. As to recurrences, the presence or absence of tonsils appears to make no difference. It would seem possible from these results to deduce what course should be taken in the treatment of diseased tonsils in a rheumatic child. Removal will not prevent recurrences, and, in fact, it will slightly add to the risk of the child's having chorea or growing pains. On the other hand, if the tonsils are removed early in the course of the rheumatic infection there is slightly less chance of heart disease developing and considerably less risk of severe disease of a fatal type. As to age, Dr. Kaiser's present analysis makes the following point—that the advantages of removal of the tonsils to the rheumatic child are almost confined to the younger age groups, and after the tenth year the presence or absence of tonsils makes no appreciable difference.

SYPHILIS TESTS WITH SCANT SUPPLY OF SERUM

A report¹ by Dr. E. J. Wyler, which has recently been issued by the Ministry of Health, should help to solve the problem of what is to be done when it is impossible to obtain blood from a vein for the Wassermann or for a flocculation test. This difficulty is commonly met with in young children, not rarely in women, and occasionally even in men. Where a suitable vein cannot be found blood in small quantities may be obtained from various sources such as the lobe of the ear, the finger, or the heel. The author shows how with 0.15 c.cm. of serum, which is obtainable from as little as 0.5 c.cm. of blood, a Wassermann reaction and three flocculation tests for syphilis can be carried out. The tests which he has chosen are modifications of those associated with the names of Wassermann, Kahn, Meinicke, and Rosenthal: positive reactions with the Wassermann and any one of the three flocculation tests are quite sufficient to establish a diagnosis of syphilis (with the usual provisos), so that the author has made a most useful contribution to the subject. All four methods are described in detail, and their relative advantages and disadvantages are compared and discussed. With the report beside him any competent serologist could carry them out in a normally equipped laboratory.

The next session of the General Medical Council will open on Tuesday, November 27th, at 2 o'clock, when the President, Sir Norman Walker, M.D., will take the chair and deliver an address. The Council will sit thereafter from day to day until its business is concluded.

A special meeting of the Royal Society of Medicine (for Fellows only) will be held at 1, Wimpole Street, on Thursday next, November 29th, at 9 p.m., when Professor R. G. Minot of Harvard will lecture on "Some Aspects of Anaemia."

Scotland

Mental Disorder in Scotland

The twentieth annual report by the General Board of Control for Scotland¹ shows that on January 1st of the present year there were 19,538 insane persons in Scotland, exclusive of those who were maintained at home by their natural guardians. This number included 9,983 males and 9,555 females, while of the total number 2,823 were maintained from private sources, 16,638 from the rates, and seventy-seven at the expense of the State in Perth Criminal Lunatic Department. At January 1st, 1933, the total number had been 19,411, which showed an increase of 127 during the past year. Certified mental defectives on the register of the Board at January 1st, 1934, numbered 4,012, including 2,042 males and 1,970 females. Of these 1,137 were maintained in institutions for adults; 1,520 in institutions for juveniles; 1,341 in private dwellings; and 14 in the State institution. The total number of admissions of insane persons (including transfers) during 1933 was 2,862, which was eighty-one more than in the previous year, but 310 fewer than the average for the quinquennium 1925-9. Private patients admitted numbered 431, which was thirty-five more than in the preceding year, but thirty-nine fewer than the average for the quinquennium 1925-9. The number of pauper patients admitted was 2,431, which was forty-six more than in the previous year, but 271 fewer than the average for the quinquennium 1925-9. There were 359 private patients and 1,851 pauper patients admitted for the first time to establishments during 1933. Voluntary admissions are not registered, but a record is made of the names and particulars of patients so admitted, the total number in 1933 being 801, while the total number resident on January 1st, 1934, was 1,088. During 1933, 140 private patients and 923 pauper patients were discharged recovered. With regard to deaths, 200 private patients died in establishments during 1933, and 1,148 pauper patients. These figures were respectively eighteen and twenty-one fewer than in the previous year, with a death rate of 7.5 per cent. of the average number resident for the year. In the course of the year 146 patients were discharged on probation, of whom eleven were finally discharged recovered, thirty-seven returned to asylums, and three died. The number of escapes from establishments was 104; forty-eight of these patients were brought back within twenty-four hours, twenty-six within a week, and thirteen after a week, leaving twelve still absent at the expiry of the period of twenty-eight days. Accidents reported as having taken place numbered 186, of which twelve ended fatally, being due to suicide in seven cases. With regard to the boarding out of mental cases, the number of patients who were not paupers in private dwellings at January 1st, 1934, was sixty-three, while the number of pauper patients was 1,290, a decrease of twenty-eight as compared with the figure for the preceding year. Favourable comments are made upon the high standard of care bestowed upon rate-aided mentally defective patients by their guardians in private dwellings. Very few of the latter consider their duty accomplished when they have complied with the regulations by providing suitable accommodation, occupation, food, and supervision, but go much further and arouse the interest of the patients, arrange occupation for leisure time, and give them a real home. The success of the boarding-out system is attributed to the careful selection of patients and guardians, the supervision exercised by local authorities, and the interest of medical officers, although the

real success is due to the guardians themselves. It is urged also that a benefit is conferred upon the community by the presence of such patients in their midst, in so far as it produces greater sympathy and understanding among the general public and helps to develop a new and enlightened attitude towards mental illness and defect. A table shows that the proportion of recoveries in royal and district asylums averages over 30 per cent. of the number of admissions, and the significance of this relatively high proportion in recent years is connected with the fact that an increasing number of the patients from whom recoveries are to be expected now enter asylums as voluntary patients. Another factor of importance is that a number of patients suffering from early forms of mental disorder are now treated in observation wards of general hospitals, so that only the less hopeful cases are passed on to the asylums. Attention is drawn to the difficulty experienced by many patients, after discharge as recovered, and by mental defectives who have undergone a period of specialized training, in becoming reabsorbed into industry. It is pointed out that local authorities have no official duty in this matter, and that most of the after-care falls upon voluntary agencies. It is suggested it would be desirable that local authorities in urban areas should have powers to provide for the education and training of children reported as unsuitable for education in special schools or classes, and for whom, accordingly, the education authority has no duty to make provision. As an example of what might be done for such cases, there is cited a training centre established in 1930 by the local Care Committee in Edinburgh, under the charge of three teachers, which has a daily average attendance of seventy-nine. Attention is also drawn to the important work, during the past eleven years, of the Scottish Association for Mental Welfare. With regard to the financial burden of mental disease, it is stated that during the year the cost of maintenance of pauper lunatics was £932,947. The average weekly charge varied from 13s. 5d. in private dwellings to 21s. 9d. in royal asylums. The expenditure by local authorities on mental defectives for the year involved a total sum of £205,743.

Ireland

Ulster Medical Society

At the opening meeting of the Ulster Medical Society, which was held in the Whitla Medical Institute, the outgoing president, Professor W. J. Wilson, M.D., D.Sc., introduced his successor, Dr. S. R. Hunter, to the presidential chair in a happy speech, after having thanked the fellows and members of the society for their support during his year of office. Dr. Hunter acknowledged the very high honour the society had conferred on him by electing him as its president for the year 1934-5, and appealed for encouragement in his term of office. He referred to the loss the society had sustained in the past year by the deaths of Sir William Whitla, Professor Andrew Fullerton, and Professor John A. Milroy, as well as a young member, Dr. John H. Gillespie, as the result of a motor accident in London. Dr. Hunter then gave his address on his experiences during the war with the medical unit in Janesh, on the Balkan front. He handled his subject in a most interesting manner, and kept the attention of his audience throughout with a record of his impressions and experiences, dealing with illnesses rare in this country and the manner of treating them. There were interludes of exciting experiences, as well as pleasant surprises of acquaintances of more peaceful days arriving

¹ H.M. Stationery Office, 120, George Street, Edinburgh. (1s. 2d. net.)

for duty. The thanks of the meeting were conveyed to Dr. Hunter, as well as wishes for a most successful year of office.

Action Against a Public Hospital

Mr. Justice O'Byrne, in the High Court, Dublin, granted an application for further particulars in two cases in which Mr. Owen Denenny, Clane, County Kildare, was the plaintiff, and the Kildare Board of Health and Public Assistance were the defendants. In one case plaintiff sued on behalf of his daughter, aged 6½, for £3,000 damages, and in the other for £1,000 on his own behalf. Plaintiff alleged that about November 10th, 1933, his daughter was suffering from scarlet fever, and when this had been notified to the medical officer of health she was removed to the Fever Hospital at Naas, in which it was the duty of defendants to provide reasonably skilled medical and nursing treatment and attendance. He alleged that the Board failed in this duty; that they retained at the hospital a doctor and nurses whom they knew to be careless; and that they had failed to relieve the doctor and nurses of their duties in the hospital as required by an order of the Department of Local Government and Public Health. By reason of this negligence so alleged, plaintiff claimed that his daughter did not receive sufficient medical and nursing treatment and attendance, that she was discharged from the hospital and permitted to return to his house while in an infectious condition, and that she was verminous. He also claimed that his daughter infected another child, who died. Defendants denied all the allegations of plaintiff, and now asked for further particulars.

England and Wales

Ambulances for Maternity Cases

Arrangements for the free conveyance of maternity patients to hospital by the London Ambulance Service, provided to deal with street accidents, were first made in 1920, but at first such conveyance was available only during the night, except on sudden emergency and on the application of a doctor or midwife, who must accompany the case. It is now considered by the Hospitals and Medical Services Committee of the London County Council that the absence of free facilities for the conveyance of non-urgent maternity cases in the daytime is not justified, and that the ambulance service should be available without charge for such cases at all times. The conditions are that the patient shall have made arrangements for her admission to a hospital or municipal institution, that she shall be accompanied by a doctor, nurse, or female friend, and that she shall be wrapped in blankets ready for removal.

Approximately 10,000 maternity cases are admitted every year to the L.C.C. hospitals, 10,900 to the voluntary maternity hospitals, and 2,550 to the municipal maternity homes, while in the voluntary general hospitals 681 maternity and gynaecological beds are provided, giving accommodation to possibly some 10,000 patients a year. The number of cases conveyed by the Council's ambulances under the existing arrangement for night cases and urgent day cases was 4,416 in 1933. It is believed that, with the extension of service to non-urgent cases in the daytime, the probable number of cases so conveyed will be from 50 to 75 per cent. of all maternity patients, who number, as shown above, more than 30,000 a year. It is considered that at a time when every co-ordinated effort is needed to reduce the risks incidental to childbirth, and greater use is being made of municipal and other hospitals

for confinement, it is essential that no unnecessary limitations or conditions should be placed on the use of the ambulances for the conveyance of such cases to hospital. In most cases the patient does not go into hospital until labour is imminent or has commenced, and maternity patients in this condition should not be compelled to rely upon the ordinary public conveyances. Further, patients who have booked a bed in a maternity hospital have not engaged a private doctor or nurse (who, under the present regulations, must accompany them), and in many cases could not afford to do so. Possible difficulty, owing to the fear of confinement taking place in a public vehicle, must also be considered. The proposal involves an increase in the number of ambulances in commission from 147 to 153, and twenty-four additional attendants. A suggestion that daytime maternity cases might be conveyed more cheaply by taxicab at the Council's charge was ruled out, chiefly owing to the difficulty of obtaining taxicabs at certain times and in poor districts.

The Bed-bug as a Housing Problem

Dozens of live bugs were exhibited at a meeting, held to discuss the bed-bug as a housing problem, at the Royal Sanitary Institute on November 13th. They had been collected by officers of the Woolwich Borough Council, and were part of an exhibit demonstrating the life-history of the bed-bug, its place of lodgement, and methods of disinfestation. There was also a film, prepared by the lecturer, Mr. McKenny Hughes, with the aid of Mr. Leonard Day, which showed the bed-bug in its accustomed habitat, the insect feeding on the lecturer's arm, the effect of the bites, and the various steps necessary to eradicate the insect from furniture and houses. Lord Balfour of Burleigh presided at the meeting, and an appeal for a by-law controlling the sale of secondhand furniture was put forward by Mr. McKenny Hughes, who is an entomologist at the British Museum (Natural History). Prevention of infestation of new houses, he said, was not difficult. Tenants' furniture could be fumigated in transit to the new house with hydrocyanic-acid gas in one of its forms, or, alternatively, all furniture should be fumigated in the new house within one week of its arrival. The latter method necessitated a clearing place where people whose houses were being fumigated could spend the night. The disposal of material from bug-infested houses demolished under clearance orders was another difficult problem to be faced. Woodwork, as firewood and in other ways, was liable to be an important factor in the dissemination of the bed-bug. The presence of this insect should not be considered as a social stigma and something to be hidden, but as a misfortune from which any of us might suffer.

Central Midwives Board

At its November meeting the Central Midwives Board for England and Wales considered a letter from the medical officer of health for Willesden, stating that on January 1st next the Willesden Maternity Hospital would be greatly enlarged and asking that permission should be granted for eight pupils to be trained instead of five. It was agreed to reply that in accordance with the Board's practice in these matters the question of an increase in the number of pupils to be trained could not be considered until it was seen from the number of cases actually taken in the new beds that such an increase was justified. The medical officer will be asked to submit a later application when the new beds have been in use for a time. The Board stated, in reply to a letter from the county medical officer of health for Flintshire, that it saw no necessity for a local supervising authority to supply practising midwives with books of detachable pulse and

temperature charts, in addition to the ante-natal record book, approved by the Board, which contains pulse and temperature charts. The terms of the following resolution, which was passed at the annual conference of the National Council of Women of Great Britain at a meeting in Edinburgh last month, were noted by the Board:

"That, in view of the serious rate of maternal mortality and morbidity, it is desirable that more practical experience should be required of medical students and pupil midwives during their training in midwifery, and that additional post-graduate courses should be arranged for doctors and midwives practising midwifery, and all possible encouragement should be given to them to attend such courses periodically."

Approval as lecturer was granted to Dr. Beatrice Turner, Elizabeth Garrett Anderson Hospital, and Mr. Richard Glyn Maliphant was appointed examiner at the Bristol centre in succession to the late Dr. B. K. Tenison Collins. The new form of advisory memorandum, as to the drugs which may properly be carried and administered by midwives, was approved. The report on the work of the Board for the year ended March 31st, 1934, was approved as amended.

Reports of Societies

SHORT-WAVE THERAPY

A discussion on short-wave therapy took place in the Section of Physical Medicine of the Royal Society of Medicine on November 16th, Dr. J. B. BURT presiding.

Dr. W. J. TURRELL discussed the principles which govern short-wave therapy. The fundamental action of all electro-magnetic vibrations, he said, was that of a blow or impact. One of the results of the impact was the conversion of the arrested kinetic energy into heat. When diathermy was first introduced it was supposed that its results were to be attributed entirely to thermal effects, but d'Arsonval had established the fact that when administering high-frequency currents two types were dealt with—namely, currents of capacity and currents of conduction. With the former a dynamic, disruptive, or pounding action must be more in evidence than in currents which flowed freely through a good conducting medium. When high-frequency currents were applied to the human body they encountered resistance of skin and subcutaneous tissues. If these tissues were well bathed in the highly conducting fluids of the body the current would be one of conduction, but there was also set up a dispersive or disruptive action, varying in degree with the shortness of the wave-length, the energy applied, and the viscosity and dielectric hysteresis of the tissues concerned. A most noticeable feature in short-wave therapy was the very slight appreciation of heat during administration. In this way burns were more likely to occur than in diathermy, because the patient at the time did not experience heat sensation. The "burns" differed from the true heat burn of diathermy, being far more painful, owing to the induration of surrounding tissues; he had himself seen only two, but they were not uncommon. Redness of the skin following diathermy quickly disappeared, but that following short-wave therapy persisted for some time. The first was a vasodilator effect produced by heat, the second an extravasation effect caused by the pounding effects in the skin area. Surprisingly quick results were obtained by short-wave therapy; he had certainly not observed such immediate results in any form of physical treatment. Perhaps the most striking were obtained in certain varicose conditions which had shown prolonged resistance to other forms of treatment. He had successfully treated two cases of boils, and he thought short waves might be useful in some skin diseases, notably psoriasis.

Dr. A. EIDINOW related experiments to determine whether there were marked differences between the biological action of diathermy currents of above 300 metres in length and that of the ultra-short high-frequency

currents emitting wave-lengths as low as 1.9 metres. The final physiological action of high-frequency currents was heat, but it was claimed by many that, apart from heating effects, ultra-short waves had specific action on certain tissue cells and on bacteria. In his experiments he had studied the effects of ultra-short waves of 4.5 and 3.4 metres on bacteria and blood as tested on the living animal, *in vivo* and *in vitro*, and he had been unable to demonstrate any bactericidal action whatsoever with these wave-lengths provided the tissues were effectively cooled. Experiments carried out by the exposure of a suspension of living bacteria mixed with defibrinated blood had in all cases failed to demonstrate any direct bactericidal action or any change in virulence of bacteria or bactericidal property of leucocytes. The effect of ultra-short waves could be adequately explained by heat effect, varying from a temporary dilatation of the blood capillaries to massive necrosis of the tissues. There seemed to be no other biological effect.

Dr. JUSTINA WILSON said that she had used short and ultra-short waves now for about nine months. It was the character and function of the capacity current not to excite the skin and subcutaneous tissues, but to go right through all the tissues down to the depths. This was not a case of bombardment, and there was no disruption of atoms; it was a vibratory effect. She had given 500 or 600 treatments in hospital and private practice, and never had seen or heard of a burn. If a few simple precautions were taken burns were not likely to occur. So far as the heating effect went the resistance of the tissues no longer played a part in short-wave therapy as it did in diathermy. But the outstanding difference was the peculiar way in which the ultra-short waves acted on acute infective conditions and conditions of suppuration. She had found great advantage in the Pandora type of apparatus with very high energy output and continuously changeable wave-lengths of from 7 to 3 metres. The spark-gap apparatus gave insufficient power for dealing with wave-lengths of this order. Extremely good general treatment to the whole body could be given, however, with a spark machine and 15-metre wave-length—far better than general treatment with diathermy. She begged that the profession would take up this new therapy, encouraging the making in England of adequate machines, both in quality and in range; otherwise it would get into the hands of the quack.

Dr. J. H. DOUGLAS WEBSTER thought that Dr. Wilson's condemnation of the spark-gap method was premature. Having had six months' experience with a spark-gap apparatus he was able to say that certain types of cases benefited. These included fibrositis, headache and neck-ache (due, perhaps, to wind on the back of the neck when motoring), sciatica, lumbago, bladder irritability, and also, as he had stated in a letter to the *British Medical Journal* of November 10th (p. 882), those distressing colds which began with fever and depression and pain in the trachea.

Dr. MAY of Freiburg (who did not care to trust his English, and was "interpreted" by Sir Robert Stanton Woods) said that in his clinical experience of this method, which extended over four years, he had found a very pronounced depth effect depending on the wave-length, and this was even more pronounced than any surface effect. With regard to Dr. Eidinow's experimental work on bacteria, his criticism was that there had been a very arbitrary choice of wave-length (3.5 to 4.5 metres). His own experience went to show that there was not only a diathermic or heating effect, but also a specific effect.

Dr. KERR RUSSELL stated that he had given a large number of ultra-short-wave treatments. The technique was most important in such conditions as sinusitis, of which he had treated eleven cases with very good results. He had seen two burns, but in both instances he was aware of the slight mishap—such as accidental contact with the cables—which had caused them. He had treated twelve cases of boils, also with good results, and six dental abscess cases which had not shown a favourable response to diathermy, but had done well with ultra-short-wave treatment.

Dr. TURRELL and Dr. EIDINOW briefly replied, the former urging that the idea should not get about that burns could not happen: the absence or slightness of the sensation of heat experienced at the time made the treatment deceptive in this respect.

RADIOLOGICAL DIAGNOSIS OF GASTRO-INTESTINAL CONDITIONS

At a meeting of the Section of Radiology of the Royal Society of Medicine on November 16th, with Dr. F. HERNAMAN-JOHNSON in the chair, a lecture was delivered by Dr. B. R. KIRKLIN of the Mayo Clinic on "Problems of Diagnosis and their Solution by Radiological Examination of the Digestive Tract."

Dr. Kirklin began by saying that in the United States the medical profession had sought to impress the public, by broadcasting and otherwise, with the need for seeking medical counsel concerning all symptoms, however trivial, in order that malignant growths might be discovered at a time when there was a chance of cure. Speaking as a radiologist, he claimed that it was only by *x* rays, that the earliest cancerous growths of the alimentary canal could be found. Similar considerations applied to certain non-malignant growths, which could be treated with greater success early than late. He dealt in turn with some symptoms or signs which called for a thorough radiological examination of the alimentary canal. The first of these was haemorrhage, which was an urgent indication for radiological investigation. Here peptic ulcer was so often the cause that it might be the only condition considered by the clinician, but, as he showed by a series of cases, other conditions, such as a small growth in the oesophagus, might give rise to similar haemorrhage. Unless radiological examination was so carried out as to permit direct frontal inspection, small lesions of the stomach would certainly escape observation. It had always been his practice to make a complete study of the mucosal pattern after the first swallowings of barium. Bleeding from the rectum called for careful examination of the colon. In one such case by the double-contrast method—that is, insufflation of air following barium enema—a very definite polypoid growth was located at the juncture of the descending colon and the sigmoid, and proved to be a low-grade adenocarcinoma.

One of the most perplexing signs was anaemia when not accompanied by other manifestations. To discover its origin often entailed laborious investigation. In every case of unexplained or simple idiopathic anaemia a radiological study of the gastro-intestinal tract should be made. He described the case of a man of 54 whose blood picture was quite typical of pernicious anaemia, but because of the routine employed in these cases the stomach was examined, and on the posterior wall, very near the greater curvature, two very definite adenomatous polyps were discovered, which proved to be of low-grade malignancy, and the removal of which cleared up the condition. In another case, where some anaemia seemed to be the only sign, it was elicited that there was slight bleeding from the rectum. By the usual barium method nothing abnormal was visible, but the double-contrast method revealed a small, round, pedunculated polyp, which proved to be a benign lesion of the colon. With the double-contrast method it was very important to make stereoscopic films, because only in that way could these shallow defects be differentiated from the contents of the bowel. Loss of weight without any other objective manifestations of ill-health was sometimes regarded lightly by the patient, but few physicians would underestimate the gravity of the sign. It might seem illogical to give consideration to cancer of the stomach or colon in such a connexion, but actual cases proved that that was not so. The onset was insidious, and radiological examination should be among the first tests applied. In one woman who had lost twenty-four pounds in three months radiological examination showed a rather large ulcerating carcinoma in which the only symptom was loss of weight; there was an ulcerating carcinoma involving the distal half of

the lesser curvature of the stomach of a rather high degree of malignancy. Recurring vomiting without obvious cause was such an emphatic reason for radiological examination that there was no need to labour the subject, but nausea, especially when slight, was not an impressive symptom, yet it might be the sole indication of a serious condition of the stomach. In one patient with persistent nausea a very small lesion was discovered on the lesser curvature, the radiological picture including the typical meniscus sign, which was quite indicative of an ulcerating carcinoma of the stomach. On exploration a perforating lesion was found.

In patients with epigastric pain after taking food one would, of course, suspect the presence of a peptic ulcer. It was not always easy to distinguish between gastric and duodenal ulcer and between benign and malignant ulcer, and here the radiologist could be of service. In duodenal ulcer a deformity of the duodenal bulb, if constant, was characteristic. Another type of duodenal ulcer which might be overlooked was one that revealed itself under barium meal examination, when, after the barium had been pressed out, a very definite flake remained behind. This meant that there was a crater ulcer without deformity of the duodenal bulb. Workers at the Mayo Clinic now thought that in a certain group of cases they could recognize duodenitis, and differentiate it from simple duodenal ulcer. If there was a transient deformity of the duodenum, the deformity not being constant in character, and the duodenum was very irritable and spastic, the barium rushing through, and, in addition, if there was a rather fine reticular network of mucosal pattern, it was felt to be a very definite radiological picture of duodenitis. The criteria for differential diagnosis between benign and malignant ulcers of the stomach on *x*-ray examination were as follows:

Benign	Malignant
Niche usually less than 2 cm. in diameter.	Niche exceeding 2.5 cm. in diameter strongly suggests malignancy.
Niche regularly hemispherical; dense; margins sharply defined.	Niche often conical or irregular; faint; margins poorly defined.
Ulcers on lesser curvature, not over pylorus.	Ulcers on greater curvature almost invariably malignant; ulcers on posterior wall likely to be malignant; ulcers near pylorus open to suspicion.
Gastric peristalsis likely to be active.	Peristalsis often diminished or absent.
Spastic manifestations common; narrowing of antrum; hour-glass contraction.	Spastic manifestations rare.
Rugae commonly accentuated and converging towards niche.	Rugae adjacent to niche often faintly marked or effaced.
Pylorus spastic.	Pylorus gaping.
Localized tenderness over ulcer.	Ulcer seldom tender to pressure.

Dr. Kirklin went on to describe one of his errors, which had taught him much. The case was that of a middle-aged woman with a history of cholecystitis. In the course of gastric examination a definite annular defect was found radiologically. He made a diagnosis of annular carcinoma of the stomach, and because of that diagnosis and gall-stones it was thought advisable to operate. Much to his chagrin no carcinoma was discovered, but the surgeon found a definite smooth mass, which he thought was a simple hypertrophy of the pyloric muscle. In an endeavour to differentiate these conditions radiograms in a series of pyloric hypertrophies were examined, and it was found that a true case of pyloric hypertrophy had two distinctive features: (1) a slight invagination of the bulbar base, which was thus rendered concave, so that the shape of the bulb resembled that of a mushroom; and (2) a distinct cleft in the inferior border of the elongated canal, at about its middle, the anatomical basis of which had recently been established by the work of Twining of Manchester. On the basis of at least one of these two signs in combination with prepyloric canalization it had been possible to make a diagnosis in several cases. He dealt also with cases following constipation and diarrhoea calling urgently for radiological investigation of the colon; the shortness of the history here might be important. Again, cases with only indefinite peri-abdominal symptoms

sometimes showed on radiological investigation a perforating lesion on the greater curvature which appeared, radiologically at least, to be malignant. The smallest malignancy he had ever had the opportunity of recognizing was an ulcerating carcinoma 1 cm. in diameter in a man who came with quite indefinite symptoms of occasional "indigestion." In conclusion, Dr. Kirklin said that he did not wish to leave the impression that the signals he had described invariably denoted organic disease, or that x rays would invariably find it. Often the stomach sent out an alarm when the "fire" was elsewhere. If the clinician availed himself freely of radiological help he must expect to receive many negative reports; but if the findings were interpreted competently x rays gave worthy assistance.

The brief discussion, in which Professor A. E. BARCLAY, Dr. R. S. PATERSON, Dr. H. K. GRAHAM-HODGSON, Dr. G. VILVANDRE, and Dr. J. E. A. LYNHAM took part, chiefly consisted of complimentary remarks addressed to the lecturer. In response to a request to describe the technique, Dr. KIRKLIN said that the first and most important principle in colon work, whether using the ordinary barium enema alone or with air in addition, was the adequate preparation of the colon. No one would think of examining the stomach while it contained an ordinary meal, and it was just as important to make no attempt to examine the colon while it contained faeces or fluid. The most efficient method was to give the patient 2 oz. of castor oil. This was insisted upon at the Mayo Clinic, where they refused to make the radiological examination without it. A warm, normal saline enema was given next morning, and repeated flushing took place until the solution returned clear. Only then, when the colon was perfectly collapsed, was the condition considered satisfactory for examination. The barium enema was then given, and the patient was instructed to evacuate it, which as a rule he could not do completely. When he returned after such evacuation air was injected under fluoroscopic control. On such injection the patient probably again had the desire to defaecate, when he would most likely eliminate all the barium. This was repeated until the colon was completely free. The air method was not carried out as a routine procedure, but it was done in all cases of bleeding from the rectum if the other methods were negative. This examination was not as laborious as it sounded, and, on the average, when one had become accustomed to the technique, a patient could be examined in from fifteen to thirty minutes.

PSYCHOLOGY AND RELIGION

At the meeting of the Section of Psychiatry of the Royal Society of Medicine on November 13th, Dr. DAVID FORSYTH delivered his presidential address on "Psychology and Religion."

Dr. Forsyth said that modern psychology was in the best position to help in the conflict between religion and science. The light it had to throw on religion, however, did not at all serve to reconcile it to science, but rather showed more plainly than ever the incompatibility of the two. Freud had early pointed out the remarkable likeness between certain religious practices and obsessional neurosis, and had traced many sacramental rites to a common origin. Conscience had been found to take shape only about the sixth or seventh year of life, and to be based entirely on parental injunctions and prohibitions. Nor was the idea of God ever found in early childhood. A child's feeling for its father would decide the nature of its first feelings for God. The attributes that grown-ups customarily attached to God were those which had previously been experienced in the father. Children developed along one of two lines: those who gradually established their self-dependence outgrew the theistic stage, while others maintained throughout life dependence on a heavenly father. The latter line was, psychologically, a partial failure to mature. The sense of guilt and shame was also first experienced about the seventh year, arising from conflict between the child's in-

clination and the parent's wishes. There seemed to be a relation between the vast stores of guilty feeling finding daily expression in religion and the corresponding huge amount of misunderstanding and mishandling of children whereby their animal biological tendencies were checked and damaged. The less a child's guilt and shame were appealed to, the better its chance of growing up happy.

Prayer was one of the many ways of expressing a wish, and by invoking a greater authority it revealed itself as a survival of infantile dependence on a parent. The frame of mind favoured by the devout of every religion for prayer and worship seemed indistinguishable from the emotional state of auto-suggestion. Psychology had found no further evidence for the existence of a soul, but had observed that the idea arose from the implicit belief of savages in the reality of their dreams. It suggested the interesting possibility that the religious mind was essentially the child mind, incapable of discriminating reality from imagination. The reason for the almost universal belief in immortality needed accounting for, and, indeed, the idea was found also in modern science. It was as if the biological fact of immortality had come all the way through to psychological expression as a religious belief. A general relation between sexuality and religion was evident. Conversion, for example, was essentially a phenomenon of adolescence, and psychologically was no other than the new strong tide of sexual feeling being deflected into religion. The check to its usual course was the outcome of undue strictness in earlier training.

The almost universal human need to approach God through some intermediary was at first sight a strange one. Its psychological explanation was to be found in the common awe and fear of the father felt by the small boy, who preferred to go to his mother and ask her to intercede for him. Sadism was easily recognizable in religious persecution and spread of the faith by sword. Masochism was exhibited in the widespread habit of self-denial, penance, mortification, and martyrdom. The teaching of Mahomet was essentially sadistic, and that of Christ essentially masochistic. In the early days of Christianity Europe had been governed by violence, the rulers being sadism personified. Christianity had always been imposed from without and above, it being well in the interest of the rulers that their subjects should embrace such a submissive religion. At the same time Christianity eased the sufferings of the oppressed. History had no record of a time when the aggressive few were not ruling the submissive many, and Christianity had become a political force to help them.

In the concern of religion with the supernatural lay the cause of perhaps the deepest cleavage between religion and science. Infants became very familiar with what was going on in their psychic world while they were still learning their first lessons about the real world. For a time, therefore, they could only regard the psychic world as real and the outer world as part of it. Later they began to recognize the differences and the existence of two kinds of truth—psychic truth and objective truth. Infants were entirely, and children largely, incapable of discriminating between the two. At one moment a mental image took shape, and was seen as if it were outside the child; at another moment the real mother disappeared through a doorway or behind a screen. Apparition or corporeal form dissolved equally suddenly, completely, and inexplicably. The spiritual world was recognized by psychologists as another product of the fantasy-making function of the mind, which existed in all normal people, was more noticeable in neurotics, and was most marked in the insane. The whole world-wide mysterious business of gods and their worship was an example of projection on a colossal scale. The Christian Church had vigorously defended miracles against the criticism of science; this was understandable when it was remembered that in the realm of psychic reality natural law did not operate, but the miraculous was happening daily, hourly, and momentarily. The more this imaginative faculty was cultivated by the religious-minded the more familiar they must become with miraculous events. The vitalists among the scientists were mechanists as far as established science

went, and reserved their vitalistic views for unsolved problems. Their scientific sense ceased to work when confronted with the unknown. The probable explanation for such a failure of mental function was that fear had paralysed it. Fear of the unknown was one of the commonest terrors of childhood. Psychic truth, then, was an expression of the pleasure principle, and objective truth of the reality principle. Magic, religion, and science were three expressions of normal psychological activity, magic and religion appearing earlier in children, and being deeper and more primitive. Of the two, psychic truth was the more primitive, and expressed the deepest needs of the individual, and objective truth was the more highly acquired and best served in subduing the forces of nature in the interests of the individual. Neither could be disregarded, and the strife between them could not cease until both were directed to a common end. There was an antagonism between them amounting to incompatibility, and modern civilization must take its choice. Only a fraction of the total human energy available for social enterprise was being used in the service of science; very much of it was still running to waste in the interests of religion. The need was to cease pleasure-thinking, and use it in advancing science. In this way psychic and objective truth would be directed to a common end. Science alone could not satisfy.

MEDICAL LICENSING AND TEACHING IN THE PROVINCES

At the meeting of the Manchester Medical Society held on November 7th Professor J. A. NIXON of Bristol read a paper entitled "Licence to Practise and Liberty to Teach in the English Provinces."

Giving a brief description of monastic medical teaching at Monte Casino, a Benedictine monastery founded in A.D. 543, and the Arabian School of Medicine at Salerno, Professor Nixon said that organized teaching dated from the eleventh century in England, at a time when the craft guilds originated in this country and the barber-surgeons instructed their apprentices. This system of pupilage obtained for general practitioners from the twelfth century up to 1880, and for a time there existed, side by side with it, monastic medical teaching with hospital practice such as was founded in the Priory of St. Bartholomew in London. The Universities of Oxford and Cambridge, which were well established by 1209, when 300 students and professors withdrew from Oxford to Cambridge, taught medicine without hospital practice, as was the case in all universities until the foundation of the Edinburgh Infirmary in 1729. In 1363 an Act of Edward III compelled all surgeons to belong to one of the guilds (not necessarily the Barbers or the Barber-Surgeons) if they wished to practise in a town where the gild system prevailed. In 1421 medical practice was first regulated, and Henry V directed that no one should practise in physic unless approved by a university, and surgery by the Masters in that Art. In 1506 James IV of Scotland made anatomical instruction compulsory for surgeons and barbers in Edinburgh. After this time demonstrations in anatomy were the rule in the Barber-Surgeons' Companies all over England. In 1511 episcopal licences were introduced, whereby the bishops or their vicars-general examined medical practitioners, and, being satisfied of their proficiency, and in some instances of their orthodoxy, licensed them to practise. There was a singular example in 1524 of a licence granted by Thomas Cromwell, permitting "Roger Smyth, Citizen and Grocer in London, to practise physic and surgery in any part of the realm." The lecturer was at a loss to explain in what category this licence fell. In 1536 the monasteries were suppressed, and with the suppression hospital practice disappeared. During the sixteenth and seventeenth centuries the educational system was that of apprenticeship to barber-surgeons, or, in some instances, to apothecaries, for the Apothecaries' Society of London had been founded in 1617. This system consisted of apprenticeship to established practitioners, supplemented by gild lectures and demonstrations of anatomy in towns where guilds existed, but without hospital practice.

The reign of Charles II saw many radical changes. In 1662 the Royal Society was founded, and scientific study began to arouse some interest. But alongside of this birth of scientific study there were to be found instances of licences granted to mountebanks to vend medicines and practise medicine and surgery in any city, town, or borough in the kingdom. By the end of Charles II's reign the opposition to the sale of monopolies was so great that all action which could be construed as restraint of trade was held to be contrary to the public interest. Among other monopolies licensed medical practice was condemned, and anarchy prevailed. The guilds were forced to return their Charters in 1683. Thus, soon after the beginning of the eighteenth century, the Barber-Surgeons' and Surgeons' Companies ceased to attract candidates for admission. Their monopoly of practice was gone, and with it the value of their licences. The period of their demise fortunately coincided with a new impulse to found hospitals. The Restoration had meant a revival of commerce, the thinkers of the nation turned their attention to science, and both commerce and science reacted on religion. The Edict of Nantes, 1685, caused exiles from France to swarm into England and all Protestant countries. They brought with them treasures of character, as well as skill in new crafts and industries. This religious and intellectual revival was responsible for the foundation of hospitals all over the country, of which the first was St. Peter's in Bristol, founded by the Corporation of the Poor in 1696. This was not, strictly speaking, a charity hospital, although many voluntary contributions of money were given for its foundation, and Dr. Thomas Dover gave his professional services gratuitously. The foundation of many other charity hospitals followed in quick succession: 1710, York; 1719, Westminster; 1737, Bristol; 1753, Manchester. Among the promoters of these hospitals were many medical men ready to give their professional services gratuitously. From the earliest days surgeons were allowed to bring their apprentices to assist them and to receive money for teaching their pupils. This right to teach pupils at the hospitals gave such surgeons an advantage over private practitioners unconnected with any hospital. Henceforth apprentices were rarely satisfied with instruction in private practice alone. Without any force of legislation all medical students who were able "walked the hospitals," either in the capitals or in the provinces. These medical students were not as a rule the illiterate men of low social standing depicted by the novelists. The records show that they were frequently sons of gentlemen of good position, and the standard as to social position of the pupils and officials at the Bristol Infirmary was very high. Whilst opportunities for hospital study were increasing the Government made scarcely any attempt to see that medical practitioners were qualified to practise. The guilds had lost their authority. The bishops' licence was no longer required. The areas of jurisdiction of the colleges in the capitals were very restricted. Apparently the slave trade called for closer supervision of shipsurgeons, and the professional standing of many of the "African" surgeons was exceedingly high—notably, Falconbridge, whose evidence was one of the powerful factors in bringing about the abolition of the slave trade. An Act passed in 1789 required surgeons on the "African" ships to produce certificates of having passed an examination at Surgeons' Hall in London, or at the College of Surgeons of Edinburgh or Dublin, or at "some public or county hospital." Under this Act the surgeons of the Liverpool Infirmary met once a month regularly between 1789 and 1807, examining 634 candidates and passing rather less than 500. The lecturer could not discover records of any other public or county hospital exercising this right. There seemed to have been very little attempt made to license private medical practitioners. The qualification of a doctor was ability to get patients. There were obvious advantages in having studied in recognized hospitals under competent teachers, and very shortly after the revival of hospitals the hospital surgeons began to form private medical schools, where anatomy was taught regularly. There was keen competition to form these schools in the great provincial cities such as Manchester, where schools of medicine or anatomy were started.

In 1809 the Royal College of Surgeons in London was granted its Charter, and aimed at obtaining a monopoly for teaching and licensing all surgeons in the realm. It was given practically no compulsory powers, and unlicensed practice flourished unchecked. The licence of the College was optional, but the numerous independent schools quarrelled for recognition and the right to prepare candidates for examination by the College. In addition to the practitioners licensed by the Royal College of Surgeons there were many general practitioners apprenticed under the Society of Apothecaries. The apothecaries could take no fees for attendance, but could charge for their medicines. At length the Apothecaries, in 1815, obtained an Act of Parliament enabling them to hold an examination for all England and to prosecute unqualified apothecaries. The provincial medical schools then began to claim recognition to prepare candidates for the Apothecaries' examination and licence. The College of Surgeons refused to recognize the provincial hospitals as complete clinical schools, and insisted that all candidates for its examination should spend some time "walking" a London hospital. The idea of the College was to make all candidates come to London, and its opposition to the claims of the provincial medical schools was unrelenting. But the London surgeons reckoned without the Apothecaries and the powers conferred on them by the Act of 1815. In 1821 Jordan's lectures in Manchester were recognized, and the barrier against provincial teaching was broken down. The College, faced with the prospect of provincial candidates ignoring its licence and preferring that of the Apothecaries, was driven to surrender to Manchester in 1834. The open-mindedness of the Apothecaries' Society had established once and for all the provincial medical schools, but its influence was going to be once more exerted in an unexpected way. When the *Register*, set up by the 1858 Act, was opened a woman doctor, Miss Elizabeth Blackwell, made successful application to be entered on the *English Register* by virtue of her American medical degree (M.D. Geneva). This did not open the door for other women practitioners unless they could secure a medical education and a licence from some British authority. Miss Elizabeth Garrett (Anderson), having applied without success to the other examining and licensing bodies, was in 1862 admitted to the examinations of the Apothecaries' Society, and eventually obtained its licence to practise, which entitled her to be placed on the *Medical Register*. The provincial schools owed their whole existence to that society, whilst it should also be held in high esteem for throwing open the medical profession to women. In 1880 the Victoria University was the first in the provinces to receive its Charter. By a natural corollary the right to confer medical degrees was shortly (in 1883) granted to that university in Manchester. The year 1880 saw also the abolition of medical apprenticeship.

By slow degrees the responsibility for teaching and the right to license tended to be controlled by the same educational authority. The licensing corporations with no responsibility for teaching had come to the end of their useful existence. They did not now contribute in any way to the progress of medical education. But there was an increasing danger that they might multiply the issue of diplomas in special subjects in which they offered no instruction. This tendency should be very closely watched and discouraged. If specialist diplomas were necessary it was essential that they should only be issued by corporations which accepted responsibility for giving instruction. Some of these diplomas were issued by universities which could offer facilities for study in particular branches of medicine. Such courses of study might well be encouraged. On the other hand, there were others issued by what must be designated as educationally irresponsible bodies. The time had come, in Professor Nixon's view, for irrevocably combining the licence to practise with the liberty to teach. The privilege of educating recruits to our profession was more important than the responsibility for examining and licensing.

The address concluded with a quotation from a sermon by Dr. Dell, who was Cromwell's chaplain, and was intruded at the Commonwealth as Master of Gonville and Caius College. He was the first to suggest that there

might be other universities than those of Oxford and Cambridge. "Doubtless it would be more suitable and more advantageous, to the good of all the people, to have universities or colleges, one at least in every great town or city in the nation, as in London, York, Bristol, Exeter, Norwich, and the like. . . ."

THE ALLERGIC STATE

At a meeting of the Pathological Society of Manchester on November 14th Professor O. C. W. PRÄUSNITZ discussed "Idiosyncrasy."

Dr. Präusnitz said that case-histories of urticaria, asthma, and digestive hypersensitivity demonstrated the general uniformity of the chief symptoms, which, no matter what the exciting cause, were fairly independent of the particular tissue affected. This was well illustrated by researches on hay fever. The fundamental work was carried out by Blackley of Manchester, who, himself a hay fever patient, in 1873 described the characteristic features of the malady and cleared up its aetiology; he also found the way to prevent the onset of the attacks. Dunbar and Präusnitz studied the aetiological agent of the disease, and prepared an antiserum, which was shown to act not as an antitoxin, but as a kind of cytolytic. Comparison of this and kindred diseases with anaphylaxis had led the speaker to demonstrate in the serum of hypersensitive patients a substance which transmitted the sensitive condition to normal persons. The chief feature of the test—the Präusnitz-Küstner test—was to inject intradermally 0.1 c.cm. of the patient's serum into a normal subject, and to inject into the same spot on the following day 0.1 c.cm. of a suitable dilution of the causative agent. A local urticarial reaction developed: there was no danger of general sensitization to the person subject to the test. This method was applicable to many forms of hypersensitivity. The aetiology of hypersensitivity was twofold. (1) The attacks were brought on, probably in every case, by a specific agent. The specific antibodies in the patient sensitive to this agent would liberate from it some decomposition product, perhaps Oriel's P-substance, which caused the lesions. (2) The liability of certain persons to produce such antibodies must depend on a constitutional factor, which in many cases was inherited. Treatment was directed against the agent by desensitization with the specific substance or non-specific substances—for example, peptone. General measures served to lower the vagal hyperexcitability present in most cases; this was sometimes achieved by the administration of calcium preparations.

COCCYGEAL SINUS

At a meeting of the Liverpool Medical Institution held on November 8th, with the president, Dr. J. MURRAY BLIGH, in the chair, Mr. J. B. OLDHAM read a short paper on "Coccygeal Sinus."

Mr. Oldham reported a series of twenty-three cases of coccygeal sinus seen since 1933, fourteen of which were in female patients. Twenty were infected when first seen. Of these nineteen were excised and the wound sutured, and primary union was obtained in all. Mr. Oldham considered that if primary union was to be obtained there must be asepsis or adequate antisepsis, avoidance of post-operative infection from the anus, complete haemostasis, avoidance of buried absorbable sutures and ligatures, obliteration of the cavity left after excising the sinus, and the use of an everting stitch that would overcome the tendency of the skin edges in this region to turn in. The patient was prepared as for haemorrhoids, and after the operation fluids only were given; in this way the bowels are kept unopened for six to eight days. A wide elliptical incision was made down to the sacro-coccygeal ligaments. Haemostasis was secured by *forcipressure* and hot packs. The cavity was obliterated by deep sutures—usually six—of silkworm, which passed through all the thickness of the tissues in the edge of the cavity

left after excision, and also took a bite of the ligaments in the dorsum of the sacrum. Mr. Oldham noted that in eighteen of his cases there were secondary sinuses, and of these fourteen opened on the left of the mid-line. In only one case had a correct diagnosis been made before the case was referred for consultation. This failure to make a correct diagnosis Mr. Oldham considered natural, as in only one of the standard English textbooks of surgery was coccygeal sinus even mentioned.

Spinal Tumours

Professor HENRY COHEN read a paper on "Hour-glass Tumours of the Spine." He said that in a series of fifty cases of compression paraplegia due to tumours of the spinal canal he had observed three cases of so-called hour-glass tumours which merited separate clinical description, because, despite their varied pathology, they displayed characteristic features which gave rise to special problems, both in diagnosis and in treatment. Professor Cohen confined his detailed records to those cases having extradural and intradural masses joined by a narrow pedicle passing through an enlarged intervertebral foramen. He emphasized that any level of the spine was a possible site for such a tumour which might arise from nervous, fascial, osseous, and other local tissues. These tumours displayed the usual symptomatology of spinal compression with corresponding changes in pressure and chemistry of cerebro-spinal fluid, but additional features which merited emphasis were: (1) the frequent and severe root pains which resulted from the situation of the tumour; (2) the presence in the cervical, and occasionally in the lumbar, region of a palpable mass; and (3) pain on movement of the spine, rigidity, etc., arising from the vertebral damage. The x-ray picture was in most cases typical, though commonly interpreted as tuberculous disease of the spine with secondary abscess formation. In order to prevent recurrence of the tumour, both intraspinal and extraspinal portions must be removed, the primary attack being on the intraspinal portion. In the discussion which followed, Dr. G. S. SWAN said that in a case under his care the first symptom was severe pain along the course of a nerve, which Professor Cohen had stressed as an important point in the differential diagnosis. For about six months before the onset of pressure symptoms the patient had severe "neuritis" of the left arm. Pressure symptoms arrived suddenly and affected the leg arm and leg. He was then seen by Professor Cohen, and later operated upon by Professor Kelly. Convalescence was uneventful, and, except for slight paresis of the left arm, relief of symptoms was complete. The patient had been at work at his old job as a labourer, carrying heavy loads, for over two years. He stated that he was quite well, and able to do the heaviest work. There was no trace of any paresis, and recovery seemed complete.

WILLETT'S FORCEPS IN PLACENTA PRAEVA

At a meeting of the North of England Obstetrical and Gynaecological Society held at Liverpool on October 26th, with the president, Professor DOUGAL (Manchester), in the chair, Mr. C. H. MARSHALL (Liverpool) read a note on "Willett's Forceps in Placenta Praevia."

Mr. Marshall said that this method was introduced in 1925 by the late J. Abernethy Willett. He considered that the simplest means of controlling bleeding in cases of placenta praevia was to puncture the membranes and make downward traction on the presenting vertex by means of Martel's scalp forceps, which had since been modified and called after him. The method involved minimal handling, and consequently less risk to the mother and a better chance for the baby. No large series of cases treated in this way had been reported, although the principle has been used sporadically in this country and elsewhere. At Liverpool Maternity Hospital between 1926 and 1931, 170 cases of placenta praevia were treated either conservatively or by podalic version or Caesarean section with fourteen maternal deaths (8.2 per cent.).

Less than 12 per cent. of the babies of the cases treated by version survived. In 1932, 1933, and the first ten months of 1934, 118 cases had been treated with four maternal deaths (3.4 per cent.); 50 per cent. of the babies of the cases treated by Willett's forceps survived. The use of Willett's forceps was introduced in 1932, and an increasing number of cases had been treated by it, with a corresponding decrease in the number of versions. The percentage of cases treated by Caesarean section in each year had remained about 20.

As regards the method of application, the lithotomy position was desirable but not essential. Anaesthesia was not used in a very anaemic patient; indeed, it was often omitted in multiparae. It was important to remove any clots present from the vaginal vault; this could be done simply by inserting a Sims's speculum along the posterior vaginal wall and then depressing the vulval end. An assistant fixed the head; two fingers were passed into the vagina, and one or both, according to its dilatation, through the cervix. A point was sought where only membranes intervened between the head and the examining finger: this was most likely to be in front, as the placenta was usually found on the posterior wall of the lower segment. The membrane hook was guided along the fingers and the membranes scratched through against the head. Without withdrawing the fingers, the forceps was similarly guided in, opened, pressed firmly against the scalp, and closed. The grip on the scalp was tested by traction, which should control any haemorrhage at once; before the fingers were withdrawn. A cord carrying a pound weight over a pulley at the foot of the bed was attached to the handles of the forceps. If anaesthesia had been used the tension should be controlled with the hand until vomiting had stopped. The forceps was removed when the head had descended completely into the pelvis.

In Willett's method anaesthesia might often be omitted; the manipulations were gentler, less blood was lost, and less liquor escaped than during a bipolar version. The disadvantages of a breech presentation, especially in a first pregnancy, were avoided. Version tended to be used in cases of complete placenta praevia, and this partly accounted for the high foetal mortality. If a de Ribes bag could be inserted easily the forceps could be applied still more easily, and with better results.

Vaginal packing was a bad method, owing to the high incidence of sepsis. It was generally used if the os was closed or nearly so; if there was, as there almost always was, room for one finger and the forceps to pass through the os, the forceps might be applied. When the forceps was applied against the most accessible part of the head and the jaws were closed, a ridge of scalp was raised. If traction was now applied a wider area of scalp was drawn out in the form of a cone, the apex of which was drawn into the internal os; in this way pressure was made on the bleeding surface and haemorrhage at once checked.

In connexion with the indications for its use, Mr. Marshall said that the vertex must be presenting. If the breech was downwards, external cephalic version could be done and the forceps applied, but this was not recommended; it was simpler to bring down a leg. With a transverse lie it was probable that the placenta praevia was complete. With a complete placenta praevia, owing to the profuse haemorrhage which might accompany any vaginal procedure, the mother's interests were often best served by Caesarean section. In an emergency it was probably easier to burrow with the fingers through the placenta and grasp a foot than to apply the forceps to the scalp of a head which was difficult to fix and perhaps even to bring to the middle line. In disproportion, which was seldom met with in these cases, owing to the frequency of prematurity, Willett's forceps was contraindicated. Rarely, the forceps lost its grip and came off before fulfilling its purpose, and this necessitated reapplication or some other form of treatment. It occurred most commonly if the scalp became macerated. On applying the forceps it was important to ensure that the amount of scalp grasped had completely and evenly filled the

of the instrument. Other disappointments were usually due to factors common to all methods of vaginal delivery in this condition; not infrequently the foetus died *in utero*.

In conclusion, the speaker summarized his observations as follows: (1) Traction on the scalp perfectly fulfilled the greatest of its aims—the control of haemorrhage. (2) Fewer mothers would die and more babies would survive if this method were more widely used. (3) The method was simple and could be more easily carried out than bipolar version. (4) No attempt was made to compare it with Caesarean section, which had its own special sphere of usefulness in the treatment of this condition.

Other Matters

Mr. J. ST. GEORGE WILSON (Liverpool) read a note on "The Aschheim-Zondek Reaction in Genital Tuberculosis." He concluded that this test was commonly positive in association with tuberculous salpingo-oöphoritis; that the presence of a positive Aschheim-Zondek test associated with amenorrhoea when pregnancy could be excluded was suggestive of tuberculosis; and that the presence of a modified Aschheim-Zondek test might indicate healing or retrogression of genital tuberculosis, especially if it had been previously positive. Mr. P. MALPAS (Liverpool) described a case of hypersexuality associated with cystic ovaries treated by partial ovariectomy. Dr. J. W. BRIDE (Manchester) described a case of adenocarcinoma of the corpus uteri associated with squamous carcinoma of the vagina. Dr. C. H. WALSH (Liverpool) described a case of actinomycosis of the ovary, and showed a specimen of tubal chorion epithelioma.

CORRESPONDENCE

Elections to G.M.C.

SIR,—May I have the courtesy of your columns to express my thanks to the registered medical practitioners of Scotland for the renewal of their confidence in their direct representative on the General Medical Council.—I am, etc.,

Edinburgh, Nov. 15th.

NORMAN WALKER.

Bacteriological Examination of Milk

SIR,—Dr. J. B. Howell, medical officer of health for Hammersmith, has drawn attention, in the *Journal* of November 10th (p. 882), to the great variation in the laboratory reports he has received on samples of milk submitted for bacteriological examination. I am sure he has not overstated the difficulties, administrative and otherwise, of the present situation.

It may interest your readers to learn that three years ago, with the aid of grants from the Empire Marketing Board and from the Ministry of Health, an investigation was commenced in this school into the technique of the bacteriological examination of milk. Professor G. S. Wilson has been in charge of the work, and has had the advice of a strong consultative committee, consisting of members appointed by the Ministry of Health, the Ministry of Agriculture and Fisheries, the Department of Health for Scotland, the National Institute for Research in Dairying, the Society of Medical Officers of Health, and the London School of Hygiene and Tropical Medicine. It is expected that a full report on the results of the investigation will be published about the middle of next year.—I am, etc.,

London School of Hygiene and
Tropical Medicine, Nov. 13th.

W. W. JAMESON.

London University and its Medical Schools

SIR,—As a member of the Court and of the Senate of the University of London I have been impressed by the very small proportion of students studying at London medical schools for a London degree who actually complete their course and proceed to a degree. That this ratio is indeed glaringly small will be evident when I mention that in one recent instance a medical school reported in a certain year thirty-three students as following courses for the London medical degree, but only one actually graduated. When we consider the very large sum—over £100,000 for the current year—which the Court of the University distributes as grants to the medical schools of London such a result cannot fail to be disappointing.

It has been explained in various ways at interviews which the Court has held with the medical schools; the principal reason given has been that owing to economic stress students have been obliged to enter practice with lower qualifications than the degree, and have been unable to wait to take the degree itself. They have thus wasted, as regards any university recognition, several years of education of the highest university standard, and their position is all the more galling as London University students at the medical schools meet with large numbers of students who come for their clinical training from the older universities to the medical schools. These students come to London with a degree (usually B.A.), from their university as a result of three years' study in medical sciences, whereas the London University student, after three years' equivalent study, achieves only the second M.B. examination, which is of an intermediate and not a degree status, although the subjects and the level of attainment in them are entirely comparable with those which qualify for a B.A. degree at the older universities. Statistics supplied by the schools demonstrate that the majority of students entering for the London degree pass the second M.B. but are unable to stay the course for the third examination. The London University student is thus obviously handicapped as compared with his fellow-student from the older universities. This is a grievance of old standing, and I submit that the time has come to rectify it in the interests both of the students themselves and of the University, which is deprived of large numbers of students who by the standards of the older universities would have taken a degree. This would be an advantage to the student, even though he failed subsequently to achieve the qualifying examination of M.B., B.S., and the reform would incidentally remove the reproach that the London medical schools produce very few actual graduates of London University.

The remedy I propose is that the Senate should institute a new degree in the Faculty of Medicine, which might have the name of "Bachelor of Medical Sciences," attainable after a three years' course of study. This name is suggested to me by my recollection of the effort made some thirty years ago to found an "Institute of Medical Sciences," which would have covered all the subjects leading to the second M.B. examination, but the name adopted is a secondary consideration so long as it involves a degree. This degree would be a degree in the Faculty of Medicine as the Bachelor of Pharmacy now is. It would take the place of the present second M.B. examination, and would, of course, not be a registrable qualification to practise medicine. To give this degree a standing comparable with the other degrees of the University the standards of the first and second M.B. examination would, where necessary, have to be raised to the level of the intermediate and final examinations in other faculties. Such an adjustment would not be difficult, and the

stiffening of the earlier examinations would not in the long run hurt the student, who would find out his weakness before wasting time upon a hopeless task.

I submit this proposition for consideration by the teachers in medical schools of the University, who are primarily interested in the matter, and this letter is written in the hope of eliciting their views.—I am, etc.,

House of Commons, Nov. 16th.

E. GRAHAM-LITTLE.

A Plea for Abolition of the Pelvimeter

SIR,—One of the chief aims of ante-natal examination is to estimate the size of the pelvis, in order to prevent the risk of difficult labour due to disproportion between the size of the head and the capacity of the pelvis. This is done chiefly by a system of external measurements which might, at first sight, be assumed to provide an idea of the absolute size of the pelvis. I am going to suggest that reliance placed upon this method of diagnosis is liable to lead to a large amount of unnecessary inductions of labour and Caesarean sections, and is therefore not only useless but actually dangerous.

Let us ask ourselves a few questions:

1. Is it possible to obtain accurate and comparable readings of the measurements of the external bony points in the living subject? The bluntness of the bony points and the variable covering of fat make it impossible to be accurate within a quarter or even half an inch. Experienced people measuring the same pelvis will usually obtain different readings. A variation of half an inch in an external diameter is within the limits of error, and yet if that half-inch be transferred to an inference of the internal diameter it might seriously influence opinion on the diagnosis of contraction.

2. Do the external measurements, even supposing they can be accurately made, bear any useful relation to the size of the pelvic canal? If we are to infer that the size of the canal is reflected by external measurements sufficiently exact to be of clinical value, then the bony walls of the pelvis must be of substantially the same thickness in all women. But we know this is not true. Further, by external pelvimetry we infer that the distances between the iliac plates, as measured by the intercrural and interspinous diameters, must be closely associated with the size of the true pelvis, which again is not true. It is a common clinical experience that internal palpation of the pelvis, and also often a subsequent normal labour, belie the inference made from reduced external measurements, and, conversely, that difficult labour due to disproportion sometimes follows in women who show normal measurements.

3. Does the absolute size of the pelvic canal within the comparatively narrow limits of the great majority of women have much influence on labour?

4. Are we not liable to stress the importance of contracted pelvis as a cause of difficult labour rather than recognize the much greater frequency of inertia, wrong position of the child, incomplete flexion of the head, and rigidity or spasm of the soft parts?

Experience of labour leads me to believe that too much stress is laid upon disproportion and not sufficient attention is given to other factors. Believing, therefore, that the pelvimeter is unreliable, I would submit, further, that not only is external pelvimetry useless, but that it is positively harmful. Either because measurements cannot be accurately read or because fallacious deductions are drawn therefrom, it commonly happens that a diagnosis of contracted pelvis is made when there is nothing more abnormal than a reduction of the ample pelvic reserve. But, nevertheless, the diagnosis of contraction is made and the woman is advised to have either induction of labour or Caesarean section.

It has been shown by Holland and others that the vast majority of inductions of premature labour for contracted pelvis (or disproportion) are unnecessary, if judged by the

subsequent easy spontaneous labours; while, on the other hand, induction by bougies is not without risk. Of 533 septic patients admitted during two years to the isolation block of Queen Charlotte's Hospital 7.3 per cent. are described under aetiology "following induction." Induction of labour is commonly regarded as a trivial and harmless interference; but this is not so, for in addition to its role in the production of sepsis it bulks largely in the aetiology of severe inertia. In forty-nine cases of true and severe inertia (mortality 10 per cent.) induction was performed thirteen times (26 per cent.). Caesarean section performed unnecessarily for a wrong diagnosis of contracted pelvis is even more liable to be followed by misadventure, including not only a mortality risk of 1.6 per cent. (Kerr and Holland), but also later sequelae of various forms. If, therefore, delivery is made by Caesarean section the woman is subjected to a risk four times as great as that of normal labour. This increase of risk is incurred for the woman under consideration largely because of a wrong impression of the size of the pelvis based upon the use of the pelvimeter.

Any measure which will reduce interference in labour, including induction and Caesarean section, and will increase the number of spontaneous labours, will contribute largely to the reduction of maternal mortality. Let us abolish, therefore, the misleading pelvimeter, and in its place rely upon a diagnosis based upon the internal examination of the pelvis, the sacrum, the lateral walls, the subpubic angle, and the "knuckle test" of the width of the ischial tuberosities. In other words, let us examine with our finger the canal through which the child must pass. The final decision must rest upon the capacity to push the head into the brim, though the more experience I have the more I rely upon the internal palpation of the pelvis than upon the relation of the head to the brim. It is said that the best pelvimeter is the child's head; I would rather say that it is the instructed finger making a digital examination of the pelvic basin and outlet.

I have taught and used the pelvimeter for many years, but I feel that it is time to reconsider our ante-natal methods, in view of the increasing death rate. A contribution to this stocktaking is a plea to revise our ideas of "disproportion," which can best be done by abolishing the pelvimeter.—I am, etc.,

London, W.1, Nov. 17th.

ALECK BOURNE.

Puerperal Morbidity and Mortality

SIR,—It would seem from pronouncements in both lay and professional press that we are in for another drive in connexion with puerperal morbidity and mortality. I think it would be valuable, therefore, if we might survey the whole situation from ten years ago, when Professor Munro Kerr launched his first diatribe on the mortality attending childbirth. It will be remembered that the general practitioner was blamed for the high mortality and morbidity rates, and that Professor Kerr advised then that all midwifery in Glasgow should be in the hands of twelve specialists, with ample hospital bed space to fall back upon. It was pointed out then that Professor Kerr's scheme would prove a futility and an expense for the following reason.

The morbidity and mortality rate was heaviest in hospital. It was also as heavy in the private practice of the consultant as it was in the poorest general practitioner practice. Such a position was a greater reflection on the work of the consultant class than it was on the general practitioner class, for in the former, with every facility that money could procure, their returns were as poor as those of the general practitioner, who had to produce his

results under all conditions of poverty, dirt, and degradation. Such a position rendered it an impertinence of the consultant class to ascribe the blame to the general practitioner, and an added impertinence to suggest that this work should be taken from the general practitioner owing to his incompetence and transferred to hospital and specialist attention. Their record made it a certainty that at the very best there would be no fall in morbidity and mortality rates.

It was pleaded ten years ago that before embarking on all this expenditure of public money a lesson might be learned from the records of those general practitioners and nurses who had proved themselves able, year after year, to attend hundreds of midwifery cases with a morbidity and mortality that were practically negligible. All to no purpose. To-day we stand amazed to see the colossal expenditure—largely futile—that has resulted from attempting to put into execution the ill-digested schemes of the powers that be. The situation is a veritable puerperal Passchendaele. Here in this city of Glasgow the effect of all this ramp has been to put midwifery upon the rates. The general practitioner has now practically no midwifery, and some midwives have had to draw parochial relief owing to their cases being hospitalized over their heads. Nevertheless, in the forefront of the experts' programme is the slogan that the general practitioner and nurse should return frequently to hospital for refresher courses in the subject that they are now no longer allowed to treat.

Ante-natal care was to solve all our difficulties. So it might if these centres had been properly staffed with experienced men. Here in this town we offered a general practitioner service in ante-natal work to the public health authorities only to have it turned down almost with contempt. It was made abundantly plain that the public health authorities did not desire our help on any terms. Meanwhile the morbidity and mortality rate goes merrily upwards. Colossal sums have been and are to be spent, while the unprecedented propaganda in the lay press, in which professors and politicians vie with each other in creating scare lines, steadily convinces the wives that caution is best; and the birth rate falls continuously except among the careless, the reckless, and the ignorant. There is still time for reason to prevail, to cut our losses, and to return to a study of the methods of those general practitioners and nurses who have demonstrated over long terms of years that midwifery can be made as safe as defaecation.

It may astonish Dr. G. W. Theobald (*Journal*, November 10th, p. 850) when I say that the methods which he has discovered give the best results are precisely those that have been in use among general practitioners for a quarter of a century.—I am, etc.,

Glasgow, Nov. 12th.

JAMES COOK, M.D.

SIR,—It is perhaps impertinent for a physician who has had no practical experience since his student days in midwifery to intervene in a discussion upon maternal mortality, but may I suggest that obstetric surgeons should consider whether a change in the traditional position during labour and in the subsequent lying-in period might not materially reduce the liability to sepsis. The usual lateral position is surely not conducive to efficient drainage, whilst the dorsal, with the shoulders well raised, would mechanically assist labour, lessen the liability to laceration, and materially hasten the elimination of discharges, in addition to rendering the douching of the parts easy and effectual.—I am, etc.,

H. J. CAMPBELL, M.D., F.R.C.P.

Dartmouth, Nov. 19th.

Obstetric Methods at St. Mary Abbots

SIR,—While congratulating Dr. G. W. Theobald on his report in your issue of November 10th, I would like to challenge his statement that "the morbidity rate was, it is believed, the lowest recorded by any hospital in this country." In the *British Medical Journal* of August 16th, 1924, he will find the records of the Louise Margaret Hospital, 1920 to 1923, reporting 1,850 consecutive maternity cases with three maternal deaths. This is less than half his death rate of four maternal deaths in his 846 cases. Yet at the Louise Margaret Hospital operative intervention was higher—eight Caesarean sections as against his one, and 7 per cent. forceps rate against his 3.5 per cent.

The 1,850 cases had all been seen ante-natally by me with the exception of four, two of which were emergency cases that were fatal. He will find full particulars in the paper I read at Bradford before the British Medical Association. Non-intervention can be carried too far, and I have come to believe that possibly those obstetricians who condemn Caesarean section so loudly do so because their own surgical results have not been so good as those of their more surgically spirited colleagues. I have seen worse damage done with forceps than with Caesarean section, and probably some of the unnecessary Caesareans that are done would fare worse with forceps in the same hands. Statistics, however, are often fallacious, and a few concealed accidental haemorrhages will convert pride into humility, as was my experience later on.

I agree most emphatically with Dr. Theobald that at least three years' continuous practical work and at least 1,000 cases alone fit a man to supervise and offer sound judgement in obstetrics. If the public would turn their attention from criticizing the doctors and nurses, and see to it that the Government and administrators provide a real maternity service for the country, officered by men of obstetric experience, with diplomas of the College of Obstetricians instead of by medical officers of health with the diploma of public health, which has nothing to do with midwifery, better results might be expected. Would the public be surprised if the target was never hit by the guns of its Navy and Army if the artillery were officered by the infantry? Nature exterminates mothers who are bad reproducers. It is pretty wonderful what we achieve in our fight against Nature when you think of so many of the mothers we are expected to rescue from her attempt to improve the race. We will never reach perfection, but if the public think it worth while saving a higher percentage of mothers' lives they must pay for it pretty heavily in cash, and this is not popular. What we might save in mothers and babies will soon be killed off on the roads.

Dr. Theobald seems to advocate a return to old methods that have been tried for years and failed to satisfy us. I prefer to try and advance, profiting by the exhaustive bacteriological work that has thrown light on epidemics of puerperal sepsis, and hence I like masks and dettol at present. But here is an interesting point. He maintains that the normal temperature—98.4° F.—is pathological in the puerperium. To explain this, I have read his routine very carefully, and wonder if it is the war Le wages on the alimentary canal that gives rise to this idea. On admission, two ounces of castor oil, then an enema, and another two ounces of castor oil the day after delivery, followed by a purge every night that the mother is in hospital. I am director of a unit where bed-pans are automatically cleaned and then boiled. I take it there would not be much time for this in his unit, and that is why they are flushed and the rims rubbed with pure lysol. Pure lysol is uncomfortable if it reaches certain

parts of the anatomy. But during acute diarrhoea it is difficult to push the temperature up to 96° F., let alone 98.4°.

But the thing that interests me more than all the rest is in his rules for the nursing staff. He says: "A further enema is given towards the end of the second stage." I prefer light anaesthesia, and surely the mothers would too; but is the nozzle introduced also with forceps, for he forbids the fingers to touch the patient's perineum at this stage? Is it true that this method of keeping the bowels in a free state originates in Ireland? Does not the author call it the "Modified Garden of Eden"? Where is the analogy? It leaves me still guessing.—I am, etc.,

London, W.1, Nov. 13th.

E. LAWTON MOSS.

Professor Briggs

SIR,—It is proposed to place a bronze plaque on marble base in the museum of the department of obstetrics and gynaecology, University of Liverpool, to signify that the department was founded by Professor Henry Briggs. It is thought that some old students and other friends may wish to contribute towards the cost, which will be from £80 to £90. Intending subscribers should communicate with J. St. George Wilson, F.R.C.S., 11, Rodney Street, Liverpool, stating what they would like to give. No contributions should be sent as yet.—I am, etc.,

Liverpool, Nov. 19th.

J. HAYWARD WILLETT.

Dilating the Cervix in Placenta Praevia

SIR,—I do not think W. J. Young's statement (*British Medical Journal*, November 10th, p. 884), on dilating the cervix in placenta praevia, should pass without comment. Recently, in recording fifty cases of placenta praevia I have attended in the past six years, I came across the records of three cases attended by other doctors that terminated fatally. In each of these cases the cervix had been manually dilated to allow internal version to be performed, and in one of them the practitioner wrote to me that he had carried out the dilatation and internal version without anaesthesia. This woman arrived at the hospital in a state of extreme collapse suffering from profound shock, and in spite of every effort to combat the shock died suddenly a few hours later. After the internal version there had been no further vaginal haemorrhage. In the other two cases there had been a number of vaginal haemorrhages spread over a period of days prior to admission. Both died from shock after manual dilatation of the cervix and internal version had been performed.

I would stress two facts now recognized by most obstetricians: (1) That haemorrhages in pregnancy, especially after the twenty-eighth week, render the patient peculiarly liable and susceptible to surgical shock. (2) That the obstetrical manoeuvre of manual dilatation of the cervix, more than any other, causes severe shock. So that to dilate manually the cervix in a patient who has had one or more haemorrhages is to invite a fatal termination from shock. The statement "if placenta is detached from uterine wall as far as the finger can reach" contains advice to a line of treatment fraught with great danger. I would point out that:

1. With the patient in the lithotomy position it is possible in many cases of so-called central and marginal placenta praevia to separate more than half the placental attachment from the wall of the lower uterine segment with the finger introduced through the internal os. This would engender severe bleeding, and would add to the surgical shock of manual dilatation of the cervix that of

obstetric haemorrhage. (I have seen severe haemorrhage follow vaginal examination performed clumsily by a midwife, with blood spouting from the vulva with each cardiac pulsation. She had detached a small lobe as big as a two-shilling piece, into which a large placental vessel passed.)

2. Such a manoeuvre, by further placental detachment, must add to the foetal mortality which is already appalling in placenta praevia.

3. Digital interference with the placental site would add to the risk of sepsis, which is well known to be considerable in these cases. The statement "the whole hand should be passed into the uterus... the child turned and slowly delivered" contains a piece of advice which is not in keeping with the accepted practice of our best obstetricians.

I would further point out that:

1. After manual dilatation and internal version it would be best to allow the patient to deliver herself later, after she had recovered to some extent from the shock and haemorrhage.

2. However slowly the delivery is effected consecutive on internal version, further manipulative intervention required for extended arms and the after-coming head is in a number of cases inevitable, with the immediate consequence of added shock to the patient.

3. Full manual dilatation of the cervix could not be attained without grave risks in this condition, and even "slow" delivery through an undilated os entails a degree of added shock, which is to be avoided in the treatment of placenta praevia.

The last statement that "... very great prior loss of blood may entail more rapid delivery" contains the germ of very unsound teaching. The patient, shocked and exsanguinated by the haemorrhage of placenta praevia, is in no state for delivery at all. Surely the bleeding should be stopped by the safest possible methods (preferably that of Braxton Hicks) and every immediate effort expended to combat the shock. Some hours later the delivery would be effected with at least a small margin of safety. In this I offer no criticism of Mauriceau's heroic effort to save his dying sister, but point out to practitioners some possible dangers in the treatment of placenta praevia at a moment when the problem of maternal mortality is being reviewed with much anxiety.—I am, etc.,

J. STANLEY COLEMAN, M.B.,

Forest Gate, E.7, Nov. 12th.

B.S. Lond., M.R.C.S.

The Duodenum and the Kirby Grip

SIR,—New fashions have a way of setting up some curious by-products, and sometimes these take the form of new problems for the medical man. The advent of the present fashion of bobbing and shingling has caused the virtual disappearance of the hairpin and the appearance, in enormous numbers, of an appliance called the Kirby grip, used as a hair slide. Many girls hold the grip in their mouths whilst their hands are engaged in doing their hair, and every now and then it is accidentally swallowed. In an adult this probably does not matter; the foreign body is generally passed without difficulty. In children it is otherwise. The length and shape of the Kirby grip are such that, though it gets out through the pylorus, it cannot negotiate the fixed curves of the duodenum, and it comes to lie vertically in the second part. Here it will remain for an indefinite time, and no doubt eventually perforation of the bowel would occur in a good many of the cases. I have within the past two months had two such cases under my care, in girls of 2 and 5 years respectively. In both the skiagram showed

the grip lying vertically in the duodenum; after fourteen days its position had not changed. In these circumstances we felt that operative removal was necessary, but here an unexpected difficulty was met with. The duodenum in a child lies deep, and is not easy to approach; the surgeon is very loath to make an incision in it because of the well-known dangers of duodenal leakage. An effort was therefore made to push the foreign body up into the stomach, or on round the third and fourth parts of the duodenum into the jejunum. In both patients this was found to be quite impossible.

In my first case, very reluctantly, I incised the second part of the duodenum, extracted the grip, and closed the incision. There was rather alarming vomiting for about twelve hours, but the child happily made a good recovery. One did not care to run such a risk again in the second case, so I made an opening in the stomach, dilated the pylorus from within with the finger, and fished for the foreign body through the stomach and pylorus with a forceps. This presented no difficulty, and the child did well, without any alarming symptoms. This is undoubtedly the proper way to deal with children suffering from this mishap.—I am, etc.,

Department of Surgery, Bristol
University, Nov. 11th.

A. RENDLE SHORT.

Anaesthetic Explosions from Static Discharge

SIR,—Although attention has been drawn in this country from time to time, as the result of accidents, to the danger of ignition of anaesthetic vapours by such external sources as a light or cautery, it seems to have been generally assumed that the possibility of explosion from static or frictional electricity does not exist here. Such cases, however, have not infrequently been reported from the Continent and from America, and my own experience as given below shows that frictional discharges capable of producing dangerous sparks do occur in theatres in London at present, and that therefore, in the absence of precautions such as the grounding of apparatus and the use of non-insulating rubber, explosions of suitable vapours are to be expected here as they have occurred elsewhere.

On my first visit to a newly built clinic some years ago I was told by a theatre sister that shocks were got from the trolleys. Naturally sceptical, and thinking of ordinary short-circuits, I asked for a demonstration, and was shown that after drawing off the coverlet from a rubber-mattressed trolley a sharp spark, with shock, was obtained on touching the latter. Another example, though less striking, has often been met with in a hospital where, with gas and ether or gas and oxygen, an ordinary two-gallon bag is used with a mask and three-way cock. It has often been noticed—on one occasion before the filled bag was applied to the patient—that particles of fluff, cotton, etc., on it were standing on end and were attracted to the finger, showing that the bag was electrically charged. Further, on stroking the bag with the hand, distinct crackling sparks have been heard, though cautious attempts to ignite ether thereby have so far failed. The first occasion on which this electrically charged bag was noticed having been in the hot, dry weather of last summer, it was thought that this might be an important factor, but it has been met with since on damp, muggy days. The theatre in question has efficient central heating, and the sterilizers are at a distance in an adjoining room, conditions which apply also to the first-mentioned clinic.

It may be assumed, therefore, as stated above, that in modern hospital buildings explosions from "static" may be expected to occur from time to time.

Incidentally, it is of interest to note that Dr. M. Tiegel, in an article describing the use of superheated ether vapour in anaesthesia, states:

"Following an ether explosion in the operating room of a surgical clinic, by which persons taking part were seriously injured, the Minister of the Interior has recently issued an edict giving warning of this danger and laying down safety regulations (*Zentralblatt für Chirurgie*, 1934, No. 40, p. 2317).

—I am, etc.,

London, N.W.9, Nov. 19th.

R. J. CLAUSEN, M.B.

"German Measles"

SIR,—We may agree with Dr. Summerhayes MacRae (*Journal*, November 3rd, p. 835) as to the unsuitability of the term "German measles." Unfortunately, it has a long start and official recognition. The use of the term "rubella" to parents leads to questions which result in the admission that it is only a scientific name for German measles. It is better, at present, to devote one's efforts to explaining that measles and German measles are separate diseases.

It is not easy to settle a satisfactory nomenclature for this disease. In this country "rubella" is generally accepted as the professional term, but its international ring is deceptive. The Germans call it either "röteln" or "rubeola," and the French "rubéole." As you have pointed out, the official *Nomenclature of Diseases* unfortunately gives German measles first with "rubella" and "röteln" as synonyms; "rubeola" is not mentioned. The official *International List of Causes of Death*, 1931, gives "German measles," with subsidiary titles of "röteln" (spelt with the long-abandoned "h") and "rubeola." It gives "rubeola" as a synonym for measles, which must surely be incorrect, and in the *Suggestions to Medical Practitioners* it is stated that "the term is best avoided, as it is used for both measles and German measles."

The term "rubeola" is practically unknown in this country, while "röteln" is too Continental for our use. "Rubella" is clearly the best official title, but it will need many decades to make it familiar to the public.—I am, etc.,

London, W.1, Nov. 13th.

H. LETHEBY TIDY.

Spontaneous Regression of Cancer

SIR,—In the Long Fox Memorial Lecture, delivered in Bristol last November, and published in the *Bristol Medico-Chirurgical Journal* (1933, 1, 228), Mr. C. Joll declared that he had records of 400 cases of spontaneous cures of cancer. This surprising statement was made in criticism of my method of treating inoperable cancer. I wrote immediately to Mr. Joll and asked him to be good enough to publish details of only twenty really authenticated cases of spontaneous regression untreated by any medical, surgical, or radiological method. Such a publication would be of extreme interest to others than myself.

If one relatively so young as is Mr. Joll can have personal knowledge, or details, of such frequent spontaneous cure it leaves me to wonder whether there is a cancer problem, why there is a need for cancer research, and whether cancer hospitals are necessary, for spontaneous cure must be a thing of everyday occurrence. I have given Mr. Joll a year in which to reply to my challenge, but there has been no answer. He has made an incredible statement in a paper which might be regarded as of some scientific value. I now publicly ask him to

give some proof for his remarkable statement: authenticated details of twenty cases from his list of 400.—I am, etc.,

Clifton, Nov. 11th.

A. T. TODD,
Honorary Physician, Bristol Royal
Infirmary.

•• We find, in the *Bristol Medico-Chirurgical Journal*, that the words actually used by Mr. Cecil Joll were: "It is only fair to state, too, that there are records—some highly circumstantial—of nearly 400 cases of complete spontaneous cure of cancer."—Ed., *B.M.J.*

Ingrowing Toe-nail

SIR,—The letter of Mr. W. Kent Hughes, in your issue of November 17th, and Dr. L. Keyes's article,¹ annotated in the *Journal* of August 11th this year, do not draw attention to the fact that a touch of blue-stone, allowed to dry on, daily for about ten days, will cure any ordinary case of early ingrowing toe-nail. The daily coagulation should be left to peel off and should not be cleaned up. Some of the older country practitioners know this method well, and its use saves much needless suffering and risks. Another method is to cut a V down to the quick in the middle of the nail and to keep it pared. This method takes some weeks and often fails.

Considering the suffering caused by the condition of ingrowing toe-nail and the difficulty of feeling sure that all the matrix has been removed at the time of operation, as anyone knows is the case who has done it often, the advantage of the simple blue-stone method from the patient's point of view is obvious.—I am, etc.,

London, W.1, Nov. 19th.

G. H. COLT, F.R.C.S.

Differential Diagnosis of Chronic Rheumatic Disease

SIR,—I am glad of the opportunity afforded by Dr. Copeman's letter in your last issue to correct a misprint in mine of the previous week. For non-articular arthritis read non-articular *rheumatism* (eighth line from end).

Incidentally, I did not state that the sign was new. As to its reliability, we must await the verdict of those members of the profession who may try it out. Dr. Copeman's letter should, at any rate, help to stimulate their interest in what I believe to be an extremely important diagnostic sign.—I am, etc.,

London, W.1, Nov. 19th.

H. WARREN CROWE.

•• It was not a misprint. Dr. Crowe wrote "arthritis" and passed it on the proof.—Ed., *B.M.J.*

Dosage of Vitamin D

SIR,—I read the leading article on dosage of vitamin D in the *Journal* of November 17th (p. 907) with interest. I have not yet seen the actual report by the Toronto workers on this subject, but from your review there would appear to be many aspects of their experiments open to criticism. The children were treated at home, where it is impossible to ensure accurate supervision of such vital factors as exposure to sunlight, adherence to standard diet, etc. Hospitalization is essential to reliable data.

I welcome the final suggestion that "the time is surely ripe for an investigation, on an even wider scale than the present one reported from Toronto, to settle by clinical trial, in terms of vitamin D, what is the minimum protective dose at each age period, and what is the best medium for its administration." Might I refer you to my article in the *Lancet* (June 30th, 1934), in which I described, from the curative point of view, experiments

¹ *Journ. Amer. Med. Assoc.*, May 5th, 1934, p. 1458.

similar to those performed in Toronto and, I would suggest, possessing a more scientific basis? In these I found that one drachm of cod-liver oil given daily over a period of six to seven weeks would heal a moderately severe case of rickets at the age of 3 years, and I would presume a smaller dose would prove effective as a preventive measure for a younger child.—I am, etc.,

Cleethorpes, Nov. 17th.

JAMES R. W. HAY.

Residual Infection of the Jaws

SIR,—Agassiz, the naturalist, wrote: "Every great scientific truth goes through three stages. First, people say it conflicts with the Bible. Second, they say it has been discovered before. Third, they say they have always believed it." I thank Mr. Badcock and Mr. Ainsworth for commenting on my letter calling attention to the Novitzky technique for removing teeth. Their comments may accomplish more than I anticipated my letter would, for they focus attention upon the present methods of removing infected teeth.

If the ordinary method is entirely satisfactory to those who practise it, to those upon whom it is practised, and to those physicians and general surgeons who expect beneficial results to follow the removal of infected teeth of their patients, this pulling method will continue to be used without modification or improvement. There are, however, a not inconsiderable number of dental practitioners, patients, and medical men who are not satisfied. They do not consider this method the epitome and perfection of considerate, careful, complete surgery. Further, in a comparatively recent issue of the *Journal* there appeared a letter or letters complaining of the haemorrhages which physicians are called upon to arrest after the removal of teeth by this method. Medical protective associations are called upon to defend practitioners and settle claims for damages following the removal of teeth by the pulling method. Coroners not infrequently conduct investigations following the employment of the common method. Professor Anderson of St. Andrews spoke as follows, in Dundee, last August:

"I would ask you, gentlemen, as senior members and teachers of the profession, to warn the younger generation to treat these cases of massive extensive extraction as a major operation which should receive full reverence and care in pre- and post-operative treatment."

Mr. Badcock finally declares I have "a good case." It would be difficult for me to disagree with him. But if, as he suggests, I have "marred it," perhaps the following evidence will restore it: X-ray examinations of over 30,000 patients in the Mayo Clinic disclose that from 25 to 45 per cent. have roots left in their jaws after incomplete extraction by the ordinary method; 10 to 25 per cent. had infections still persisting in their jaws after the complete removal of the tooth or teeth. Almost any experienced radiologist could duplicate these percentages were he to tabulate the results of his dental x-ray examinations of patients who have had more than two or three teeth removed. An experienced radiologist in Paris, two or three in London, and my own personal experience in taking x-rays of teeth for twenty-two years confirm these percentages. These examinations, however, disclose only those cases in which nature has been unable to eliminate the infection or the roots after some months or years. There is still another large percentage, I believe, in which nature has eliminated the infection and the undisturbed roots—by extrusion, exfoliation, pus formation, and discharge, which frequently takes weeks, months, years. In the meantime the infection continues, which the extraction of the teeth is expected to eliminate.

I fail to detect any evidence in the two mentioned letters that the Novitzky technique has been employed

consistently on any considerable number of patients and has been discarded because it has failed in any particular to meet the claims made for it. Those who have employed it, however, after having practised the pulling method for years, report to me that they are surprised and gratified when comparing the results of the Novitzky technique with the older method, and note the great reduction in pain, the quickness of healing, the absence of complications, and the satisfaction of their patients.

The absence of reactions and the comparative safety with which Novitzky's technique may be employed on such patients who are seriously ill and in whom infected teeth are believed to be contributing to the condition have been reported by others. Where it is considered dangerous to remove teeth by the older method this method may be used, after proper preparation of the patient, with comparative safety. In regard to convalescence, 95 per cent. return in two, three, four, or five days; they walk in—are not carried in—to have sutures removed, and not a few to have impressions taken for plates to be inserted in a few days' time. This method is practised "in the patient's best interest." But it is also the dental practitioner's best interest to do complete, careful, workmanlike surgery.—I am, etc.,

London, S.W.19, Nov. 3rd.

ALONZO M. NODINE.

Local Treatment of Coryza

SIR,—If you will permit further correspondence on this subject I would like to endorse Dr. Douglas Webster's attitude (*Journal*, November 10th, p. 882), and am glad he mentions the use of short-wave therapy. Admittedly it is not an economic treatment. I have "aborted" some dozen cases which I have come across incidentally, only choosing those in which a cold invariably lasts about ten days. Perhaps more dramatic are cases of tonsillitis—for example, "Wimbledon throat"—tracheitis, and laryngitis, when treated early. Here one treatment usually relieves the symptoms, but should be followed by two further treatments in twenty-four hours to completely clear. When the infection spreads rapidly to the bronchial tubes irradiation with short waves does relieve, but with our present apparatus it is a tedious proceeding to deal with a large field adequately, and so some relief may be given, but reinfection takes place. The treatment is simple in application, with little inconvenience to the patient. I use the six-metre wave-length.—I am, etc.,

London, S.W.1, Nov. 12th.

JOHN KALMANSON.

Motor Backache and Neuralgia

SIR,—Dr. Astley-Weston's letter on this subject in the *British Medical Journal* of November 3rd (p. 834), while endorsing the views expressed in my letter of the previous week, suggests that in the proper construction of a motor seat it is important to eliminate the strain due to "cornering." Others have supported this view. In what was an individual description of experience there was no intention to deny other factors which might contribute towards motor backache. Physical build and health of the driver, construction of the seat and its setting, and suitability of the driver to the particular seat are all of importance. Most people try a pair of boots on before purchasing them, but few take similar care that the seat of a new car is suitably placed and shaped.

"T. W. G." points to the importance of the avoidance of lounging by motor drivers. No doubt this is one of the particular offences of the laid-back bucket-seat—it insists on the driver lounging. In seat construction vibration should be damped and the seat well set, and I believe that, while the back should be nearly vertical, the

floor should be at approximately a right-angle, level, and of sufficient depth. It might be advantageous to round off the angle between floor and back. The development of a large bulge at a higher level in the back, as commonly provided, is a mistake, I think; something flatter is really better. But all these points could easily be determined by experiment at any motor works where their significance was recognized.—I am, etc.,

London, W., Nov. 16th.

G. H. A.

Medical Benevolence

SIR,—As the son of a general practitioner, and as a subscriber to both the English and the Irish Royal Medical Benevolent Fund societies, may I say a few words on the views expressed in the correspondence now appearing in your columns regarding the alleged indifference of medical men as a whole to the distress among their professional brethren?

To begin with, it appears to be generally forgotten that after some forty to fifty years of day and night work the total estate of a doctor, according to the details which appear in the daily papers, averages the small sum of £3,000. This, he naturally thinks, is the bare minimum amount which gives some security to his dependants; but quite 25 per cent. of doctors fail to accumulate even this sum. Moreover, there is a constant drain on the country doctor's resources by way of subscriptions to the charities—religious, social, and political—associations, too, which are all bound up with the people among whom he lives, and who look upon him as their guide, philosopher, and friend. Things do not, therefore, appear so rosy when seen from the inner circle of the average doctor's life, and some measure of justice must be meted out to the much-misunderstood non-subscriber to the medical charities, particularly when they are criticized by wealthy specialists and by those doctors living in large towns and cities with large cash and panel practices, whose relations with their patients are not so intimate as that of the country man.

Until such times as an "all-in" insurance scheme, such as that under consideration by the British Medical Association, is in operation, it occurs to me that the Royal Medical Benevolent Fund authorities should consider the advisability of circularizing that numerous body of lay men and women who get good pay as secretaries, clerks, library assistants, and so forth from those institutions associated with the medical profession. These people depend upon it for their living; they have none of the risks involved in its practice; they all enjoy sheltered lives, save money, and live to a good old age in the enjoyment of a good pension.—I am, etc.,

FAIR PLAY.

London, N.W.3, Nov. 11th.

Whither General Practice?

SIR,—I am interested in Dr. Kenwood's letter in the *Journal* of November 10th, but I venture to think that the problem is not such a simple one as his letter might appear to suggest. He stresses the point that "in many cases patients enter these institutions [the smaller hospitals and nursing homes] solely because of the better nursing arrangements and facilities therein provided"; yet in the smaller hospitals staffed by local practitioners to which he refers the majority of cases are found to be surgical emergencies and road or other accidents, because, with a limited accommodation, the criterion is whether the case is such that treatment in hospital is essential; and, consequently, by reason of their lesser urgency, cases solely requiring better nursing arrangements and facilities are necessarily few.

The solution of the problem of the entry of the patient's own doctor into these hospitals to undertake treatment is by no means simple. Those mainly concerned are the patient, his doctor, the hospital authorities, and the medical staff, and each of these have points of view which must be brought into harmony for the successful working of any scheme. Without attempting to deal with the subject at all exhaustively, there are a few points to which attention should be directed. It must be remembered that, without constant practice in those branches of medicine and surgery which do not enter into the usual routine work of general practice, one is not able to maintain that standard of efficiency which the patient has the right to demand when in hospital—and the patient and hospital will suffer. Again, the satisfactory treatment of a patient in hospital is very dependent on a close understanding between the nursing staff and the doctor in charge of the case. Consequently, it seems that an entirely unrestricted access to treat patients in a hospital would not make for the efficient working of the institution or benefit of the patient. Moreover, from the hospital authorities' point of view, this free access would make it difficult to obtain a medical staff when all the privileges could be obtained without accepting any of the responsibilities.

As a suggestion, there seems much to recommend the policy of making the medical staff open to all practitioners residing and practising in the district, and restricting the treatment of patients to these doctors who accept their share in the medical administration, routine work, and the treatment of patients from other districts or those whose own doctors do not desire to treat them in hospital. This would ensure that those who have the right to treat patients in the hospital were in close touch with hospital work, the nursing staff, and the administration of the hospital.—I am, etc.,

Mitcham, Nov. 12th.

G. M. STOKER.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ANNUAL MEETING OF FELLOWS AND MEMBERS

The annual meeting of Fellows and Members of the Royal College of Surgeons of England was held on November 15th. Sir HOLBURN WARING, President, was in the chair.

The Council's Report

THE PRESIDENT presented the annual report of the Council and called attention to some features of special interest. He said that overseas examinations was a subject which had been very much developed of recent years. In the present year there were to be examinations in Melbourne, for which fifty-eight candidates would present themselves, and in Dunedin, for which there were about twenty-seven candidates. A rather radical change had been made in the Final Examination for the Fellowship—namely, that candidates must have held for not less than six months the post of resident house-surgeon or other responsible post in charge of general surgical patients in the wards of a general hospital recognized by the Council for the purpose. He also stated that for some time dissatisfaction had been expressed with regard to the Primary Fellowship, and the Council had appointed a committee to go through all the complaints that had been made. He believed a number of minor improvements would be made in the examination itself and in the curriculum.

Legislation regarding patent medicines was a thorny subject, and the Council had appointed a special committee to deal with it. The subject had been under discussion at the Ministry of Health and in the profession generally, and, to a less extent, in the licensing bodies. After a very lengthy consideration the Council had come to the conclusion that certain recommendations should be made to the Committee on Scientific Research of the Economic Advisory Council—namely, that the sale of proprietary medicines and appliances should be under the control of the Ministry of Health, and that such control should ensure that the article in question

was not injurious, the description of its therapeutic action not fraudulent, and its sale and methods of advertisement not against the public interest; further, that no medicine or appliance should be advertised as a cure for certain specified diseases and conditions.¹ The British Medical Association and other bodies were taking an active part in connexion with this matter, and he trusted that the result of their efforts would be some satisfactory legislation to remedy the present iniquitous state of affairs, first, as it affected the community, and, secondly, as it affected the medical profession.

The President touched on other details in the report, and mentioned the appointment of Dr. John Beattie of Montreal as conservator of the museum and director of research on the retirement of Sir Arthur Keith. The Buckston Browne Surgical Research Farm had now been completed and was working very satisfactorily. With regard to the diplomas issued by the College, during the year there had been 600 new Members, 81 new Fellows, and 154 new Licentiates in Dental Surgery. A number of other diplomas had been issued, including eight in medical radiology. The Council had the right to elect two Members to the Fellowship every year, and this year had elected Dr. G. A. Buckmaster, Emeritus Professor of Physiology in the University of Bristol, and Mr. G. F. Stebbing, surgical specialist to the London County Council. The President added that he, as representing the College, was to open the new building of the Royal Australasian College of Surgeons at Melbourne next March.

A short discussion followed on the reception of the report. Dr. MORRIS WHITBY suggested that Members of the College who had been practising surgeons for ten years or more should be allowed to sit for the Fellowship in one stage, instead of two stages; he thought that would be of assistance to many Members who had served during the war. The PRESIDENT replied that this was not a feasible proposition, as the Charter of the College laid it down that there must be a Primary Examination and a Final Examination, but he hoped that measures would be taken which would be to the advantage of the persons to whom Dr. Whitby had referred.

Members and the Council

Mr. F. MCG. LOUGHANE then moved the time-honoured resolution:

That this forty-fifth annual meeting of Fellows and Members of the Royal College of Surgeons of England reaffirms that the Members, who constitute 90 per cent. of the College, should have some representation on the Council, a similar resolution having been passed forty-four times and never once lost.

In doing so, he said that the Members numbered about 18,000 and the Fellows only 1,800, and the full financial support of the College rested on the fees that came from the Members. It was very undemocratic that those who paid should not have any vote, and it was only fair that the Members should have a vote for members of the Council and that they themselves should be eligible for election to the Council. The Members had approached the Privy Council on the matter, but without success. In 1930 a poll was taken, and there was an overwhelming vote in favour of direct representation of the Members—6,536 in favour, and only 156 against.

Dr. P. B. SPURGIN seconded the resolution. He asked the Fellows whether, if they had relations who had contributed very largely to their exchequer, and who were suffering from some comparatively small ailment which required only a little surgical interference, they would hesitate to perform the operation in question. He thought it should be performed, as it was necessary to the good health, happiness, and contentment of the "patient." A large number of Members of the College had attained important positions in public life and would not be unworthy representatives of their profession if the Council would admit one or two or even three of them to its table. They would add lustre to the Council and increase its dignity in every respect.

The resolution was supported by Dr. RICHMOND ROCHER and Dr. H. E. WATKINS, who expressed the view that the training of medical students could be greatly improved if there were general practitioners of standing on the Council to assist the Fellows in their deliberations on the regulations for such training.

The resolution was carried by 26 votes to 1, and the meeting ended.

¹ See *British Medical Journal*, November 3rd, 1934, p. 822.

The Thomas Vicary Lecture will be delivered by Professor William Wright at the College on Thursday, December 6th, at 5 p.m. His subject will be "Galen on the Eye."

Mr. Victor Bonney will deliver the Bradshaw Lecture at the College on Thursday, December 13th, at 5 p.m., on the subject of "The Functional Derangement of the Intestine that follows Abdominal Operations."

UNIVERSITY OF CAMBRIDGE

At a congregation held on November 17th the following medical degrees were conferred:

M.D.—R. B. Mayfield, R. W. Butler.

M.B., B.Chir.—P. H. R. Ghey, B. S. Jones, J. C. G. Anderton, R. Q. Parkes.

M.B.—A. M. Barrett.

* By proxy.

Medico-Legal

MEDICAL MAN'S LIBEL ACTION SETTLED

On November 8th a settlement was announced of a libel action brought by Dr. David Nabarro, F.R.C.P., director of the pathological department of the Hospital for Sick Children, Great Ormond Street, against Messrs. Virtue & Co. Ltd., of Thavies Inn, E.C., the publishers of a book entitled *The Milk Trade and Dairy Industry*, and Mr. C. Raison, the editor of the book.

Mr. C. B. Guthrie (for Mr. Cartwright Sharp, K.C.) for Dr. Nabarro said that the case had been settled on agreed terms.

In the month of January, 1930, Dr. Nabarro jointly with one Mr. J. O. Hickman, a barrister-at-law, had written an article called "The Irradiation of Milk," which was published in the *Lancet*. The defendants, Virtue & Co. Ltd., in August, 1933, published a book called *The Milk Trade and Dairy Industry*, and in this book, which was edited by the defendant Raison (who had died since the action was brought), they included a chapter headed "Irradiated Milk," purporting to have been written by the plaintiff and Mr. Hickman. The chapter in fact was a truncated version of the article which had appeared in the *Lancet* more than three and a half years earlier, and the publication of it and the use of Dr. Nabarro's name in connexion therewith were entirely unauthorized.

Dr. Nabarro considered that the user of his name in a trade book on a technical subject might do him considerable harm in his profession, and the inclusion of his name as a contributor in the book might create the impression that he was the type of person who would disobey the rules of the General Medical Council with regard to advertising in order to make money out of journalism or out of the milk trade. Moreover, the investigation of the subject of irradiated milk was one which had made considerable progress since the time the article was originally written for the *Lancet* in January, 1930, so that at the time of publication of the book the contents of the chapter were stale and out of date. Dr. Nabarro's position in the profession left him no alternative but to bring an action to restrain the further publication of the book and for libel. Messrs. Virtue & Co. Ltd., immediately the matter was brought to their notice, consented to an injunction and deleted the offending chapter from their book. They further had agreed through their counsel to apologize to Dr. Nabarro for the inconvenience they had caused him by their action, and to pay him an agreed sum for damages and costs.

Mr. Herbert Malone, for the defendants, said that his clients very much regretted that Dr. Nabarro had been put to any inconvenience through any action of theirs, but they were under the impression that the editor, the late Mr. Raison, had obtained all necessary consents to the publication of articles in the book. They appreciated that the matter might have led persons to believe that Dr. Nabarro had been guilty of unprofessional conduct, and they realized the harm that might have been done to him thereby in his professional status. They had done what they could to remedy the damage immediately the matter was brought to their notice, and they desired through him to tender to Dr. Nabarro in open court their unqualified apology for their error.

Mr. Justice Swift, in allowing the record to be withdrawn, said that he was pleased the parties had come to an amicable settlement, and that Dr. Nabarro left the court without any aspersions on his professional behaviour.

Obituary

VINCENT MIDDLETON COATES, M.C., M.D.,
M.R.C.P.

The tragic death of Dr. Vincent Coates has come as a great shock to his many friends both in Bath and throughout the country. His circle of friends must have been a peculiarly large one, for both as a Rugby international in his earlier years and as a physician of repute in later life he made many contacts, and once a contact was made a friendship remained. Educated at Haileybury and Cambridge, he made his mark as an athlete from the first, captaining the school in 1906-7 and gaining his Blue in 1907 at the age of 18. Owing to trouble with his knee he was unable to take part in the Varsity match in his later years of residence, but subsequently played for Bath, Somerset, and England, gaining his international cap in 1913 and playing for his county on five occasions.

Dr. Coates qualified in 1915 and immediately joined the R.A.M.C., and, after being awarded the Military Cross in 1916 in France, proceeded to Salonica, where he was in charge of a bacteriological unit, and served there till the end of the war. After some months of post-graduate work, during which he took his M.D. Cambridge, he settled in Bath in 1919, in the house of his grandfather, the late Dr. C. M. Coates, who had attained distinction as a physician in the city in the pre-war period. Later

Coates was admitted a Member of the Royal College of Physicians, and became a member of the committee set up by the College for the study of arthritis. From the first he identified himself with the study and treatment of rheumatic diseases, and contributed several articles in various journals dealing with these and cognate matters, and published with L. Delicati a book entitled *Rheumatoid Arthritis and its Treatment*. He was appointed a physician to the Royal Mineral Water Hospital, Bath, in October, 1921, and had been senior physician to that institution since May, 1932. He took a leading part in both national and international societies dealing with rheumatic disease, spa treatment, and hydrology, and had come to be recognized not only as the representative of Bath in these activities, but as one of the chief representatives of Great Britain when these subjects came up for discussion. Coates was, however, not only a specialist in this one branch of medicine, but was an able general physician. Until the hospital was disbanded in 1925, he was specialist in tropical diseases at the Ministry of Pensions Hospital, and served in the same capacity to the medical boards of the South-Western areas. In May, 1921, he was appointed assistant physician to the Royal United Hospital, Bath, and for a short time was on the staff of the Hospital for Women and Children, Bristol. In April, 1934, he succeeded as full physician to the Royal United Hospital, and was already promoting the interests of this hospital with his usual stimulating suggestions for the improvement of its services. He was consulting physician to the Trowbridge and Froshford Hospitals, and cardiologist specialist for Wiltshire. At the time of his death he was president of the Bath Clinical Society and a Fellow of the Royal Society of Medicine and of the Medical Society of London.

At the Annual Meeting of the British Medical Association held in Bath in 1925 Coates was secretary of the Section of Diseases of Children, and had served on various occasions on the executive committee of the local Division. He had been chairman of the Spa Subcommittee of the Division, and was one of their representatives on the Spa Committee of the city council. He was always appreciative of the desirability of the closest co-operation between the Association's central activities and the local profession in hospital and other matters, and was a keen supporter and upholder of its various policies.

With all these public activities he had built up a large consulting practice chiefly devoted to the rheumatic group of diseases. His kindness and ability will be sadly missed by a host of patients, both rich and poor alike, in all parts of the country, for Coates never spared himself when once he had put his hand to whatever roused his enthusiasm, and his energy was extraordinary. With all this hard work and widespread activity he had time to go out of his way to perform those thoughtful and kindly actions which are the gems of human intercourse in all spheres of life. In all respects he upheld the best traditions of the medical profession, and had regard not only to the physical and mental aspects of his work, but also to the spiritual demands and requirements of his patients. Such an accident befalling such a man at the early age of 45 is a disaster of the first magnitude, and the sympathy of all will go out to his many friends, to his relatives, but especially to his widow.

[The photograph reproduced is by William Clark, Bristol.]

R. H. DICKSON, F.R.C.S.I.

Ophthalmic Surgeon, North Staffordshire Royal Infirmary

By the death of Robert Harper Dickson, on November 9th, at his home, Grindley House, Newcastle-under-Lyme, after a long and tiring illness, North Staffordshire has lost a well-known and much respected citizen, who has left behind him a long record of honourable professional work.

The son of a well-known Irish doctor, Mr. Dickson qualified in Dublin in 1887, and was then house-surgeon for two years at St. Mark's Ophthalmic Hospital. He came into close contact with the teachers of surgery and medicine of a former generation, for whom he had a great admiration. Mr. Dickson came to England and started in general practice in Newcastle, Staffs, eventually taking sole charge of a widespread district. For many years he was a familiar figure driving round this district in his dogcart. His duties entailed attendance at the local workhouse. Here he left behind a record of work well done and of many kind acts to the inmates. An inveterate pipe smoker, he often emptied his large tobacco pouch for the benefit of the patients. His interest lay chiefly towards diseases of the eye, and he eventually gave up general practice and devoted himself entirely to his speciality. He became assistant ophthalmic surgeon to the North Staffs Royal Infirmary, and subsequently proceeded to the senior post. He was also appointed eye surgeon to the Stoke Guardians' Institution and the Orthopaedic Hospital, and was medical referee for eye diseases under the Home Office, in which capacity he had to deal with many cases of miners' nystagmus.

He joined the B.M.A. in April, 1892, and always found time to devote to the affairs of the Association. He had been in turn president of the local Branch and also chairman of the Division. Mr. Dickson was a member of a small committee which successfully revived the North Staffordshire Medical Society, and it is now a flourishing and useful institution in the local medical life. He was one of the first presidents, and gave a most useful address on his work as an eye surgeon. During his forty years

in this district his work as a general practitioner and as a specialist brought him into contact with a large number of patients. He never lost interest in anyone he had seen professionally, and he had the faculty of keeping them as friends. For this reason his death is a personal loss and sorrow to a large number of the inhabitants.

Mr. Dickson had a wide sphere of interest outside his professional work, and was a keen and popular member of the Newcastle Rotary Club, of which he had been president, and of the North Staffordshire Field Club. He is survived by his wife and family, of whom there are three sons and two daughters: much sympathy is felt for them in their bereavement. Two of the sons are students of medicine in London.

The death took place, on November 16th, of Dr. JOHN SMITH, who had practised at Kirkcaldy for some forty years. Born in 1855 and educated at Ayr Academy and Edinburgh University, he graduated M.A. at Edinburgh in 1878 and M.B., C.M. in 1881, taking the English conjoint qualification also in 1885, and proceeding to the M.D. in 1886. After graduation he acted as resident surgeon in the wards of Edinburgh Royal Infirmary under the late Professor Annandale, and later in the Edinburgh and Glasgow Maternity Hospitals, and as clinical assistant in the Royal Ophthalmic Hospital at Moorfields. Entering practice at Kirkcaldy in 1894, he became one of the best-known practitioners in Fife, and had been a medical referee under the Workmen's Compensation Act since 1906. He was a Fellow of the Obstetrical Society of Edinburgh and of the Ophthalmological Society of the United Kingdom. Although he was locally well known as a practitioner of medicine, Dr. Smith was more widely celebrated in the world of sport, and was an international Rugby player of great fame. He had played Rugby football since his school days, and from 1877 he represented Scotland six times against England and four times against Wales. He was also the founder of Association football at the University of Edinburgh, and after 1884 he took up this form of the game and played in many important matches. In the year 1894 he went to Australia as manager of the Shaw-Shrewsbury British team, and again played Rugby football in that country. On taking up practice in Kirkcaldy, however, he gave up football altogether and took to bowls, golf, and curling, at which he achieved great skill. In bowls he appeared in several international contests, and was vice-president of the Scottish Bowling Association in 1924. Dr. Smith had been a member of the British Medical Association for fifty years.

By a sad coincidence *A Soldier in Science*¹ reached us almost at the same moment as the news of the author's death, at his home in Porto Rico, at the age of 61. Colonel BAILEY KELLY ASHFORD, professor of tropical medicine and mycology at Columbia University, was the son of a professor of surgery and dean of the medical school at Georgetown, who, dying when the boy was but 10, left him with the passion to be a doctor of medicine. How he forged ahead with his programme of active life and research to reach an eminence far beyond his most ambitious dreams is told vivaciously in his book. For it was research that called him as soon as he realized its possibilities. On graduating, therefore, he joined the Army, hoping thus to secure a settled income and adequate spare time, but shortly afterwards war with Spain broke out. He had a brief spell of active service, and then settled down in charge of a hospital near Porto Rico, thus entering, unsuspectingly, upon the drama of his life. A furious hurricane was followed by epidemic anaemia, and the way began to Colonel Ashford's discovery of hookworm infection. The description of the stages in convincing others of the truth of this explanation makes arresting reading, as does also his account of the subsequent founding of the

¹ *A Soldier in Science*. The Autobiography of Bailey K. Ashford. London: George Routledge and Sons, Ltd. 1934. (12s. 6d. net.)

Porto Rico Commission in 1904, which began the first campaign against the disease in the Western hemisphere, and reduced the death rate from this cause by 30 per cent. From this Colonel Ashford turned to uncinariasis, and then, in 1913, to tropical sprue. The late war brought him to France, where he was actively engaged in 1917 and 1918, receiving battle clasps for the Aisne-Marne and Argonne-Meuse and the D.S.M., and being created an honorary C.M.G. The war interfered with his important work in connexion with the Rockefeller Medical Commission in Brazil, and the establishment in that country of a centre for the study of tropical diseases, as the result of what he aptly terms "a reconnaissance," but the work was completed, nevertheless. On his return from Europe Colonel Ashford was called upon to edit the *American Medical History of the War*, when, as he writes, he was all the time impatient to complete his work on sprue and to convert the Institute of Tropical Medicine in Porto Rico into something permanent and worth while. So he insisted on returning, but the "no truce in the Tropics" sent him first to investigate an outbreak of fever in Cuba. He then achieved his ideals, and was hopefully looking forward to fresh exploits when death overtook him. His autobiography, simply narrated without hyperbole, reads like a modern saga—which, in fact, it is. It tells the tale of the still-continuing yet oldest war of all, man's struggle against nature, carried on with the undying hopefulness and determination which enabled humanity in past eras to overcome many physical foes. This story of the life of a pioneer in restoring many thousand sick and apparently dying to full physical efficiency, of an insatiate explorer of the mysteries of disease, and of a great lover of mankind was eminently worth telling, and is excellently told.

We regret to announce the death, at Mundesley Sanatorium, Norfolk, on November 8th, and after an illness of only a few months, of R. H. MORLEY, M.D., M.R.C.P., aged 30. Dr. Morley was educated at Kingswood School, Bath, and Leeds University, graduating M.B., B.S.Lond. in 1928. He held clinical and pathological appointments at the General Infirmary, Leeds, and then went to London, where he was house-physician at the Brompton Hospital and later house-surgeon at the East London Hospital for Children. After this he went into general practice in Norwich, hoping to get appointed ultimately to the staff of the Jenny Lind Hospital for Children, at which he was clinical assistant at the time of his death. Morley was one of the outstanding students of recent years at Leeds. He was president of the Leeds Students' Union and vice-president of the National Union of Students of Great Britain; he was also a good athlete, representing the university at Rugby football, swimming, and tennis. Though very able, he did not strive after academic honours, but was widely read and possessed a finely critical and original mind. He was keenly interested in art and literature, and had recently written more than one play. He was, moreover, a delightful and stimulating companion, the one above all others one would choose for a holiday. His untimely and unexpected death comes as a great tragedy to his friends, who had foreseen a notable future before him and will deeply feel his loss.

The sudden death occurred, on October 29th, at his home, Hamilton Road, Bangor, Co. Down, of Dr. JAMES C. NICHOLSON. Bangor mourns his death, for he was a most popular practitioner, and the loss is felt all the more because he apparently had many years of useful work before him. Dr. Nicholson had lived for a time in America, but returned to this country to study medicine both at Belfast and at Edinburgh, obtaining the L.R.C.P. and S. diplomas in 1901 and the F.R.C.S.Ed. two years later. From the time he qualified until 1916 he was attached to the John G. Paton Mission, and had charge of the hospital in Tanna in the New Hebrides. He answered the call for doctors during the war, joining the Australian Army Medical Corps, and saw service in France. On

demobilization in 1919, he settled in Bangor, and built for himself a most successful practice. By colleagues and patients alike he was always admired both for skill in his professional work and for uprightness of character: his passing leaves a gap which will take a long time to fill. He was an enthusiastic believer in outdoor sports, and a valued supporter of both Rugby and Association football, being a vice-president of Bangor Rugby Club. He was a member of the British Medical Association and a Fellow of the Ulster Medical Society. His only son, Dr. John C. Nicholson, assisted his father for a time in his large practice. Dr. James Nicholson leaves a widow and four daughters as well as his son.

Dr. A. A. STEWART, who died on November 10th at Northampton, graduated at the Royal University of Ireland in 1893. He entered into general practice at Northampton about forty years ago, and continued his work with marked success practically up to the time of his death. His whole heart was in medicine—so much so that he allowed himself a holiday only with great reluctance, and never had time for recreation. He was greatly esteemed by his patients and a large circle of friends, as was evidenced by the very big congregation at the church service. An old and enthusiastic member of the British Medical Association, he seldom missed the local Branch meetings. He had been an active member of the Local Panel Committee from its inception, and for a number of years up to the time of his death had acted as its treasurer. In 1900 he married Ada, the daughter of James Whyte Stenhouse of Manchester, who, with a son and daughter (both in the medical profession), survives

The following well-known foreign medical men have recently died: Dr. ANGEL GALLARDO, rector of the University of Buenos Aires and member of the Academy of Medicine of Buenos Aires, aged 67; Dr. THEODORE H. WEISENBURG, professor of neurology at the University of Pennsylvania Graduate School of Medicine since 1907, and editor-in-chief of the *Archives of Neurology and Psychiatry* since its foundation in 1919, aged 58; Geh. Med.-Rat Professor Dr. WILHELM VON STARCK, for nine years professor of children's diseases and director of the Children's Hospital at Kiel, aged 76; Dr. ALBERT FERNAU, professor of radiology at Vienna, aged 56; Dr. ALFONSO POGGI, emeritus professor of surgical pathology at Bologna; Dr. G. SALUS, emeritus professor of hygiene at Prague, aged 72; and Dr. W. H. JOHNSON, professor of orthopaedics at Charlestown, South Carolina.

The Services

The King has conferred the Efficiency Decoration of the Territorial Army on Colonel H. F. Humphreys, O.B.E., M.C., K.H.P., A.D.M.S., 48th (South Midland) Division; Lieut.-Colonel R. A. Broderick, D.S.O., M.C., R.A.M.C.T.A.; and Major A. C. Haddow, R.A.M.C.T.A.

NO. 29 GENERAL HOSPITAL

The sixteenth annual reunion dinner of the 29th General Hospital will take place at the Princes Galleries on December 15th, when Lieut.-Colonel S. H. Withers, C.M.G., will preside. Officers are asked to communicate with Captain Percy Groves, Heronfield, Meadowcourt Road, Leicester.

DEATHS IN THE SERVICES

Lieut.-Colonel Ernest Brodribb, R.A.M.C. (ret.), died at Hove on November 10th, aged 61. He was born at Warminster on December 13th, 1872, took the M.R.C.S. and L.R.C.P.Lond. in 1896, and entered the R.A.M.C. as surgeon-lieutenant on July 28th, 1897. He became lieutenant-colonel on March 1st, 1915, was placed on half pay on account of ill-health on January 10th, 1917, and retired on January 19th, 1921.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

A new session of Parliament was opened on November 20th by a speech from the Throne, which promised legislation for the future government of India, for the assistance of distressed areas, for shipping, on electricity supply, and for imperial air communications. The paragraphs referring to housing announced that so great a measure of progress had been attained that the Government was able to contemplate the next step in the process of improving the housing conditions of the people. A Bill would accordingly be submitted for preventing overcrowding and making provision for the rehousing of those found to be living in overcrowded conditions. There would also be a similar Bill applying to Scotland. Measures would be introduced, if time permitted, for the control of building development along the main thoroughfares, for providing better housing of the metropolitan police, and other subjects.

Debate on this programme followed in both Houses. In the Commons the Government proposed that the whole time of the House should be taken for Government business. This does not forbid introduction of Bills by private members, but precludes their passage.

Before Parliament was prorogued, on November 16th, the Royal Assent was given to the Betting and Lotteries Act and the Poor Law Act.

National Health Insurance

Sir HILTON YOUNG told Mr. Tinker, on November 14th, that the number of persons in Great Britain who, on December 31st, 1933, were insured under the National Health Insurance Act was approximately 18,481,000. The age distribution of the persons so insured was last ascertained as at December 31st, 1931, and the number of insured men aged between 55 and 60 was then about 799,000.

The Minister told Mr. Buchanan on that day that he had decided to grant the same extension of the period of grace for the redemption of arrears by insured persons as was given last year, and publicity had already been given to this decision in a circular to all approved societies and by notices in the public press.

In an answer to Sir Arnold Wilson, on November 16th, Sir HILTON YOUNG said that out of about 12,000,000 insured men and 6,000,000 insured women, 9,000,000 men and 2,000,000 women were members of approved societies giving dental benefit. The great majority of the societies paid half the cost of treatment.

St. Mary's Hospitals, Manchester, Inquiry

Sir Hilton Young announces that the authorities of St. Mary's Hospitals, Manchester, have concurred in the request by the City Council of Manchester for an inquiry into the death of a patient. The circumstances of this case were so special as to justify an exception to the established rule against publication of the report of the inquiry.

The Ministry of Health subsequently announced that the report of the inquiry into the death of Mrs. Taylor would be sent to the Manchester City Council very soon for publication, and would also be sent to St. Mary's Hospitals.

Fitness for Marriage

In the House of Lords, on November 14th, Lord KILMAINE moved that the marriage laws should be so amended as to make it obligatory for both parties to produce medical certificates of fitness when they came before a minister of religion or the civil authority. He said he had talked over the subject with many medical men, and found general agreement that legislation on the lines he suggested was needed. He proposed that the solemnization of any marriage in this country should be made illegal unless both the contracting parties could furnish medical certificates of fitness to marry

and to raise a family. These should be signed by some competent medical authority. The fee for them should be fixed as low as possible, and steps taken to ensure that the answers given were true. He proposed four certificates. "A" would show the parties were perfectly fit to marry and raise a family. "B" would show that for reasons of health delay was advisable, but the parties might present themselves again in three or six months; this would be an important provision in suspected venereal infection. "C" would say the parties could marry without danger to each other, but that it must be a childless marriage. It followed that some kind of birth control must be used for the unfit; he hesitated to say sterilization. Lastly, certificate "D" would prohibit marriage altogether in a case where there would be danger to the parties themselves. Legislation on the lines suggested would also diminish the number of lives spoilt by close in-breeding, which, in isolated communities, often resulted in mentally deficient children. He did not propose that couples should undergo medical examination; that would only be necessary where there was venereal disease. In all other cases it would simply be necessary to answer questions relating to general health and family history.

The Bishop of Norwich feared that, failing to receive any of the certificates suggested, many would form alliances from which children might result. He could not imagine that the certificates could be separated from careful medical examination. Many mental disorders were intermittent in their effects, and he foresaw difficulty in disqualifying for marriage, because their fathers or grandfathers had shown some mental disaffection, people who apparently were perfectly sane. Yet these people, adequate in themselves, might be the ones who could not be trusted to rear families. The Archbishop of Canterbury asked who was to certify; was it to be some State official? How was the private practitioner to take the responsibility except perhaps for the clear-cut certificate "A" or "D"? How was he to take on himself the responsibility of saying, "You must delay," or "I think you must be prepared to render yourself childless." What was the minister of religion to say when certificate "B" or "C" was brought? "Have you delayed long enough?" or "Are you quite sure you have made it impossible for you and your proposed wife to have children?" The recent report on sterilization and kindred subjects merited careful consideration, but he hoped the House would not pass Lord Kilmaine's motion as it stood.

Lord GAGE, replying for the Government, said the Ministry of Health regarded the subject as important. There was strong evidence for limiting the right to marriage of the mentally defective. The evidence of the recent report on the sterilization of mental defectives showed the suffering and misery which so often afflicted their children. The Committee on Sterilization had not dealt with the legal marriage of mental defectives, but the Board of Control on several occasions strongly recommended its prohibition. At present mental defectives in institutions were incapable of marriage. Under guardianship the consent of the guardian was required, but if a defective evaded the guardian's consent the marriage was valid. The Departmental Committee on Sterilization did recommend a form of voluntary sterilization, but was also of opinion that any hint of institutions being associated with compulsory sterilization would keep people from going for treatment and induce concealment from medical attendants. The loss of rights of marriage was less severe than sterilization, but any action by the State of that kind might drive underground facts which, in the interest of the State and of the individual, ought to be brought to the notice of the medical profession. To some people of nervous temperament dread of a medical examination would deter from a legal marriage, and it might tend to increase the illegitimate births. He agreed with the Archbishop that a medical certificate based on anything but a medical examination would not be a medical certificate at all. The Minister of Health and his advisers felt there was enough evidence, over a large number of years, to justify their testing public opinion, as they were doing in regard to the reports of the Board of Control and the Committee on Sterilization. The report of that Committee was being considered by institutions and bodies interested. Beyond that the Government could not go for the time being. To go on the lines suggested by Lord Kilmaine without large evidence of public and medical support would be disastrous.

Lord Kilmaine then withdrew his motion. He remarked that any doctor examining people should put down consumption, insanity, venereal disease, or close blood relationship as bars to the production of children.

Compensation for Compulsory Vaccination

Replying to Mr. Groves, on November 15th, Sir HILTON YOUNG stated that his attention had been called to the death of a nurse at Birmingham from vaccination, the operation being imposed by a Sheffield institution as a condition of employment. He referred to the remarks on this subject which were contained in the annual report of the Chief Medical Officer of his Department for 1933. Sir JOHN GILMOUR told Mr. Groves, on the same day, that he could not recommend legislation to extend the Workmen's Compensation Act, 1925, to death or injury due to vaccination where the circumstances were not such as to bring the case within the terms of Section 1 of the Act. This restricts compensation to cases of personal injury by accident arising out of, and in the course of, employment. Mr. Groves suggested that the Act should be amended to put on employers the responsibility for the injurious or fatal result of vaccination performed as a condition of employment.

Medical Inspection and Free Milk.—Mr. RAMSBOTHAM told Miss Rathbone, on November 15th, that the Minister of Education was not prepared to withdraw the restriction placed by Circular 1437 upon the freedom of local authorities to give milk or meals free to children on account of their parents' poverty without first requiring a medical inspection. Under any system other than that of medical selection there was a danger of overlooking children who required attention. He attached the highest importance to a close study of defective nutrition and its treatment, and regarded it as in every way advantageous that this part of the work of the school medical service should be linked with the arrangements for provision of meals and milk. Replying further to Miss Rathbone, Mr. Ramsbotham regretted that in the returns supplied to the Board of Education the salaries of school medical officers were not apportioned between the various forms of medical inspection and their other duties. Therefore it was not possible to state the average cost of every special medical inspection and also of every routine inspection of a school child. Asked whether a cost for inspection of 7s. per child was not a large expenditure for the purpose of determining whether a child should receive 2½d. worth of milk, Mr. Ramsbotham said he hoped this would not be grudged in view of the importance of the subject.

Milk-in-Schools Scheme in Scotland.—Mr. SKELTON told Mr. Anstruther-Gray, on November 15th, that the Glasgow education authority had not yet in operation a scheme for the provision of milk under the new milk-in-schools scheme, but a draft scheme had been prepared. When this was in operation about 142,000 children would be included; at present 5,900 children in Glasgow were having milk in schools. Sir GODFREY COLLINS told Mr. Boothby, on November 15th, that the North of Scotland Milk Marketing Board proposed to make arrangements for the supply of milk for schools within the area of its administration. In Aberdeen and district the matter was under consideration by the Milk Marketing Board concerned.

Deaths from Asbestosis.—Replying to Mr. Thorne, on November 15th, Sir JOHN GILMOUR stated that about sixty deaths from asbestosis had been brought to the notice of the Home Office. After investigation all were attributed to exposure incurred previous to the Asbestos Industry Regulations of 1931. The disease usually took years to develop, and the period between commencement and death varied widely. Special inquiry in 1932 as to the risks in warehouse and certain other processes revealed no need for any extension of the regulations. Their effectiveness would continue to be closely watched.

Maternity and Child Welfare Services.—Replying to Miss Cazalet, on November 15th, Sir HILTON YOUNG stated that where there had been a reduction of the amount spent on the maternity and child welfare services the first step was to ascertain the reasons for, and the effect of, the reduction.

If there was reason to fear less efficient services, he directed a local investigation and made the necessary representations to the authority concerned. The expenditure of the grant of £5,000,000, which was included in the general Exchequer contribution for each year in the first fixed grant period under the Local Government Act, 1929, was within the discretion of the local authorities. A condition was that they should maintain a reasonable standard of efficiency and progress in the discharge of their public health functions. The policy of the Government was to secure a development of the maternity and child welfare services, and steps had recently again been taken for the purpose.

Welfare of the Blind: Advisory Committee.—Replying to Mr. T. Smith, on November 15th, Sir HILTON YOUNG said that on the Central Advisory Committee for the Welfare of the Blind, in addition to the representative of the National League for the Blind, there was another member closely connected with the League. He could not at present undertake to add to the size of the committee.

Outbreaks of Foot-and-Mouth Disease.—Sir GEORGE BOWYER stated that no general cause had been discovered for the outbreaks of foot-and-mouth disease in six areas of England during November. In no area had the initial cause been traced, but there was no reason to suspect that the outbreaks were caused maliciously.

Medical News

The Sheffield medical dinner will be held at the Royal Victoria Hotel on Thursday, December 6th, at 7.45 p.m., when Lord Dawson will be the chief guest. Applications for tickets (13s. 6d.) should be made to the honorary secretary, Dr. T. E. Gumpert, 331, Fulwood Road, Sheffield, W.

The annual old students' reunion dinner of the London (Royal Free Hospital) School of Medicine for Women will be held on the evening of Thursday, December 6th, at the Savoy Hotel.

The annual dinner of the London Jewish Hospital Medical Society will take place on December 9th at the Trocadero Restaurant, when Sir Humphry Rolleston will be the guest of honour.

A meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health will be held at 1, Upper Montague Street, W.C., on Friday, November 30th, at 4 p.m., when Dr. J. M. Greenwood will open a discussion on "Puerperal Fever." At the same place and on the same day the Maternity and Child Welfare Group will meet at 8.30 p.m., when a discussion on "Heredity and Mental Deficiency" will be opened by Dr. J. F. Roberts.

A meeting of the medical section of the British Psychological Society will be held at the Institute of Psycho-Analysis, 36, Gloucester Place, London, W.1, on Wednesday, November 28th, at 8.30 p.m., when a paper on "Femininity and Passivity" will be read by Dr. Sylvia Payne.

The Fellowship of Medicine (1, Wimpole Street, W.) announces that lecture-demonstrations will be given at 11, Chandos Street, W., on November 27th and December 4th, at 2.30 p.m., and on November 28th and December 5th, at 8.30 p.m., lectures on diet and dietetics. On December 8th, at 3 p.m., Dr. B. T. Parsons-Smith will give a demonstration of heart cases, especially suitable for general practitioners, at the National Temperance Hospital, Hampstead Road, N.W. The following courses of instruction will take place during the last six weeks of the year: infants' diseases at the Infants Hospital, Vincent Square, S.W., from November 26th to December 8th (afternoons only); dermatology at the Blackfriars Skin Hospital, from November 26th to December 8th (afternoons only); special M.R.C.P. course in chest diseases at the Brompton Hospital, Wednesday and Fridays, at 5 p.m., from December 12th to January 11th (excluding Christmas week). Courses, lectures, etc., arranged by the Fellowship are open only to members.

The offices of the Examining Board in England by the Royal College of Physicians of London and the Royal College of Surgeons of England, at the Examination Hall, Queen Square, W.C.1, will be closed on Thursday next, November 29th, on the occasion of the Royal Wedding.

The governing body of St. Mary's Hospital Medical School has decided that after October 1st, 1935, admission to the school will be restricted to students reading for university degrees. In practice this means the Universities of London, Oxford, and Cambridge. In making this announcement the dean, Dr. C. M. Wilson, states that for some years St. Mary's has given preference to students taking university degrees in the selection of its annual entry. It is now prepared to take the further step of committing the school to this policy.

The annual congress of the British Institute of Radiology will be held at Central Hall, Westminster, S.W., on December 5th, 6th, and 7th. In association with the congress an exhibition of x-ray apparatus will be held in the same building, under the auspices of the British x-ray industry.

The Ministry of Health has issued a Circular (No. 1417) relating to the contents and arrangement of the annual reports of medical officers of health for 1934. The reports this year are of the "ordinary" and not of the "survey" type, the information being limited in the main to recording alterations, improvements, or developments which have taken place during 1934, together with statements of any noteworthy conditions prejudicial to the health of the area and of any special action taken to arouse public interest in the prevention of ill-health. When the boundaries of a district have been materially changed during the twelve months under review, the medical officer of health should comment on any new problems of public health administration created thereby. It is also necessary for the medical officer of health of every district council to report specifically on the administration of the Factory Acts in workshops and workplaces.

The remains of Laennec, which had previously been exhumed in 1846 on the death of his wife, were again exhumed on September 23rd and placed in a leaden coffin in a vault of the church at Ploaré, Brittany, where he died in 1826.

Dr. William Moodie, director of the London Child Guidance Clinic, has been appointed medical consultant to the National Institute's school for mentally retarded blind children at Court Grange, Abbotsekerswell.

The following medical men were elected mayors on November 9th: Dr. W. E. Jones (Leamington), Dr. J. V. Shaw (Hereford), and Dr. H. F. Curl (Wokingham).

Dr. I. A. Jackson (Lincoln's Inn) and Dr. J. C. Pickup (Middle Temple) were called to the Bar on November 19th.

Professor Fernand Bezançon has been nominated general secretary of the International Union against Tuberculosis, in the place of the late Professor Léon Bernard.

Dr. Leon Cardenal, professor of surgery at Madrid and president of the last International Congress on Cancer, has been nominated rector of Madrid University.

Dr. Marion, professor of urology in the Paris Faculty of Medicine, has been elected member of the Académie de Médecine in the Section of Surgery.

A Dutch association for cardiology has recently been founded, with Professor K. Wenckebach of Vienna as president of honour and Professor W. Kuennen of Leyden as president.

The well-known psychologist Dr. C. G. Jung of Zurich has presented 200,000 Swiss francs to the Higher Technical School of Zurich to form a fund for the advancement of psycho-analysis and allied studies.

The Belgian Society of Gynaecology and Obstetrics offers a prize of 10,000 Belgian francs, to be awarded every four years, for the best gynaecological or obstetrical work. Further information can be obtained from the secretary, Dr. M. Cheval, 16, Rue Alphonse Mottat, Brussels.

From March 18th to July 14th 3,107 cases of typhus were notified in Chili, exclusive of 101 doubtful cases.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:
EDITOR OF THE BRITISH MEDICAL JOURNAL, Ailology Westcott, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Ailology Westcott, London.

MEDICAL SECRETARY, Malvern Westcott, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegram: Bactillus, Dublin); telephone: 62550 Dublin, and of the Scottish Office, 7, Drumshigh Gardens, Edinburgh (telegram: Associate, Edinburgh; telephone: 24961 Edinburgh).

QUERIES AND ANSWERS

Priapism after Circumcision

"D. R." writes: Could any of your readers give me any help in the following case? A little boy, aged nearly 5 years, was circumcised when about 3 months old against his father's wish, but by order of the doctor, and the mother wished him to be done. The child was kept by a nurse, but the mother and father noticed, when they kept the child some nights, that immediately on awakening there was an erection. This was when the child was about 2, and this has been noticed since, and the same also when the boy's bladder is full or when he wishes to have a motion. It has caused a lot of unpleasantness, as the father blames the operation for circumcision. It should be stated that the child's father suffered from erections which had nothing to do with sexual excitement, but he was found to have glycosuria, due to renal deficiency, probably congenital. The boy is a normal healthy boy in every way, very intelligent, but the mother is very anxious in case it should lead to masturbation or any other sequel.

Hexyl-resorcin during Lactation

Dr. S. P. WILSON (Wakefield) writes: About two years ago I tried caprolol in a case of cystitis due to *B. coli*. The immediate result was good, but recently the same patient has had a recurrence of symptoms. She is breast-feeding her six-months-old baby. Is the administration of caprolol now likely to affect the milk, either in taste or quality? British Drug Houses Ltd. inform me that as far as they know caprolol is not contraindicated, but the patient is still unwilling to try it at present. I should be glad to hear of experiences bearing on the question.

Income Tax

Replacement of Car

"H. S. F." bought a car in 1925 for £660, but has never claimed the depreciation allowance. In September, 1934, he sold the car for £45 and bought another car for £335. What can he claim?

* A claim for the cost of replacing a car has to be treated as one to deduct a professional expense; that expense was incurred in 1934, and the claim would therefore affect the assessment for 1935-6 only. The amount is the out-of-pocket cost—that is, £335 - £45 = £290. It will be seen that on this basis "H. S. F." loses the allowance for half the original cost of the old car, and it would have paid him much better to claim yearly "depreciation," plus the obsolescence allowance, on replacement being made. He can, however, put in a six years' claim now under Section 24 (1) of the Finance Act, 1923; this

is probably his best course, but possibly it might be advisable to have the assistance of an accountant with that claim.

Interest Paid out of Profits

"R. C." puts the following query. A lends B £1,600 for the purchase of a practice on which B pays £50 per annum interest, and that sum is included in the assessed profits of the practice. Does A also pay tax on the £50?

* B pays tax on the £50 (at full standard rate) as part of the profits of the practice. When he makes payments to A he is entitled to deduct tax, so that a quarterly payment would be £12 10s. less £2 16s. 3d. (tax at 4s. 6d. in the £)—that is, £9 13s. 9d. net. Thus ultimately the tax is borne by A, who, of course, is not assessable for that item of income. If B omits to deduct tax, A is still not assessable.

M.O.H.—Use of Residence

"W. S. H." is M.O.H. under a local authority. He is provided with office accommodation at the council offices and with a telephone at his private residence. Occasionally visitors call at the residence outside office hours. Do these facts justify any claim to deduct a part of the rent, etc., of the residence?

* We fear not. To be deductible from the emoluments of employment expenses must be incurred wholly, exclusively, and necessarily in carrying out the duties of the appointment, and "W. S. H." would probably be unable to convince the authorities that his residential expenses are increased by the installation of the telephone or the occasional calls of visitors on business.

LETTERS, NOTES, ETC.

Metal Cider Taps and Lead Poisoning

Dr. H. H. MOYLE (Stalbridge, Dorset) writes: In a case of lead poisoning in a patient of mine, a mason with nothing whatever to do with lead, I was at a loss as to the cause, for the usual channels were negative. The solution is as follows. The man, of very temperate habits and the only one in the house to take anything at all, used to have a glass of cider at night, sometimes missing a night or so. On examining the tap which he brought up for my inspection I found it to be one of the usual combination wood-and-metal type, and the metal was lead, the key and four small brads being of other metal. Malic acid acts very quickly on lead, and it seems there should be some iron on this type of article for use with cider or other drinks liable to act and cause trouble. The ironmonger from whom the tap was obtained said he had sold lots of these taps and had, in fact, supplied the farmer from whom my patient had obtained his supply. At this time of the year, when supplies of cider are being taken in after cider-making is over, it does seem that this tap may be the cause of no little trouble.

Calcium Lactate as a Muscle Tonic

Dr. G. P. BARFF (Holyhead) refers to a previous letter of his, published in the *Journal* of March 9th, 1929, on the above subject, and describes the case of an ex-athlete, aged 73, who sustained a remarkable improvement in his muscular development and tone as a result of calcium lactate therapy. He writes: I am of opinion that the constructive changes brought about in muscular metabolism resulted from prominent articles of his (the patient's) spare and regular diet containing synthetic products of human milk, or products similar to those formed by the suckling infant during the course of infantile digestion. He adds: I see no reason why the shrinkage of muscular tissue, usually associated with the last stage of life, should not be eliminated by reconstructive measures taken in time. Further particulars can be supplied to anyone interested, on application to Dr. Barff, Trigfa, Four Mile Bridge, Holyhead.

Fractured Spine Caused by Strain

Dr. ALFRED A. MASSER (Penistone) writes. The following case of fractured spine following a sudden muscular strain may prove of some interest to your readers. The patient, aged 47 years, was employed as a clerk till April, 1932, prior to which date there was no history of any injury whatsoever. One morning during that month he was called upon to help unload some heavy bags of money from a taxi outside the office. While lifting a particularly heavy bag from

the ground, he suddenly felt something snap in his back, and collapsed on the floor. He says that he felt the use go out of his limbs below the waist for a few moments, but this passed off, though he still complained of a severe pain in the lumbar region of the spine. After resting for a little while in the office he was able to travel home by bus unattended, having fastened his belt firmly round his waist. He continued in bed for three weeks, and after another month's convalescence he returned to work. He continued his employment for twelve months, apparently in good health, except for occasional pain in the lumbar region and a jarring sensation down the spine on walking downhill. In view of the persistence of the pain he sought medical advice, and on x-ray examination a fracture of the body of the third lumbar vertebra was reported by the radiologist. The nature of the accident as the cause of a fractured spine, and his ability to travel home by bus shortly after it had occurred, appear very unusual, and his continuation at work for twelve months with an ununited fracture of the spine seems worthy of note.

Identification of Glass by Ultra-violet Rays

Dr. FRANK W. MARTIN (Forensic Medicine Department, Glasgow University) writes: Samples of glass, all similar to the naked eye, when exposed to filtered ultra-violet light sometimes show great variability in the colour of the fluorescence. Symons (*Police Journal*, vol. iii, No. 2) has drawn attention to the fact that glass may be identified by exposure to filtered ultra-violet light. I was recently able to prove the accuracy of this statement. In a "smash-and-grab" raid in a large city some time ago a man was arrested for breaking the window of a public-house and stealing a bottle of whisky. On the shoulder of his jacket were two small splinters of glass. The writer was asked by the police to try to identify these splinters of glass with glass from the public-house window. The window in question was made up of two kinds of glass, clear and frosted. Samples were obtained of both, and these, along with a large variety of pieces of glass unconnected with the scene of the raid, were submitted to the fluorescence test, and the result compared with the fluorescence of the splinters on the accused's jacket. From the fluorescence colour exhibited it was possible to state that one of the splinters from the public-house window and the two splinters were of the same make. While it is not claimed that this is absolute identification, it was accepted in court as good presumptive evidence.

Prevention of "Steaming" Glass

Dr. J. ROLAND MURDOCH (Liverpool) writes: A preparation, "Cee-all" (anti-steam), has recently appeared on the market for use in keeping motor-car mirrors and screens perfectly clear in fog or rain. I have found it of service when applied to laryngeal mirrors, as it saves time in dispensing with the necessity for heating the mirror before use. It may be of service to surgeons who wear eyeglasses in the operating theatre. One drop of this preparation is smeared over the glass and afterwards polished off with a clean dry cloth. One application lasts for many days. The label bears the name of O. R. Rowlands, chemist, Wallasey, who is, I presume, the maker.

Corrigendum

The writer of the appreciation of Dr. David Inglis (November 17th, p. 923) misquoted Horace. The passage (*Odes*, 2, 16, 26) should read: "... amara lento temperata nix." The learned correspondent who points this out suggests that "an apology to the genial shade of Horace is indicated"—and we agree.

Messrs. H. K. Lewis and Co., Ltd., submit a specimen of their serviceable ante-natal record card for use with the card index system, size 8 in. by 5 in. Their new "systems" catalogue, also received, describes the many different applications of card indexes and vertical filing systems of use to medical practitioners for book-keeping, case-taking, etc. A very full range of cabinets and cards is offered.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 48, 49, 50, 51, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum-tenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 255.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, DECEMBER 1st, 1934

INTERNATIONAL ACTION TO CONTROL THE SPREAD OF INFECTIOUS DISEASES*

BY

SIR GEORGE S. BUCHANAN, C.B., M.D., F.R.C.P.

A conviction that international co-operation for the control of the spread of infectious diseases deserves to be better known among public health workers than it often is—or at least to be appreciated in better proportion—has led me to address you on this subject this afternoon. In effect I would invite you to inquire with me into the progress made by international methods in the post-war years, and what those methods are. It will not, I hope, be too dull or profitless an inquiry.

In recent years we have come almost imperceptibly to increase co-operation with fellow workers in foreign countries and in other parts of the British Empire on almost every technical subject. Whether it is economics, trade, air routes, water problems, athletics, or what you will, we cannot go far before asking ourselves how they manage the matter, say, in America, or in France, or in Italy, or in the Dominions: Do they do things our way? Have they a better or a worse? Are we cutting one another's throats? Are we pulling together or can we pull together to mutual advantage? Health questions are no exception in this respect. The cosmopolitan tradition has always been strong in medicine and in public health. It was long ago embodied in the Red Cross, and we know what that meant in terms of curative treatment for friend and foe alike during the war. Some of my audience will remember how closely mutual action for disease prevention brought the allied forces together at that time; nearly all will have personal knowledge since then of the advancement effected in some health subject or other by consultations in which nationality and race have hardly needed to be thought of.

To take a non-infectious disease, cancer: it was four months ago at Zurich, in German-speaking Switzerland, that I found myself at a busy and well-organized international congress at work on its radiotherapy. The physicists, radiologists, physicians, and surgeons one met there had come not only from Central Europe but from all parts of the earth to do common work and to make friendships. The cause was the thing, and for them put completely into the background the happenings in Austria and in Germany during that historic fortnight between July 20th and August 3rd. It was, in fact, a big cause and an enduring one. If radiotherapy offers our best method of curing many forms of cancer, and if the philanthropists and the health authorities everywhere are to provide it and spend vast sums of money in obtaining it, the proofs must be offered, the methods declared, and the results estimated. The last is no easy task for cancer, where it must be made a condition before expounding results that the treated cases have been followed up for at least five years to ascertain if the patients die or if the cancer has recurred, and it cannot be done at all without a close

understanding between the workers on the use of terms and on the practices followed.

None of this, as things are now, is within the compass or resources of the workers in a single nation. The big radiotherapeutic work is being done, in different ways, in a few institutes which are scattered all over the world. The Zurich congress had not met for combat between them, but to learn what each had done and is doing, and, as a preliminary, to secure that all successes and failures are observed and reported so that they can be understood and compared. It is a good topical example of voluntary co-operation on the international side, successful for the same reasons that national congresses like the present are successful—namely, the possession of an essential subject, thorough preparation, and meetings held at reasonable, not too frequent, intervals. A list I have of such voluntary international congresses on health and medical subjects in different countries during the past year exceeds a hundred. One does not want to exaggerate their significance, or to claim that no work is good until it has been talked about in a foreign capital. But the point to be made is that in these days in almost any expert work the element of international consultation is required sooner or later, and that we have come almost imperceptibly to accept its necessity and to welcome it.

International Health Organizations

What I have said so far relates to intercommunication—the international congress is only one method—arranged voluntarily between individual workers of different countries, helped, as they often are, by the authorities which they serve or by world health agencies, of which the Rockefeller Foundation is the chief. But the same tendency towards international consultations and understandings has in recent years been evident in the health work of national Governments, and it must be remembered that now in some countries, such as the U.S.S.R., every medical and every public health activity is State-organized and State-directed. This has largely been brought about, or at least facilitated, by the League of Nations, through its Health Organization. The Covenant of the League contains an article [Art. 23(f)] which states:

"Subject to and in accordance with the provisions of international conventions existing or hereafter to be agreed upon, the Members of the League . . .

"(f) Will endeavour to take steps in matter of international concern for the prevention and control of disease."

This obligation of States members of the League has from the beginning been taken seriously. The Assembly votes a substantial annual health budget for its Health Organization, which consists of a medical director and a technical health section of the Secretariat, aided by a committee of health experts of different nationalities.

* Address to the Public Health Congress, November 19th, 1934.

During the last twelve years a great variety of public health and medical subjects has been taken up internationally by this Health Organization. This can be illustrated easily from the world map, which recalls in some places missions to countries asking for foreign experience in the organization of their health services (notably the Balkan States and the Republic of China); in other places meetings of experts on particular subjects such as malaria, leprosy, and sleeping sickness, or the "interchange" visits, with which British medical officers of health are especially familiar. To these must be added particular conferences, say, on cancer statistics, or on the standards and definitions to be adopted for serums, vaccines, and vitamins. The League work also includes the powerful aid to knowledge of epidemic diseases in the Far East provided by the Far Eastern Bureau, which it maintains, largely as a result of Japanese initiative, at Singapore, and to which I will allude again in a moment.

I cite this work of the Health Organization at Geneva not so much because of its bearing on my theme this afternoon, which is international control over the introduction of infectious diseases, as for the example it gives of the international collaboration going on in other fields. Most of the Geneva work has had the advantage of new ground to occupy. It is otherwise with international measures for the control of the introduction of infectious diseases, which have behind them some centuries of tradition, and have been the subject of active international or diplomatic interventions from time to time ever since the plague periods of the Middle Ages. Some of these traditions are strong, and in many places continue to govern the national practice. Some, it must be admitted, are, or until quite recently have been, quite out of date when modern knowledge of the causation of epidemics and modern methods of intercommunication are considered.

Here, therefore, progress in reform and rationalization is by no means easy. It cannot be rapid or be dealt with by short cuts. It has, however, been a notable and encouraging progress, which will bear comparison with the newer type of international work. Some of it has been effected through the new machinery of the League, but most is done through the earlier established International Office of Public Health, which was set up in Paris under the Rome Convention in 1907, and has since had various new duties added to it by subsequent international agreements. This body, often better known as the *Office International d'Hygiène Publique*, since its official language is French, has various ties with the Health Organization of the League to avoid overlap, and, if the League of Nations' spirit consists in working for and obtaining international understanding and camaraderie, it works, side by side with the League, fully in that spirit.

First Public Health Services

Sanitary organization for the defence of frontiers, which at ports meant quarantine services, was among the earliest, if not the first, of the services established in the name of public health. The largest organized State public health service in the world, that of the U.S.A., sprang from frontier defence, and still depends upon it. Our own State medical services were at the beginning deeply concerned with quarantine, and started with the cholera menace of last century. Only the other day a new Government, the National Republic of China, decided to set up an effective port sanitary service as a preliminary to the organization of its internal public health administration.

Owing to modern knowledge we need have far less apprehension than used to be the case of the results of the mere importation into a country of a disease to which we are strangers, and it is unfortunately true that many of the worst infections—*influenza*, for example—will defy

all frontier measures. Our recent tendency with many epidemic and endemic diseases is to rely more on immunization, on specific curative treatment, and on general measures of hygiene, such as the prevention of overcrowding, than upon mere defence against the introduction of, or exposure to, the infection itself. One can conceive, indeed, that by another generation or two frontier defence against infections may almost come to be disregarded in view of other available measures; a time when we could be content, and the public we serve would be content, to disregard even the importation of cases of major smallpox; to accept the arrival of the plague-infected rat, or the dog which may be incubating rabies; to chance the anthrax-infected shaving-brush or the psittacosis parrot—always in confidence that, if these or any other infections come into the country, local action will circumscribe and extinguish them, and local action will suffice.

But if this time is to come, it is not here yet, and I do not see local authorities asking for it. We may not place as much value as we did on protection against exposure to infection, but at least we expect to have that protection provided when it can effectively be exercised. For home administration this is a truism: at home we insist on maintaining disinfection, hospital isolation, and many other measures to keep people from exposure to infection, sometimes even at a greater cost and effort than a strict sense of proportion would warrant. In the case of importations from abroad parallel action must be maintained, and is expected. If defence against the introduction of infections is only one of the measures required, defence there must still be.

Now in the past, and indeed until quite lately, defence was usually the only measure thought of. If you are interested enough to study the literature of what was called the Levantine plague or of cholera diffusion—you will find much of it epitomized by Simon and in the Local Government Board Medical Reports, and more recently by Professor E. W. Hope in his book on *Health at the Gateway*—you will soon appreciate how ruthlessly, from the seventeenth century well into last century, these national self-protective measures were applied.

Early Port Sanitation

Leaving aside land frontiers, it was common practice at seaports for passengers and crews, sick and healthy together, to be kept in isolation for weeks in the cramped space of the ship at a quarantine anchorage or be herded into lazarets on shore, or for the ship to be incontinentally repulsed to any other port in which it could find refuge; or for merchandise to be destroyed wholesale and ship-owners ruined because the ship had come from a port where pestilential disease was suspected to exist. It was from this aspect, inhumanity and restraint of commerce, that international agreements about infectious diseases came to be made. The formal International Sanitary Conventions on the subject, which started in 1892, were directed far less towards joint action for controlling the spread of disease than to getting rid of the intolerable administrative position created by the working of the individual national defences. Enormous diplomatic energy was for this purpose expended in the successive pre-war International Sanitary Conventions, up to and including that of 1911, and they were not unsuccessful. They limited the detention of ships and passengers and freed the cargoes. They gave port sanitary authorities a defensible code of action to work upon with medical authority behind it, and helped to make them, at least in this country, the practical bodies they are. But to understand these international agreements you must think of them as being essentially of the nature of armament conventions which limit the range and calibre of the guns per-

mitted, rather than the occasions on which the guns need to be let off.

It has not been an easy task to intrude into this elaborate defence-regulating system new methods of international co-operation directed against the diseases themselves. When dealing with infections every administration has a traditional, as well as a natural, prejudice to rely solely on those measures which are wholly in its own control, while in many countries age-long legislation and practice have been based on the conception of this being the only line that a responsible authority can accept when it has to protect its own nationals.

We have, nevertheless, gone some way on the new lines and found them profitable, using as the chief instruments, first, the remodelling of the International Sanitary Convention effected in 1926, and secondly, the International Health Office at Paris, which has a permanent committee of technical officers representing nearly all the nations of the world, and includes a quarantine commission that regularly keeps the practical application of this important Convention under review.

Rat-plague Infection After the War

Let me take, as a good example of the change over, the spread of plague by the carriage of plague-infected rats on ships. When port sanitary authorities, old and new, got to normal work after the war they found that the spread of rat-plague infection from port to port by means of shipping had become a rather formidable affair in many parts of the world. When a rat-plague infection was introduced it could, in some circumstances, cause a considerable prevalence of human plague; even if it did not, the continued presence of epizootic plague among rats in the port had definite dangers and inconveniences, and its existence was naturally considered a reproach to the local sanitary authority and the health administration of the country. Many ports had attacked the position energetically, and they were encouraged to do so by the efficiency with which rats on shipboard could be destroyed by new fumigation processes—notably, by hydrocyanic gas in one form or another. It came about, therefore, that on the basis of individual port defence ships had only to go from, or to have touched at, ports in plague-infected countries for the authorities of the port visited to require them to be submitted to fumigation processes which, besides being costly to the shipowner, were as often as not unjustified by any evidence of the existence of plague-infected rats on the ship.

Now so long as this extreme measure of defence was only adopted in a few ports and on a few sea routes, it was accepted without much protest by shipowners, but when the ship, from the mere fact of having at some time or other during the voyage been at a plague-infected port, had to be fumigated again and again at many subsequent ports, the position became intolerable for the shipping trade, and, once the possibility of international co-operation was admitted, it was impossible to justify it.

Successful Measures for Its Control

The system which is now adopted is a really co-operative one. If there is actual plague infection on the ship it must, of course, be dealt with at once. But what we have now done is simultaneously to go for the root of the trouble—namely, the ship rat itself. Every six months, according to present international practice, a ship has to be properly overhauled at one of the recognized ports (there are now over 400 of them available throughout the world) to ascertain whether she harbours rats. If the inspection shows that does so, deratization by fumigation or by any other effective means is required. Other ports then recognize what has been done on the production of certificates carried with the ship's papers.

The whole system is regulated by the 1926 Convention itself, and its working is subject to periodical survey at Paris by the Permanent Committee of the International Health Office. It has now been in operation for seven years. Naturally it has not been established without anomalies and hard cases arising, but when they do there is machinery for their investigation and representation to the Government concerned to prevent their repetition. And, in fact, we find such cases get fewer year by year. The system has the full sympathy of shipowners, who now know what is expected of them in this respect, and on their side have come to realize how much can be done on the ship itself to avoid fumigation by making the ship, as it is termed, "rat-proof." A notable example of this tendency was lately furnished by a report, made by the joint committee appointed by the Chamber of Shipping of the United Kingdom and the Liverpool Steamship Owners' Association, where the essentials of rat-proofing are laid down for the guidance of shipbuilders.

That all these measures have enormously diminished the rat-infestation of ships is indubitable. They need to be supplemented, more than at present, by rat-proofing and rat-destruction at certain docks and warehouses, but if both continue as they are doing the object will soon be achieved. Plague will continue in certain regions of the world, but it will no longer be a disease of world diffusion. Its lines of communication will have been effectively cut. I could give you no more striking example of the advantages of combined international action supplementing, or even ultimately superseding, individual national defence.

The same principle has been applied in different ways to other diseases, notably to cholera, which, if it follows its usual epidemic cycles, will require special attention next year. Here we have secured a common recognition by all countries of precautions taken in the cholera-infected country, including anti-cholera vaccination. Of yellow fever I will speak in a moment in connexion with aircraft.

Varola Minor in England and Wales

I may dwell for a little while on the importation of small-pox, in view of the interest which all local authorities represented here have in dealing with that disease. Let us consider small-pox for a moment from the British end. The two epidemiological types of small-pox, *variola major* and *variola minor*, are now well understood, though both of them remain, and rightly, notified and notifiable under the term "small-pox." In most parts of England, though happily not in Scotland or in Ireland, we have, since 1922, become habituated to local prevalence of *variola minor*, the kind of small-pox which practically stops with the first characteristic rash, does not go on to the secondary fever or pustulation, leaves little or no pitting, and causes an almost negligible mortality and usually only a brief period of real illness, if any, to the patient. From 1922 to 1933 we had no fewer than 81,061 such cases notified in England and Wales. Regarded simply as small-pox, the number of small-pox cases in this country has been relatively far higher during this period than in any part of the Continent, with the possible exception of Soviet Russia.

Besides this we have the fact that the severe epidemic type of small-pox, *variola major*, exists and persists in Eastern countries—a notable epidemic of it occurred in Alexandria in the early months of last year—in which none of the characteristics of small-pox which have made that disease so much to be dreaded are absent. There is the heavy toxicity, the severe mortality—I am, of course, referring to persons unprotected by vaccination—the pitting, the scarring, and all the rest. If this infection is imported into this country it breeds true; in other words, it is the small-pox with which we were only too

well acquainted in 1893 and 1902. That it can do so has been proved by several examples of its importation by persons coming to England or Scotland in the incubation stage, or when the importation has been by cases that were missed at the ports. We are able to deal with such cases before they get much hold on the local population by strict measures of isolation, by surveillance of contacts, and by vaccination. The success of our practice in this respect, thanks to our system of central intelligence and the vigilance of local authorities, is well known and needs no restatement; I find that it constantly brings us credit when described to my colleagues of other countries. But it is a formidable and costly business for local authorities. The importation ought not to happen, if it can possibly be avoided.

This being the case, we have had, during recent years, to ask two things of the health administrations of other countries. The first was that they should recognize our epidemic variola minor, a differentiation on which we ourselves took—and needed—some time before we could make up our own minds. If you put yourselves in the position of the European countries you will realize that they, with no experience of variola minor, required some convincing. Apart from Switzerland, which had had an experience of the mild epidemic type of small-pox very close to our own, the Continental countries knew small-pox only in its classic or major epidemic form, and knew it from fairly frequent importations—in France, for instance, from her African possessions. When these importations took place and epidemics of small-pox occurred the health authorities applied drastic measures for their extinction, including obligatory vaccination of persons in the infected regions or entering other regions from infected areas. They had every right, confirmed by the text of the international agreements, to treat in the same way arrivals from a foreign country in which small-pox was epidemic. These arrivals should satisfy them of their immunity by producing evidence of recent vaccination, or should be vaccinated.

Episode of the Ship "Tuscania"

Even as late as 1929 the question came to a head by the episode of the ship *Tuscania*, which many of you may remember. For reasons I need not go into, the *Tuscania* landed at British ports forty-five persons actually incubating small-pox of the major type, who developed the disease in this country, nine of them dying from it. Our system of notification of contacts and surveillance was so good that no more than six secondary cases occurred; in other words, the whole group of variola major cases in the country only totalled fifty-three, all duly isolated and controlled. But the incident had become good newspaper copy all over the world, and at once the fact of our ordinarily having at the time a hundred or more notified cases of small-pox in England every week was mixed up with it. Variola minor was taken as a mere term of camouflage. England was a country in which small-pox was epidemic, and vaccination and other measures must be applied to those coming from it. For a while this was the view taken at French ports, and much inconvenience resulted until the situation was cleared up.

As a digression, I may say here that this foreign action had nothing to do with the English Vaccination Acts. It would not have mattered whether those Acts had or had not a conscience clause, or did not exist at all. The English Vaccination Acts, so far as they apply compulsion, relate only to the vaccination of infants. What the foreign countries were concerned with was the vaccination of the travelling adult. The international understanding on this point is that it is only vaccination within three years which counts in the case of arrivals from a small-pox-infected area. It is perhaps as well to

point this out, as the question of "international reprisals" has, I think without sufficient warrant, been introduced into some of the discussions about our own vaccination legislation.

Recognition of Two Epidemic Types of Small-pox

Apart from the *Tuscania* incident, no inhibitions have been imposed abroad upon travellers from England on account of the considerable small-pox prevalence of recent years, and another *Tuscania* incident now would not have the same consequences. The characteristics of our variola minor are now well understood in all responsible quarters, and this has been brought about in large measure by the system of international co-operation which the Post Office provides. If you have your facts, and can bring them twice a year before a committee of critical official technical representatives of every country interested, and can reply to their questions and get their experience, the administrative position is bound ultimately to clear, at least if you have enough persistence. In this case the Permanent Committee of the Office International d'Hygiène Publique, beginning with many doubts and hesitations on the question of stability of epidemic type, collected, session by session, the facts of past epidemics—for example, in Australia—and of the actual distribution of small-pox at the time. Though Europe was not generally familiar with it, extensive epidemics parallel to our own were going on in the United States and elsewhere, persistently mild in clinical type, of lower power of spread, and tending to natural extinction after three or four years of local prevalence. There emerged a mass of evidence, well put together for us by the delegate for Portugal, Professor Ricardo Jorge, on which the differentiation of the two epidemic types, major and minor, could be accepted both for scientific and, if need be, for administrative purposes. With this authority the two terms were embodied in the last *International Nomenclature* of causes of death, as also in the last official *Nomenclature of Diseases* issued by the Royal College of Physicians of London. They now govern the national precautions which we decide to take, and we know where we are.

If I have dwelt on variola over-long it is because of the advantage of presenting you with a good concrete example to show how one side of the international work is done.

Work on Other Infectious Diseases

The same system is habitually applied to other infectious diseases where the great necessity is to have prolonged international epidemiological study. It is in this way that the Permanent Committee of the Paris Office dealt with the discovery of that rare condition called *post-vaccinal encephalitis*. It was as invaluable to Holland and to two or three other countries as it was to ourselves to pool experience with a view to determining the circumstances of age, vaccination, etc., which were associated with this newly understood complication of vaccination. You will find abundant evidence of the practical use made of these studies in the reports of the English Departmental Committee on Vaccination.

The occurrences a few years ago, in several countries, of a virus disease contracted from parrots received similar international study with great advantage, since we were not only able to collect information bearing on the origin and causes of *psittacosis*, but also to settle between ourselves the advice which should be given to our Governments regarding the exclusion of parrots or attempts to control their importation. No one country wanted to be the dumping-ground of parrots which other countries refused to take. So also with *undulant fever*, which used to be called Malta or Mediterranean fever, as soon as it was ascertained that it could be prevalent in Northern

Europe. The warning of its prevalence in Scandinavian countries, brought to the table in Paris, led to inquiries here by the Ministry of Health, on which much of our present understanding and recommendations about this disease have been based. I could continue the list, mentioning particularly *cerebro-spinal meningitis*, on which information about prevention or treatment comes up to the Paris sessions year by year, and gives each of the delegates something new to take back and work upon. All inquiries of this kind ultimately appear in the *Monthly Bulletin* of the Office International d'Hygiène Publique, which represents one of the most solid contributions to the science of epidemiology which we possess to-day.

An International Intelligence System

To illustrate another side of the international work I go back to small-pox and to the second English requirement—namely, to keep down importation of small-pox from countries where the severe type is prevalent. Here we have to encourage all measures taken in small-pox-infected countries to prevent the embarkation of infected persons, and to know if particular ships are likely to be carrying small-pox cases or contacts, without complicating our administration with a mass of unnecessary inquiries at the port of entry, or, subsequently, in all parts of the country in order to keep particular individuals under daily observation until the incubation period is up.

For this day-to-day administration a system of international intelligence is essential. The work done here goes on independently of the six-monthly discussions in Paris which I have just described. We are dealing with intelligence about epidemic occurrences rather than with epidemiology. Under the terms of the International Sanitary Convention, 1926, the occurrence of new outbreaks of small-pox, cholera, plague, typhus, and yellow fever in different parts of the world is to be made known at once to the different health administrations, and followed by information about their progress. For this purpose the Convention provides for immediate notifications to the International Health Office in Paris, which transmits them to the various Governments concerned. By a further provision of that Convention Paris is able to work regionally in this matter, for a large part of the East, through the Far Eastern Bureau of the League of Nations at Singapore; for the Near East, through the Quarantine Board of Egypt; and for the Americas, through the Pan-American Sanitary Bureau.

As compared with the conditions which obtained before the 1926 Convention, the results are certainly satisfactory. The countries for which we have still to depend wholly on consular information are few. For countries as a whole it can be said that neither with small-pox nor with other diseases dealt with in the Convention is there anywhere any notable inclination to withhold information or to delay its transmission. Telegraphic codes and wireless messages, including wireless telephoning, are freely used. Indeed, if any reproach can be brought against this service it is usually either for an excess of activity in sending telegraphic or wireless messages about occurrences which, except possibly to their immediate neighbours, can have no administrative interest in other parts of the world, or when, in addition to transmitting the official communications received from the health departments, some of the international bodies add their own commentaries.

To meet these objections the Paris office has lately done a good deal to encourage direct local communications between neighbouring countries and from port to port. A recent agreement has been made, for example, to cover all the North Sea area, by which port medical officers of the different countries, including the United Kingdom, communicate direct with their opposite numbers abroad where any special risk has been noted. Again, we have

special arrangements with the Suez Canal health authorities and with Marseilles about small-pox on ships bound for English ports.

I mention these details only as an indication that the intelligence system which now obtains, effective as it is, always requires attention. No doubt there will be some revision and simplification of it when another international sanitary conference is held. The important point now, however, is that as a whole it is working very well and producing the results desired. In this it affords a striking contrast to previous methods. In the earlier years, when we worked not on co-operation but on the system of regulating our mutual defence against one another, everything depended on the declaration of ports as "infected," and such declarations were often made in a most arbitrary fashion. The label was put on and taken off often for quite unsubstantial reasons, and there was every inducement to avoid having it put on at all. It was not until 1926 that the international convention explicitly stated that information about the occurrences of infection at a foreign port was merely to be taken as a guide to the extent of inspection or inquiry necessary on the arrival of the ship, and that it was the condition of the vessel itself which should determine the quarantine measures taken.

Present Position Concerning "Bills of Health"

So, too, this co-operative international system of intelligence about epidemics has removed almost the last vestige of reason for the traditional document carried by the ship called the "bill of health." The bill of health records that a particular port has been free or otherwise from pestilential diseases at the time the ship was there, and every owner and ship's captain has been brought up to consider it as one of the most important of the ship's papers which they have to produce.

Dating as it does from the period when no country would be satisfied with statements from another without confirmation from its own representative, these bills of health have to be seen, stamped, and viséd by the consul of the country which the ship is going to visit. This does not apply merely to the original port of departure of the ship, but to every other port at which it calls and in relation to every port at which it proposes to call. The delay in the ship's time and the cost of the bills and fees are very considerable. The practice was so consecrated by centuries of use that it had never been assailed in any international sanitary convention before that of 1926, when, for the first time, an article was inserted by which the signatory Governments undertook to take any practicable measures to dispense with the consular visa and ultimately with the bill of health itself. The article was by no means a strong one, but the Office International d'Hygiène Publique has kept it to the forefront by efforts to secure local agreement between different nationalities on the subject.

Lately, in the *British Medical Journal*, attention has been forcibly drawn to the inconveniences of the system; to use no stronger term, by a ship surgeon, who quoted some extreme instances of the waste of time and money it involved. I trust that with patience—for it requires patience to deal with deep-rooted sea traditions—their number can soon be diminished. Governments have now before them an international agreement for dispensing either with visas or bills of health, or both, for ships of their respective nationalities, and there is every reason to believe that this agreement will receive the adhesion of most of the important maritime countries of the world. Here it is the shipowners who stand to benefit, and one may expect them to do all they can themselves to support the efforts which the hygienists are making to get rid of proceedings taken in the name of health but bringing no advantage to it.

Importation by Aircraft

Lastly, I must add a few words about the importation of infectious diseases by aircraft, since, with any sort of vision, we must appreciate a growth of air routes and air lines which will make them as ordinary and as much used for travel from distant countries as sea and land routes. Already the world air routes are considerable, although the total number of passengers carried is but a small fraction of the whole. Already we have had demonstration that they can carry infections, and that passengers from one non-malarious country to another can contract malaria in course of an ordinary air journey from the bites of infected mosquitos on the aircraft.

Air flights are so short in time that they mock at incubation periods, and rarely allow initial symptoms to occur before the aircraft reaches its destination. If the notion is now out of date and usually futile of putting passengers by sea, and the ship they go in, under special observation for no other reason than that the ship has touched at a seaport labelled as "infected," how much more futile is it when applied to airports! Blindly following precedent, some countries have, in fact, demanded that the commander of the aeroplane must, as a condition of landing his passengers or crew, produce bills of health, attested in each instance by the appropriate consuls, to show that every place of embarkation on the air route was free from plague, cholera, or other maladies. How seldom could this procedure ever be a guide to the discovery of dangerous persons or infected articles? The whole matter has had to be taken on a wider basis, with all the help that the Air Ministries and air lines, and particularly the International Commission of Air Navigation, could give us, and with separate consideration of the natural history of each disease with which we were able to deal. If for us in this country Eastern small-pox is the chief importation to be guarded against, in the tropical and subtropical parts of the world, where the *Stegomyia* mosquito is common, it is yellow fever. This disease now could easily be imported through air traffic by infected persons or insects into countries where yellow fever would have all the opportunities of spread possessed by a new disease which is introduced into highly susceptible populations.

A Sanitary Code in Aerial Navigation

The International Sanitary Convention for Aerial Navigation, signed at The Hague last year, was hammered out at the International Office of Public Health in order to meet all the chief contingencies of transmissible and preventable infections, and to provide an international code of conduct—on the one hand something practicable and reasonable from the side of air traffic, and on the other something which, when it had to be applied, would offer a substantial security without illusory formalities. This convention deals, naturally, with the action to be taken if infectious diseases occur on aircraft, and with those insanitary conditions *en route* which require an international understanding to deal with—for example, the throwing out of excreta.

The guiding rules for special diseases are particularly detailed in the case of yellow fever, and have been drawn up with the aid of the experience of America as well as of Africa. In regard to the detection of persons arriving in an infectious state from any disease, we have two key positions. The first is that the airports open to arrivals from other countries are, for political and customs reasons, few. It is thus not difficult or costly to see that they are provided with the necessary nucleus medical service, able to deal with an infectious case, and with

access to hospital and laboratory; able to supervise the health of the personnel of the aerodrome and its cleanliness; able also, when circumstances require, to make necessary interrogations regarding the recent movements of particular persons coming from distant countries and exposed to particular infection, and so to secure the same surveillance of them in the places on land to which they go as would be imposed if they had arrived at a seaport.

In this country the co-operation of the local authorities and medical officers concerned has already been secured for this purpose. The second key position, without which the first would be useless, is the existence of the international intelligence system about the chief preventable diseases which I have already described. Without it no rational or tolerable system could have been devised; with it we may reasonably hope that the agreement is one which will help and not hinder both the national health authorities and the interests of air passengers and air lines.

The wide acceptance it has already received, and the advantage which it has even at this early stage been shown to possess in dealing with yellow fever in Africa, are good auguries for the success of the Convention. Of course, where conditions change so rapidly as they do with air travel, no code of conduct can be expected to be complete once for all; the Convention itself contains provisions for its amendment as the result of experience, and its working is already being reviewed regularly by the Permanent Committee of the Office International d'Hygiène Publique, which reports on it to all the Governments concerned.

Co-operation of British Public Health Officers

If time permitted I should have been glad to add details of the International Agreement of Brussels providing for treatment of venereal diseases in seaports; as it is, I mention it in passing as an important section omitted. I trust, however, that even with this omission I have not selected the examples so badly that a representative audience of British local authorities and medical officers of health will think of my subject as too remote from their own practical work. I cannot think it is so; the daily work of public health departments and their officers on the prevention of communicable diseases cannot help being affected by the results of these regular international studies and pooling of experience. In this matter what I have said about small-pox, plague, undulant fever, or psittacosis would apply to many other diseases. If the results are not brought to public health officers directly, through the *Bulletin Mensuel* of the International Health Office, or through the *Quarterly Journal* of the Health Organization of the League of Nations, their lessons are considered and incorporated in circulars and reports from the Ministry of Health or other central Departments, and presently come into the stock of the accepted technical knowledge on which our health authorities work, whether they are central or local.

Local authorities and public health officers sometimes can help the work materially. It may be that, as in a recent international inquiry about disinfection, in which the medical officers of health of several of our larger local authorities were good enough to participate, the information to be had from other countries in return for the trouble of answering an interrogatory sometimes is not, and could hardly be expected to be, of much use to ourselves. But often the boot may be on the other leg, and I venture to express the hope that when information is asked of local authorities for international health purposes it will never be grudged. There is much to take as well as give.

Results Obtained without International Dictation

If you ask me to go further and end by specifying in some conveniently quotable figures what this international system has saved the country in the way of avoiding importations of infectious diseases, I fear I must be disappointing. It is impossible to estimate events which have not occurred. Even if it were attempted the increased individual efforts and efficiency of our own port sanitary authorities in recent years, as well as changes in epidemic characterization, would have to be weighed in with the international factor, and responsibility apportioned between the three. But at least the extreme rarity of these importations, notwithstanding modern facilities of communication, when contrasted with the experiences of the end of the last century and the pre-war period, in which we relied almost wholly on our own "defence" measures, is some testimony to the value of the willing international co-operation I have outlined. I would insist on its willingness; in my experience the best work has been done by avoiding any semblance of international expert dictation, any suggestion of international inspection, or any interference with national administration. It has been achieved by working steadily for conferences and agreements between responsible health officers throughout the world, determined to help one another to carry out their respective national duties.

THE TREATMENT OF ADOLESCENT KYPHOSIS*

BY

JACQUES CALVÉ, M.D.

CHIRURGIEN-CHEF DE L'HÔPITAL FRANCO-AMÉRICAIN DE BERCK-PLAGE

The danger against which the orthopaedic surgeon must fight in adolescent kyphosis is the spontaneous formation of compensatory lordoses in the cervical and lumbar regions. This is true of all types of the deformity, whether due to late rickets, sometimes called "kyphotic disease" and characterized by an osteomalacia of the dorsal vertebrae with a poor general state of health, a type that may be called "somatic kyphosis"; or whether it is the painful adolescent kyphosis, which is a special disease of indeterminate nature, regarded by some (Schmorl and his pupils) as connected with a subcartilaginous nuclear hernia, by others (Schauerbach, Sorrel, and Delahaye) as with epiphyseal trouble, and by others again (Calvé, Galland, Meyer, etc.) as connected with nuclear hernia combined with epiphysitis—a kyphosis of disk origin as opposed to the preceding type. This orthopaedic principle applies whether the kyphosis is capable of being actively and passively reduced—that is to say, a kyphosis due to bad posture—or whether it is irreducible with a certain number of dorsal vertebrae attacked by definite lesions, forming, as in Pott's disease, an actual focus. The aim of this short paper is to show why, in adolescent kyphosis, spontaneous lordoses form: why they are harmful; how they can be avoided; and by what they should be replaced. First of all it is necessary to recall several essential points in the normal and pathological physiology of the spine.

Movements of Flexion and Extension of the Normal Vertebral Column

Ignoring, for the moment, lateral, rotary, and twisting movements, the vertebral column can be divided into (1) regions of hyperextension, and (2) regions of flexion.

* A communication to the Section of Orthopaedics at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

There are two regions of hyperextension: the cervico-dorsal, and the dorso-lumbar and lumbar region. As shown in the attached diagrams, the cervical spine with the three first dorsal vertebrae form the principal region of hyperextension—that is, a region in which the vertebrae as a whole allow quite a pronounced movement of hyperextension, very pronounced in certain persons who can touch the upper dorsal spine with their occiput. On the other hand, this region allows little or no range of flexion. The dorso-lumbar and lumbar region includes the ninth, tenth, eleventh, and twelfth dorsal, and the first, second, third, fourth, and fifth lumbar. Movements of hyperextension are highly developed here, and, in supple persons, when the trunk is bent backwards the head can be placed between the heels.

(1) Maximum of flexion. (2) Intermediary position. (3) Maximum of extension.

FIG. 1.—Normal physiology of the dorsal vertebrae. Region of flexion: (a) a certain degree of flexion is possible; (b) impossibility of extension.

(1) Maximum of flexion. (2) Intermediary position. (3) Maximum of extension.

FIG. 2.—Normal physiology of the lumbar vertebrae. Region of extension: (a) a certain degree of hyperextension possible; (b) with possibility of flexion.

The regions of flexion are the suboccipital and the dorsal. The movements of flexion which occur at the occipito-atlodian articulation should be considered separately from the rest of the vertebral physiology. They are, moreover, very limited, and play no part in the subject with which we are dealing. There remains the dorsal region, the seat of most of the movements of flexion of the vertebral column in its entirety. There are no movements of hyperextension.

The Disk and the Nucleus Pulposus in Flexion and Extension

This matter, which I have discussed elsewhere, has been the object of some very important research in Germany—research that is very well described in a recent work (Mauric: *The Intervertebral Disk*). It must be remembered that the disk acts as: (1) a nuclear axis through its gelatinous centre—the "nucleus pulposus" (Luschka); and (2) as a true anterior and posterior check ligament through the fibrous ring which connects the intervertebral disk with the overlying and underlying vertebrae (see diagram).

In the regions capable of flexion (mid-dorsal) the nucleus is situated at the junction of the posterior and middle thirds of the disk. The movement of flexion pinches the disk in front and pushes the nucleus backwards to a very slight degree. If the reverse movement is attempted—that is, an effort is made to stretch a dorsal intervertebral disk in front and pinch it behind—failure results. It seems as if, on the one hand, the anterior margin of the fibrous ring acts as a check, and on the other, the somewhat posterior situation of the nucleus in this region prevents the compression of the disk behind. Movement is thus blocked in a position in which the

surfaces of the overlying and underlying vertebrae are parallel. By contrast, in the regions capable of hyperextension, the nucleus pulposus is situated further forward; it generally occupies the middle third of the disk. The disk can be stretched in front and pinched behind. This movement of anterior stretching is especially pronounced in the lumbar vertebrae. If, however, an attempt is made to destroy the parallelism by flexion—that is to say, to stretch the posterior part of the disk—this cannot normally be achieved. The posterior part of the disk acts as a check.

We must remember that this physiology, so to speak, of the vertebral column exists only in childhood, adolescence, and the early years of adult life. Premature senility of the disk, and especially of the nucleus pulposus, appears towards the age of 30, and is generally definitive at the age of 40.

What occurs in the upright position? The normal attitude is such that the line of gravity should fall in the middle of the base of support. The upright position is characterized by a slight cervico-dorsal lordosis, a slight dorsal kyphosis, and a slight dorso-lumbar and lumbar lordosis.

Pathological Physiology of the Vertebral Column

From what has just been said about the normal attitude of man in the upright position, it can be seen that kyphosis is merely an exaggeration of the natural curves. All causes which may increase these curves will bring about a kyphosis—for example, the occupational kyphosis of certain adolescents who are obliged to carry heavy weights on their shoulders and head. Here there is a special malleability of the vertebral bodies (dorsal rickets), which, destroying the equilibrium between the weight and the resistance of the vertebral bodies, constitutes a new cause of kyphosis. Every destructive or pathological modification of the dorsal vertebrae will be a new cause of kyphosis (the painful kyphosis of adolescents, cuneiform deformities of the vertebrae, etc.).

Another cause, which I mean to discuss more fully in a subsequent work, would seem to be a congenital predisposition to kyphosis, and, in my opinion, enough stress has not been laid on this point. This is the abnormal and posterior position of the nucleus pulposus in certain young people. We know that the nucleus pulposus is merely the remnant of the notochord. It is easy to imagine that, in certain cases, this notochord occupies a more posterior plane than is normal.

Be that as it may, a physiological kyphosis is followed by a pathological one. The posterior convexity of the back increases and becomes a prominence. In order that the upright position may still be possible, in spite of this deformity—that is to say, in order that the line of gravity should continue to fall in the middle of the base of support—compensatory cervical and lumbar lordoses immediately and spontaneously occur in the regions which are normally capable of hyperextension.

Why are Cervical and Lumbar Lordoses Objectionable?

In the first place, they are ugly. The neck becomes short, the abdomen prominent, and the dorsal prominence accentuated; this is the hunchback type. Secondly, they are harmful for two reasons: (a) under the effect of weight they become more and more accentuated, and, in consequence, tend to bring about a progressive increase of the kyphotic prominence; (b) a prominence is formed, not only of diseased or deformed vertebrae, but of sound vertebrae, a condition comparable with that of Pott's disease, where, even with a limited focus, healthy vertebrae help to form the gibbus as much in the upper segment as in the lower segment of the latter.

In the third place, when the compensatory lordoses become very accentuated, and this is found particularly in the lumbar region, a considerable expansion of the disks in front takes place, with a true propulsion of the nucleus into the anterior third of the disk. In this position the nucleus acts as a wedge, and blocks the overlying and underlying vertebrae. In this extreme position it prevents a return to the normal. Finally, these lordoses, which fix the vertebral column permanently into a bad posture, sooner or later become the seat of more or less tolerable pain. Every orthopaedic surgeon knows that kyphotics suffer more pain in the lumbar region than in the dorsal.

How can Spontaneous Cervical and Lumbar Lordoses be Avoided and Replaced?

In other words, how can a patient with kyphosis, when he is cured, be given an upright position consistent with the static laws—that is, so that the line of gravity always falls in the middle of the base of support and with a minimum of deformity? The same problem occurs in dorsal Pott's disease; for the spontaneous and natural cervical and lumbar lordoses there must be substituted

FIG. 3.—A, Spontaneous and wrong compensation of kyphosis by cervical and lumbar lordosis. B, In the same degree of kyphosis artificial and correct compensation by therapeutic curves produced immediately above and below the kyphosis.

FIG. 4.

FIG. 5.

FIG. 4.—Irreducible lumbar lordosis.
FIG. 5.—Modified physiology of the dorsal vertebrae after progressive adaptation, needing time and care.

therapeutic compensatory curves situated immediately above and below the kyphosis. To obtain therapeutic lordoses the normal physiology of the dorsal vertebrae must be modified; movements of hyperextension must be brought about at the level of each sound disk.

This involves a work of repair and adaptation which needs time and care. Two procedures are employed. (1) The Minerva plaster jacket and recumbency in an outstretched position and in complete hyperextension. This plaster apparatus, made with the whole spine in extension, blocks the body in such a position that the physiological, cervical, and lumbar lordoses are suppressed and can no longer occur. It is enough then to make a large window at the level of the kyphotic region, and

exercise a slow and progressive correction with the aid of a compression pad, to achieve the desired result in a more or less lengthy space of time. (2) Correction in horizontal recumbency and a hyperextended position. A cast of the shape described by the attached figure can be used, or—and I prefer this procedure—the plaster bed. Whichever procedure is adopted the position of the recumbent patient is such that the lumbar lordosis is completely suppressed, and in the segment of the upper vertebral column, at the apex of the kyphotic deformity, a permanent and progressive straightening force is exercised under the influence of the weight of the upper part of the trunk and head. The action thus taking place can be compared to a permanent pressure on the shoulders.

FIG. 6.—First procedure. The Minerva plaster jacket with window at the level of the kyphosis. Progressive correction with the aid of compression pad (cotton or felt). Impossibility of cervical or lumbar lordosis.

FIG. 7.—Second procedure (the better). Correction in horizontal recumbency and in a hyperextended position. No cervical and no lumbar lordosis. At the same time, and in this position, massages and exercises are carried out.

In my opinion the second method only should be used in an adolescent kyphosis. It permits a number of orthopaedic measures which are indispensable for these patients—that is, in the recumbent position many gymnastic and massage movements can be carried out which develop the muscular system of the young patient, and little by little endow him with a solid muscular corset, which will allow him to maintain the correction when it is obtained. In horizontal recumbency the action of the kyphotic forces is destroyed, and the principal one—weight—becomes, on the contrary, a valuable help.

M. TSURUMI (*Bull. Off. Internat. d'Hyg. Publique*, October, 1934) states that in June, 1933, antityphoid inoculation by mouth was carried out on 32,130 persons in the prefecture of Saitama, near Tokyo, while 45,790 persons in ten other towns served as controls. Up to the end of December, 1933, six cases of typhoid fever occurred among the inoculated as compared with thirty-nine among the controls. One of the six persons fell ill six days after inoculation, which therefore took place during the incubation stage, so that there were really only five cases among the inoculated and forty among the controls.

ALLERGY, METABOLISM, AND THE AUTONOMIC NERVOUS SYSTEM

BY

C. PAGET LAPAGE, M.D., F.R.C.P.

SENIOR PHYSICIAN, ROYAL MANCHESTER CHILDREN'S HOSPITAL, AND
PHYSICIAN TO CHILDREN, ST. MARY'S HOSPITAL, MANCHESTER

My object here is to give you what I consider should be a clinical conception of allergy. In previous papers^{1,2,3} I have led up to this conception. First of all allergy should be distinguished from infection and its reactions. One big difference clinically is that allergic manifestations tend to be afebrile and evanescent, and infectious illnesses febrile and of slower subsidence. Allergy arises from processes which, though initiated by foreign proteins, are primarily metabolic, internal, and autonomic in nature. Infectious illnesses arise from reactions to the foreign invading toxins of bacteria. Allergy must not be confused with immunity. Clinically the first is an irritative and the second a protective phenomenon. Rich⁴ has shown experimentally and quite clearly that hypersensitiveness to bacterial allergens and immunity to the same bacteria can be separated: when the serum of allergic immune animals is injected into normal ones the immunity is transferred, but not the hypersensitiveness.

Bacterial allergy may be connected with infection in that individuals may be infected and become sensitive to the proteins from the bacteria in some septic focus in their own bodies, but this reaction is an irritation phenomenon, and is not necessarily related to immunity. An infant *in utero* may conceivably be sensitized, and is often prepared for sensitization by irritating body fluids from the mother. It can also be given a temporary immunity by the stimulating effect of body fluids from the same source. In the first case, however, the infant inherits the peculiar type of internal metabolism that can be irritated into sensitization, while in the second it receives a transferred acquirement which is only temporary and which depends on the chance of the mother's illnesses and their effect on her body fluids. Allergy, then, is internal and due to peculiarities in the individual endowment; infection and acquired immunity are foreign and fortuitous.

Inheritance

That heredity plays an important part in relation to allergy is shown by family histories and by the early age at which the symptoms become evident.

Case 1.—A baby of 8 months had curd dyspepsia with chronic diarrhoea, urticaria, and seborrhoeic eczema. The mother and the grandmother had had asthma, and there was also a history of eczema in the same branch of the family.

Case 2.—In another family the mother has eczema and a tendency to rashes with cineraria flowers. Of eight children one has hay fever, another urticaria, and a third asthma. The last baby has eczema, and was allergic to the mother's milk, and the penultimate child had eczema and developed asthma as the eczema disappeared.

Case 3.—In one family of ten children one had milk dyspepsia, two eczema, one croup, one asthma, and one serum sickness. Of the children of the last individual one had asthma, eczema, and urticaria, and the other angioneurotic oedema. One of the children of the asthmatic had asthma.

The following three histories show that in addition to inheriting a tendency to allergic manifestations a child may inherit a sensitive metabolism.

Case 4.—A baby aged 8 months had eczema, and had had acidosis three months before. There had been milk dyspepsia, and the child had decided digestive disturbances if given cod-liver oil or orange juice.

Case 5.—Another child, aged 7 years, had mucous colitis, urticaria, acidosis, and a tendency to catarrh and sneezing. Oatmeal, malt, and milk all very definitely upset her digestion, causing furred tongue and loss of appetite. Her father had asthma, her mother eczema, and her sister eczema.

Case 6.—In another family the father has eczema and asthma. Three older children have asthma. The penultimate baby had eczema, asthmatic wheezing, milk dyspepsia, and intolerance to cod-liver oil. The last baby was, I believe, saved from eczema because we kept the mother largely off milk fats during pregnancy, and also during lactation, which was successfully carried out for nine months.

Relation of Allergy to Metabolism and the Autonomic Nervous System

The above histories, which could easily be multiplied, show that individuals may inherit a metabolism that may become overloaded and insecure, and thus irritate another endowment—a sensitive autonomic nervous system.

The composition of body fluids is dependent upon efficient metabolism. Disturbed metabolism may give deficiencies or cause the presence of irritating bodies; hereditary tendencies may assist in producing such conditions. Hypochlorhydria, deficiencies of liver action,⁸ chronic maldigestion of fat with excess of fatty acids, abnormalities in water absorption and retention, and defects in protein metabolism may all occur. The breaking down of absorbed protein and its rebuilding into the special protein of the individual may be upset in allergic persons. Colloidoclasia occurs, and histamine is liberated, giving rise to allergic reactions, the skin and the mucous membranes being the areas in which histamine is most likely to be set free. The nervous tissues, especially the more sensitive ones, may be undernourished or irritated by abnormal body fluids: we have the examples of calcium deficiency and spasmophilia. Amino-acids and other toxic bodies circulating in tissue fluids can irritate nerve cells—including those of the autonomic nervous system. This system is closely related to the ebb and flow of tissue fluids, to changes of blood pressure, to secretory activity of glands—especially the endocrine—to contraction of tubes as found in asthma and peristalsis, to skin alterations such as flushing, paling, sweating, and oedema, and to expression of the emotions such as laughing, crying, elation, and depression.

I have previously said² that we ought to distinguish allergic disturbances from infections because they are chemical, metabolic, and internal rather than external and fortuitous. If we make this distinction, and if we realize the importance of the part played by the autonomic nervous system, we can understand the reasons for the following happenings, which so often puzzle our infection-educated minds.

Allergic symptoms come and go suddenly. Only an autonomic nervous system disturbance can explain the sudden appearance of a localized collection of fluid, as there is in angioneurotic oedema, or the sudden advent of spasm and distress, as in asthma. The disappearance of symptoms may be equally rapid. The remarkably quick action of some of the remedies used for the treatment of allergic symptoms can be explained by their effect on the autonomic nervous system. Allergic symptoms are interchangeable. Eczema may be relieved by the appearance of asthma, or vice versa, or asthma may be relieved by the appearance of another allergic symptom such as colitis.

Purely allergic symptoms are usually afebrile, in striking contrast to the high temperature reactions of infective illnesses. This comparative absence of temperature reactions indicates metabolic changes of a different nature from those produced in infections, and the greater part played by nervous influences in the production of allergy.

If an acute infection takes place metabolism is disturbed and allergic symptoms usually disappear temporarily; they may also disappear when a depletory condition such as diarrhoea arises. If a child is taken into a hospital or nursing home where physical and mental stress are lessened, and also the likelihood of unsuitable diet, the allergic symptoms tend to disappear because the autonomic nervous system is soothed and is not likely to be irritated by faulty products of metabolism.

When there has been constant repetition of allergic symptoms it is found that very little provocation, sometimes only psychical, is needed to produce the manifestations. This shows that there is a tendency to the development of a system habit, and one which undoubtedly can be referred to the autonomic nervous system and to metabolism.

Autophilic and Autopathic Individuals

These reasonings, showing as they do the internal and autonomic origin of allergic manifestations, have led me to suggest a new name³ for the individuals who inherit a tendency to allergic manifestation. I call them "autophils," because they have an insecure internal metabolism and a sensitive autonomic nervous system; if they have developed allergic symptoms I call them "autopaths." We have parallel words in spasmophil and hydrophil, and in neuropath and psychopath. Such words may not be strictly philological, but they are useful.

The following description of autophils is based on my experience limited to children and incidentally to their parents. Autophils are pallid but not necessarily anaemic; they flush and pale easily, and may have motion sickness. They faint on little provocation, such as the sight of blood. They have intense emotional reactions, and the mental stress so produced reacts on their physical well-being; after periods of stress and strain they show dark circles under the eyes. They are generally of the lean schizoid type, though this may not be evident in infancy. In metabolism they are katabolic rather than anabolic in that they tend to eat largely and to use up what they eat rather than to store it. Their appetites are good at first, but in adverse mental and physical conditions the tendency is to overload metabolism, thus producing furred tongue, loss of appetite, constipation, rough patches on the skin, and intermittent deposits of urates.

It is a striking point that in many of these cases milk, fats, rich vitamin preparations, cod-liver oil, bananas, and citrus fruits may not agree, and, if forced upon them, may help materially to overload the internal metabolism. Bracing climates and east winds may have a similar adverse effect. It is probable also that the overloading of metabolism produces a lowered resistance to infections and a proneness to catarrh and glandular enlargements. A vicious circle is thus caused, because catarrh once established in nasal, bronchial, or intestinal areas may encourage defective metabolism. Further, if sensitization to the special proteins produced by the bacteria has arisen, sensitization phenomena may follow any exacerbation of chronic infection.

Mentally, autophils are emotional, sensitive, excitable, and keenly interested. Mental stress may lead to irritability, moodiness, worrying, meticulousness, or other similar signs of nervous overstrain. They are inclined to be introspective and of the type of person who, in later life, develops neurasthenia.

Autopaths

Sensitization occurs either from the shock of one large dose or from a more prolonged provocation by small doses, and I wish to point out that overloading metabolism has a distinct contributory effect in the production

of sensitization. An autophil who has been overloaded by defective metabolism is likely to develop allergy, but one who has not been so overloaded will probably remain healthy. Once overloaded or sensitized, autophaths are liable to recurring attacks of seborrhoea, erythema, urticaria, angioneurotic oedema, eczema, ulcers in the mouth, milk dyspepsia in infancy, geographical tongue, bilious attacks, cyclical vomiting, colitis, spastic colon, croup in infancy, hay fever, asthma, migraine, convulsions, orthostatic albuminuria, haemoglobinuria, and arthritic signs.

Management of Autophaths

Autophaths to avoid becoming autophaths should always live within their limits of physical and mental endurance, and should avoid sensitization. Overloading of metabolism from faults of assimilation or from waste products may be brought about by faults in diet, injudicious exercise, too much excitement, and chronic sepsis.

Diet is chosen to avoid excess of foods which may irritate metabolism and prepare the way for sensitization allergens. Rich creams and oils when combined with other factors in diet seem to do this, and to cause fatty acids to circulate in the tissue fluids. Milk, and especially creamy milk, eggs, cod-liver oil, milk chocolate, and rich proprietary tonics are examples. If vitamin medication is indicated the concentrated drop preparations may be the best. There is some chemical property in sour fruits, and especially in citrus fruits and bananas, which irritates the metabolism of allergically inclined individuals, especially when in combination with the rich fatty foods. The ripening of fruit is very important, and may be incomplete or only finished after the fruit has been gathered and packed. Proteins and carbohydrates, especially sugar, usually suit, and fresh salads should be eaten if liked. Sensitization is a more particular phenomenon than general irritation and overloading of metabolism. Numerous foods may contain irritant allergens, including whey, egg (white), fish, fowl, and some meats. Removal of the allergens by the elimination diet plan of Rowe* is possible.

Elimination from the skin is also important. Autophaths tend to sweat, and a sweat is a wholesome relief to them. Controlled exercise is therefore good, but exercise taken immoderately or jarringly to the neuro-muscular co-ordination may produce waste products and overloading of metabolism, and irritate the autonomic nervous system. Autophaths are very likely to be driven to excessive or jarring exercise by their keen mental activity. On the other hand, the relief of orderly activity to a sensitive autonomic nervous system is great. One can understand the value of massage and of rhythm and music in exercises, bringing as they do relief of tension and added interest.

Excitement and emotional stress may disturb the metabolism of autophaths and upset an excitable autonomic nervous system. Disorders of blood pressure, pulse rate, and even acidosis may ensue. Erythema in conversation may indicate the strain that emotion puts on the autonomic nervous system of an autophil.

Toxins can interfere with metabolism or have adverse effects in nervous tissues. In autophaths there may be sensitization to bacterial allergens; local irritation may determine the site of the allergic manifestation.

Sensitization is brought about by overdose, sudden and massive, or repeated and fractional, of an irritative allergen. It is difficult to avoid because it usually appears without warning, but when family histories indicate that a child may be an autophil, and perhaps also indicate a likely sensitization allergen, preventive measures can be taken.

Treatment of Autophaths

An ordered control of metabolism and autonomic nervous system may prevent many autophaths from becoming autophaths, but an overloaded metabolism or an irritated autonomic nervous system may result in some of the symptoms of allergy enumerated above. Sensitization may be very decided and the offending allergen obvious and localized. Desensitization may then be successful, and the removal of that one allergen may effect a cure. In most cases, however, the problem is not so simple. An autophath is probably liable to further sensitization to other allergens if the metabolic condition which produced the first persists. Again, sensitizing allergens may not be readily picked out, nor be limited in number. Specific desensitization is consequently not always possible or effective.

Treatment consists, therefore, not only in attempts at desensitization but also in breaking any vicious circle of infection and lowered general health, in raising the general health and well-being, in improving metabolism and elimination from the bowels, kidney, and skin, in avoidance of mental and physical stress, and in careful control of diet.

Medical remedies are divided into four classes: (1) those directed to the relief of allergic symptoms, such as adrenaline, ephedrine, and anaesthesia; (2) those directed to improving metabolism and tone of nervous tissues by alteratives or tonics, change of air, or by removing chronic sepsis; (3) those directed to aiding metabolism by supplying deficiencies in digestive juices or aiding elimination; and (4) surgical measures for relief of spasm, including sympathectomy.

Summary

Allergy is a state of sensitization in which the system shows habit reactions to certain foreign metabolic irritants, usually protein in nature. These reactions are dermal, vascular, haemic, respiratory, digestive, renal, arthritic, cerebral, or cardiac, according to the individual and to the local irritation, whether traumatic or infective or chemical, the last being usually the production of histamine-like bodies. Allergy tends to develop in autophaths who have usually inherited an excitable autonomic nervous system and irritated an unstable metabolism. Autophaths may remain unsensitized, unirritated, and in good health, or may become sensitized and irritated into being autophaths.

J. C. Saunders (*Irish Journ. Med. Sci.*, September, 1934, p. 520) states that the average decennial mortality from diphtheria in the Irish Free State has increased from 4.7 per 100,000 in 1864-70 to 9.4 per 100,000 in 1921-30, whereas during the same period it has decreased from 78 to 3 per 100,000 in Denmark and from 11.4 to 2.9 per 10,000 at ages under 15 in England and Wales. A steady increase in mortality has taken place in the urban areas of Dublin, Cork, and Limerick, as compared with a corresponding decrease in the urban areas of Belfast, Birmingham, and Ipswich. The causes for the relatively high diphtheria mortality in the Irish Free State appear to be inadequate dosage of antitoxin, delay in its administration, and inadequate arrangements for its distribution to practitioners. It is probable that a vigorous scheme for diphtheria immunization would reduce the mortality as it has done in New York.

DIVERTICULITIS WITH UNUSUAL COMPLICATIONS

REPORT OF TWO CASES

BY

HUMPHREY FOXELL, M.B., B.S.LOND.

In most textbooks the subject of diverticulitis is dismissed in a few lines, but practitioners have had experience of difficult cases which have turned out to be diverticulitis, with some complication or another. These two cases illustrate such difficulties.

Case Record No. 1

The first case was that of a man of 54 who gave the following history. His health usually was good, but some years ago he had a duodenal ulcer for which a short-circuit operation had been performed. This operation had been a complete success, and the only symptom which reminded him of his former trouble was occasional "acidity." When this condition arose he had been advised by a consulting physician to take at any such time 60 grains of sodium bicarbonate. He stated that this always gave him immediate relief. It had been his custom for some years to keep a supply of 5-grain tablets, and when he required a dose he would take twelve of these, as he found this the easiest way of measuring 60 grains. These tablets he purchased himself. Although he had a tendency to constipation he never allowed this to get the upper hand, as he was in the habit of taking purges; this point is rather important from the subsequent history.

On the morning of February 26th I was called in to see him owing to his being extremely sleepy, from which condition he could be roused with great difficulty for a few minutes only, during which time he remained drowsy and was never fully awake. The preceding day had been very cold, with a heavy fall of snow, and he had had a good deal of indigestion. He had noticed on former occasions that snow always made him "livery." As he was going out to dinner that evening he took his usual dose of sodium bicarbonate just before leaving home. He then drove himself and his wife about a mile to the dinner party. Before dinner he took a cocktail, but only drank half; normally he was an abstemious man. The house was very hot and the dinner started with some hot soup. After he finished it he pushed his plate away, folded his arms on the table, laid his head on them, and went fast asleep. He was roused with great difficulty, and he walked into another room, where he said he felt very funny. He then managed to make himself vomit, after which he felt better, but very sleepy. He was left in this room, where he slept soundly for about three hours. After having been woken up he was able to drive his car home without much difficulty, but could not drive into his garage. Before going to bed he took another twelve tablets of sodium bicarbonate.

Next morning when I saw him he was, as already stated, in an exceptionally sleepy condition. His pulse rate was 56 and of rather poor character. On the left side of the abdomen, about the middle of the descending colon, there was a lump as large as a big fist which gave the impression of being possibly a faecal mass. Rectal examination was negative; urine normal.

I gave him hypodermically 1 c.cm. of pituitrin and 0.5 c.cm. of 1 in 1,000 adrenaline, and after a short time he seemed to become a little less drowsy. The relatives expected, and demanded, a diagnosis. I therefore told them that I had found a condition of partial intestinal obstruction which must have been going on for a long time, and this allowed a slow absorption of waste products to take place, so producing a condition of poisoning by auto-intoxication. In other words he was suffering from sapraemia.

Later in the day a simple enema was given following an injection of 6 oz. of olive oil, with the result that an

enormous stool was produced, in spite of the regularity of the taking of purges. During the rest of the day he gradually got better and by the evening was almost normal, except for a slightly drowsy state.

On February 27th—that is, two days after the onset of the sleepiness—he had a return of "acidity" and took another 60 grains of sodium bicarbonate about 6 p.m. At 7 p.m. he was extremely drowsy and had to be helped to bed. He slept soundly for about fourteen hours, when he was roused and was able to keep awake. He was given another enema, with a very large result, but still felt sleepy during the day.

On the fourth day he felt quite well again, and was so definite that he felt much better that on the sixth day he went back to his office and spent the usual day. An x-ray examination was carried out following the administration of a barium enema, and this revealed a condition of diverticulitis affecting mainly the descending colon, which also showed a very marked spasm. Thus the diagnosis of diverticulitis was confirmed. On the strength of this he was advised a daily bowel irrigation, and this was carried out.

We were now all congratulating ourselves on a satisfactory diagnosis and felt we were dealing with a more or less straightforward case, but on the same evening—that is, the sixth day—he came home from his office owing to a return of indigestion and took yet another 60 grains of sodium bicarbonate. The following day I was called in to see him and found him just as drowsy as he had been before, and I called in a consulting physician, who could throw very little light on the case. A lumbar puncture was performed. The intraspinal pressure was normal and the fluid itself was found to be normal to every test. We were then not very much further on, except that once again the patient recovered.

About midnight of the ninth day I received an urgent summons and I found the patient definitely cyanosed with Cheyne-Stokes breathing and a feeble pulse of only 48. An injection of pituitrin and adrenaline seemed to improve his condition somewhat. The following morning he was again seen by the consulting physician, who was still baffled by the condition. Ophthalmoscopic examination showed some anaemia of the retinal vessels suggesting cerebral anaemia.

Yet another attack occurred on the fourteenth day: and, talking over the case with his wife, who was naturally terribly anxious, it suddenly struck me that there was a definite connexion between the attacks of drowsiness and the taking of the sodium bicarbonate. I therefore asked her to let me have the bottle of tablets, and on tasting one, it was at once obvious that it was not sodium bicarbonate, but on throwing the remains of the tablet in the fire there was a yellow sodium-flame produced. I immediately took the tablets to be analysed, and the result was reported to me as medinal. This is also known as sodium bibarbiturate.

The remarkable part of this case is that in a space of a fortnight this man had taken six doses of 60 grains of medinal.

Case Record No. 2

The second case was that of a man of 65 who was normally in robust health, a stocky type but inclined to be fat. He was a great worker, being the head of a very large concern in which he took a personal interest. He always suffered from a moderate degree of constipation, but kept his bowels working with a daily dose of salts first thing in the morning. It was also his habit to take Vichy water almost daily. He was inclined to be irregular with his meals, as he felt they were a waste of time and interfered with his work.

I was first called in to see him for this present illness on August 11th because he was not feeling well and had had "difficulty with his bowels and pain in his stomach." Examination of the abdomen revealed a large mass on the left side, reaching downwards for about 6 in. from the lower border of the ribs. The consistency of this mass suggested a collection of faeces. It was fairly tender on light pressure, but quite painful when pressed hard. A consulting physician saw him on this day.

The treatment employed was liquid paraffin by the mouth, non-residue diet, mainly fluid, and enemata. This latter produced soft and watery results, with several hard, stale, dark lumps, very few being any larger than walnuts. His progress appeared to be quite satisfactory, and although the lump was still palpable, it was considerably smaller.

As in the first case, everybody concerned was quite pleased with his condition, and we thought we were out of the wood. On the sixth day, however, I received an urgent call about 10 p.m. owing to a sudden attack of very severe pain, on the left side. He was then partially collapsed, cyanosed, and sweating; his pulse was poor. He stated that he had never endured such "terrible" pain before in his life. The tenderness over the lump was very marked, and he could hardly stand the lightest pressure.

A consulting surgeon was called in the same evening, and he considered that there was a possibility of a bowel perforation. He expressed a wish to have the opinion of another surgeon, and when the latter arrived later in the evening, they both considered that, at any rate, that evening the patient was in too bad a state to have his abdomen opened. Here it should be stated that he was a difficult subject to examine, owing to his build and to the extreme tenderness of the lump. Morphine was given hypodermically, and after a short time the condition became much better. Next morning—that is, the seventh day—he was fit enough to be removed to a nursing home, to be kept under observation.

Owing to the improved general condition it was considered possible to perform a laparotomy, should this be deemed necessary. One surgeon was inclined to take the risk, but the other thought the risk was too great, and, strange as it may seem, the consulting physician was rather in favour of the operation. A third surgeon was consulted, and it was decided to give the patient a barium enema and to take an x-ray by means of a portable apparatus. The x-ray revealed the presence, as in the former case, of several small diverticula, with a marked spasm of the descending colon.

A super-consultation was then held, at which were present three consulting surgeons, a consulting physician, the radiologist, and the G.P.! The result of this was that everybody agreed that if there was a real obstruction, then the only operation possible was one to relieve the obstruction by an opening into the bowel above this area. This would mean a colostomy of the transverse colon, and we came to the unanimous conclusion that this would be exposing the patient to too great a risk. Furthermore, the patient's condition was better, and there was now very little pain or tenderness, though the bowels were failing to function.

At this moment in the consultation a very dramatic interruption occurred. There was a tap at the door and the sister of the nursing home came in with a specimen glass full of a fluid that looked like blood. It actually was almost pure blood, and in fact was haematuria. The case was now more obscure, but one of the experts took a very serious view and expressed the opinion that the haematuria must be of toxic origin and that therefore the outlook was very grave; nevertheless, we still stood by our opinion that no operation was possible. The problem, however, was completely cleared up next day.

When I saw the patient next morning he seemed very much better. He had got rid of the barium and with it he had passed a good deal of faecal matter, but, more than this, he made a very important statement—namely, that when passing water that morning he had heard a little "tinkle." To cut a long story short, he had passed a small stone. Suddenly the case became clear. The severe attack of pain in the left side which occurred on the evening of the sixth day was actually an attack of renal colic due to the passing of a small stone down the ureter. The lifting about of the patient for the taking of the x-rays had been enough most probably to move the stone on over the brim of the pelvis into the bladder. This caused the haemorrhage which the patient got rid of a little later. The passing of the stone per urethram the following day completed the picture.

AURAL VERTIGO*

BY

W. S. THACKER NEVILLE, M.D.DUB., F.R.C.S.ED.

HARROGATE

We recognize our position in space by means of the muscle senses in the soles of the feet, by our eyes, and by our semicircular canals. Labyrinthine vertigo consists in a false sense of movement of the patient or of his surroundings. The movement may be in a linear, rotary, or vertical direction, and is accompanied by nausea, vomiting, pallor, sweating, and sometimes diarrhoea. Sensations of forward and backward movements are not seen, but if present are in favour of a neurasthenic or cerebral vascular condition. Besides this false sense of movement the patient may really fall, or may be flung out of his chair, or have a sensation of being pushed, yet he never loses consciousness. The onset of these sensations is sudden; they last only a short time, and are followed by a feeling of unsteadiness on the legs.

The function of the labyrinth may be interfered with if there is a lesion in the vestibular tracts in the cerebellum or in the vestibular nerve, or if these nerve endings are affected by a toxin, or the blood supply of the semicircular canals is suddenly increased or decreased, or the fluid in those canals is exposed to pressure or toxins.

Lesions in Vestibular Tracts and Vestibular Nerve

The commonest cause of a lesion which affects the vestibular nerve tracts in the cerebellum is thrombosis of the inferior cerebellar artery, in which there is a sudden onset of vertigo and nystagmus to the affected side associated with ocular sympathetic paralysis and paresis of the soft palate and vocal cord and disturbances of sensation. A vascular lesion in the lateral part of the pons may also, according to Brain, produce vertigo, deafness, and tinnitus associated with paralysis of the seventh and eighth nerves and disturbances of sensation.

The vestibular nerve tracts may also be affected, in disseminated sclerosis, in which there is vertigo without loss of hearing. The vertigo is usually accompanied by an intention tremor, absence of abdominal reflexes, and extensor plantar responses with possibly optic atrophy. The nerve tracts may also be disorganized by a head injury. In such cases there is tinnitus and vertigo; the vertigo usually tends to become less, though in some cases it, like the tinnitus, persists for a very long time. Vertigo may be the aura of an onset of *petit mal*, but it can easily be differentiated from aural vertigo, since in the latter there is never loss of consciousness. Vertigo may also occur in neurotic individuals; it consists in a feeling of the legs giving way, and is accompanied by intense anxiety and palpitation which may, according to Russell Brain, be due to a fear of heart disease.

The commonest lesion of the vestibular nerve itself is a tumour of the eighth nerve. The patient complains of vertigo, tinnitus, and deafness, and the striking feature is that there is anaesthesia of the cheek and later fascial nerve paralysis. (Anaesthesia of the cheek may be preceded by anaesthesia of the cornea.) Examination of the labyrinth shows a complete loss of function with, according to Eagleton, a loss of function of the vertical canal on the opposite side.

The Semicircular Canals in Causation of Vertigo

In an aurist's experience the semicircular canals themselves are the commonest cause of vertigo. These canals are surrounded by a network of blood vessels, and contain

* Read before the Yorkshire Branch of the British Medical Association, September, 1934.

fluid and nerve endings. On the peripheral aspect of the canals is the middle ear, which communicates with the canals via the oval and round windows.

Just as we can get changes in the walls of the blood vessels of the eyes, so we believe we can get similar arteriosclerotic changes with or without haemorrhages in the blood vessels of the labyrinth, which would account for the vertigo that occurs in elderly people on stooping or turning their heads. These blood vessels may undergo spasm with loss of hearing, then relaxation followed by tinnitus, giddiness, and return of hearing, and it is a question whether such cases could not be cured by stripping the sympathetic nerves of the internal carotid artery, or by removing the superior sympathetic ganglion. Russell Brain considers that spasm of these arteries also accounts for the vertigo that occurs in sufferers from migraine.

The fluid in the canal can produce vertigo when it is moved, as when one performs the rotation or caloric tests, or is on a ship. It is said that to avoid sea-sickness it is best to lie flat on the back. This fluid may also be affected by toxins; thus in acute otitis media there may be vertigo and nystagmus to the affected ear due to absorption of toxin stimulating the nerve endings, or, if the infection is more severe, destruction of the nerve endings and consequently a nystagmus to the opposite side. In the case of the nystagmus to the same side, suction applied to the Eustachian tube or a paracentesis of the tympanic membrane will allow the toxic fluid to escape, or in severer cases a mastoid operation will be necessary. When there is nystagmus to the opposite side a serous or suppurative labyrinthitis must be diagnosed. As long as any hearing is present we diagnose serous labyrinthitis and do not operate, but when all hearing has gone and the hot caloric test is incapable of affecting the nystagmus we are forced to diagnose the suppurative condition. If the suppurative labyrinthitis is secondary to an otitis media I do not operate unless the signs of labyrinthitis increase instead of decrease, or unless meningitis appears, but if it follows an operation such as the removal of a polypus or a mastoid, I then perform a labyrinthectomy at once.

Besides reaching the semicircular canals directly from the middle ear as just described, toxins may reach the canals via the blood stream, as in the case of those from the intestine or from alcohol, tobacco, or a septic focus; thus one patient drove his car from side to side of the street, but when his tonsils were removed his vertigo disappeared.

Displacement of the Stapes

Another cause of vertigo is displacement of the stapes, which may be due to an oversecretion of fluid in the semicircular canals. This is considered by Mygind and Dederding to be the commonest cause of the kind of aural vertigo which is usually termed Ménière's disease. This water-logging of the labyrinth occurs in those who have faulty water metabolism; such patients are usually easily recognized, as they show a loss of low notes and absence of or decreased bone conduction, deafness which varies from day to day, an increase in weight, and a thickening of the subcutaneous tissues. However, I would not diagnose a patient as water-logged without giving 1,000 c.cm. of fluid, and seeing how much fluid the patient had passed, and how much he or she had increased in weight after an interval of four hours. The increase in weight equals the weight of the retained fluid, and thus, by weighing the patient before the fluid is taken and at the end of four hours, the amount of fluid retained is estimated. Such patients are cured by dehydration with salyrgan, a no-salt diet, and extreme limitation of fluid.

An attack of aural vertigo in which the patient has nystagmus and vomiting may be arrested by an injection of bulbocapnine. This drug, orally administered, is also useful in some cases to ward off attacks.

Another cause of displacement of the stapes is blockage of the Eustachian tube, with consequent absorption of air in the middle ear. This occurs in inflammatory states of the Eustachian tube or in swelling of the mucous membrane due to water-logging. Such patients are cured by reducing the swelling in the Eustachian tube and by catheterization. To reduce the swelling in the Eustachian tube a nasal operation may be necessary.

At times no cause can be discovered to account for the presence of aural vertigo, and in those cases the best treatment is Mollison's—that is, destruction of the nerve endings by injecting alcohol into an opening made in one of the semicircular canals. This I have done on three occasions. Before adopting this treatment I used to destroy the cochlea and semicircular canals by a labyrinthectomy. The injection of alcohol, however, is easier, and exposes the patient to less trauma. Brain specialists such as Dandy, Cairns, and Dott cure this form of vertigo by dividing the seventh nerve, and lately Dandy has been successful in dividing the vestibular branch alone, and so retaining the remnant of hearing that is often present in these patients.

TONSILLECTOMY WITH LOCAL ANAESTHESIA

A REVIEW BASED ON 500 CASES

BY

GEOFFREY MOREY, M.B., B.S. ADELAIDE, D.L.O.

JUNIOR SURGEON, EYE AND EAR HOSPITAL, SHREWSBURY

For some reason unknown to me local tonsillectomy has never received very favourable consideration in England; yet the mere fact that this is almost the only method employed in many of the large Continental clinics should be sufficient evidence that it is definitely worthy of greater consideration than it has hitherto received. Having just completed a series of five hundred cases in patients whose ages ranged from 16 to 74, I feel that a short description of the technique may not be out of place, since many advantages are claimed over the more universal dissection under general anaesthesia. The advantages of using a local anaesthetic are that the operation is considerably more speedy without there being any sacrifice of efficiency; that there is a minimum amount of bleeding (often there is literally none at all); that there is no vomiting; and that there is a cleaner dissection. The patient suffers no pain and extremely little discomfort.

Technique

The nurse sprays the patient's throat several times with 10 per cent. cocaine and adrenaline, and then the injection, which is the most important part of the operation, is commenced. It should be stressed that the quantity of novocain solution injected is even more important than its strength. About 30 to 40 c.cm. of a 1/2 per cent. solution is recommended.

With a long needle, the point of which is curved almost to a right angle, the novocain is injected from a 20 c.cm. syringe. Five injections, each of approximately 3 c.cm., are made into each tonsil, the anterior portion of the capsule receiving three and the posterior portion two. The needle is inserted just under the mucous membrane, which is immediately thrown out into a bleb as soon as the novocain reaches the tissues. It should be inserted first near the uvula, with the point turned outwards and downwards, a few millimetres from the free border of the pillar; then midway between the upper and lower pole, with the point directly downwards; and finally into the lower pole near the base of the tongue, with the point directly downwards. The remaining two injections are made behind the posterior pillar in the upper and lower poles respectively. Here, however, the needle point should enter the tissues horizontally, and the shaft of the needle be drawn well over into the opposite angle of the mouth. After the injection the pillars are, of course, very swollen and oedematous, and the patient should be left for ten minutes for absorption to take place. This wait is important, for during this time the capsule becomes so well infiltrated that the actual dissection of both tonsils may be completed with ease in less than three minutes.

The patient is now led into the theatre and placed in an ordinary chair. The surgeon sits facing him, and for convenience the patient is made to place a hand on each of his (the surgeon's) knees. A nurse standing behind the patient's chair holds the head in the required position and wipes away from the mouth any blood-stained saliva, after occasional spitting. No gag is necessary; nor, after the vulsellum has first gripped the tonsil, is a tongue depressor required. Beyond a sharp dissector, to incise the pillars, and a blunt dissector with a serrated edge, to free the tonsil from its now plainly marked capsule, no other instrument is required, except possibly a snare for the lingual prolongation. After the first tonsil has been removed it is a good plan to pack a small, loose piece of gauze into the fossa before proceeding.

If there are two or more patients for tonsillectomy it is a great saving of time to complete all the injections first, since the best effect from the novocain may be obtained if left for a minimum of ten minutes and a maximum of forty minutes. In this way two or three cases may be completed in considerably less than half the time taken by general anaesthesia. As there is little or no bleeding, an assistant is quite unnecessary. A powerful headlight is, of course, an essential.

Conclusion

Invariably the patient volunteers the statement that the operation has not been as painful as a tooth extraction, while all will admit, on being questioned, that "it didn't hurt a bit." It would seem from the patient's point of view that the apprehension is the worst part of the whole operation. This may be considerably allayed by a preliminary injection of morphine, and also during the operation itself by what the Viennese call "vocal anaesthesia." There is no doubt that a patter of conversation, however irrelevant, helps to quiet the patient. After the operation has been completed the patient walks back to his bed, and is able to return home within three or four days.

In this series of cases, which comprises every tonsillectomy that has recently come under my care—that is, unselected—I have had only one case where I was embarrassed by bleeding, and that finally required a general anaesthetic. There were three cases in the series that bled after getting back to bed, requiring the use of the clamp, but these were due to an incomplete dissection. No vessel has had to be tied. From the injection of novocain I have seen no harmful effects.

Clinical Memoranda

NON-TROPICAL SOLITARY ABSCESS OF LIVER

The subject of solitary abscess in the liver is usually associated in the mind with a tropical disease. It is of interest, therefore, to review a case where no possibility of a tropical origin could be admitted. Cabot,¹ discussing liver abscess, states that as a rule the diagnosis is made on the aetiology rather than on physical signs. Where there is no obvious cause such as amoebic dysentery or appendicitis the diagnosis becomes increasingly difficult. However, as Horder² has pointed out, such cases are often due to *Staphylococcus aureus* and are characterized by a latent interval between the original staphylococcal infection and the development of a liver abscess.

CASE RECORD

A. L., 20 years of age and single, had been in good health and following her occupation as a weaver until July, 1933. She then began to complain of slight intermittent pain in the right side of her chest which was at first regarded as pleurodynia. However, the pain became constant, more severe, and localized to the region of the eighth rib interspace in the right mid-axillary line. To digress for a moment, it is to be noted that later the liver was found adhering to the parietes at the place where she located the pain. Slowly her health deteriorated, anorexia, loss of weight, and night sweats being added to her original symptoms. After five weeks she took to bed, and one week later (September 7th) she was admitted to the Blackburn Royal Infirmary.

On admission, she appeared thin and anaemic. Her temperature was raised and there was obvious toxæmia. Her heart and lungs were healthy, and the chest moved normally on respiration. There was, however, a suggestion of bulging of the lower part of the right side of the chest, which must have been due to enlargement of the liver. The lower margin of the liver could not be palpated as there was considerable muscular rigidity in the right hypochondrium. The abdomen was thin and the spleen was not palpable. A search for tenderness was not very satisfactory as the patient could not distinguish between pain and tenderness. The kidneys were not palpably enlarged nor was tenderness elicited during palpation. A provisional diagnosis of perinephritic abscess was made, leading to a thorough investigation of her kidneys. An x-ray photograph of the urinary tract was negative. Her urine on examination revealed no abnormalities. Normal pyelograms were obtained from both sides, so it was decided to look to the liver as the probable cause of her illness. The chest was examined with the x-ray screen but the diaphragm was seen to move normally with respiration and did not present any abnormal bulging or fixation.

On September 8th her blood was examined. The red blood cells were estimated at 4,400,000 per c.mm., haemoglobin 65 per cent. The white blood cells showed a leucocytosis of 20,000 per c.mm. with 80 per cent. of neutrophils in the differential count.

Whilst these investigations were in progress her temperature rose every evening to 102° F. and fell in the morning to 99°, and she was obviously losing ground every day. Liver abscess was suspected, and on September 10th the liver was explored with a Barker's lumbar puncture needle under a general anaesthetic. Introduced in the mid-axillary line and passed upwards and backwards, as is usually recommended, no pus was found, but, on directing the needle downwards and inwards towards the abdomen, thick pus was easily obtained. The abdomen was then opened by an incision just below the right costal margin. The liver was not enlarged downwards, but omentum and bowel were firmly adherent along its lower margin. Working up on the right side between the diaphragm and the lateral surface of the liver, an area of adhesions was encountered about three inches from the lower margin of the liver. On breaking this down the finger slipped easily into a large unilocular abscess cavity in the right lobe of the liver.

¹ Cabot: *Physical Diagnosis*, eighth edition, p. 380.

² Horder: *Medical Notes*, p. 73.

The pus was evacuated and a tube passed into the abscess cavity through the abdominal incision. From that time she progressed in uneventful fashion.

At the time of writing (July 6th, 1934) she is in good health and married. The pus was examined and a pure culture of *Staphylococcus aureus* grown from it. Her history was gone into again and apparently she had had a carbuncle on her right forearm some months prior to the present illness. If this was the portal of infection a well-marked latent period occurred in this case prior to the onset of symptoms of liver abscess.

I am indebted to Dr. J. J. O'Connor of Oswaldtwistle for so kindly supplying me with details of the after-progress of this case.

RECOVERY OF SIGHT FOLLOWING SEVERE CORROSIVE BURN OF CORNEA

The case recorded below illustrates the value of early and intensive treatment in securing recovery from what may at the first instance appear to be beyond hope.

On January 28th, 1934, a workman had to remove a large cock from a chemical plant because of the tap having seized. He had this object fixed in a vice, and tried to loosen the part by the flame of a blow-lamp. He did this on his own part, and contrary to regulations, and, further, he was not wearing protective goggles.

During operations an explosion occurred, and hot fluid contents splashed all over his face and into both eyes. He at once applied water to his eyes, and was rushed to the adjacent first-aid station. The fluid on the cheeks and in the eyelids was found to be strongly acid. The conjunctivae were intensely swollen, and the cornea completely opaque and white. Immediate treatment to the eyes consisted of inducing a gentle, continuous flow of a 1 per cent. alkaline solution of sodium carbonate at 98° F. for about ninety minutes. As a relief from pain morphine 1/4 grain was given hypodermically. The facial burns were treated by alkali and then covered with a tannic acid jelly, lint, etc., to maintain asepsis and protect from air changes.

The man was fairly free from shock, and was sent by ambulance to Manchester Royal Eye Hospital, where he was at once placed under treatment. The eyes were washed out every half-hour for over twelve hours with a weak alkaline fluid, atropine was instilled, and after this time washing was reduced to once per hour for a further day—after that at longer intervals. For about two weeks no hope was given for even partial recovery of sight, but soon after the corneae began to clear up, and then favourable progress was rapid, the prevention of conjunctival adhesions having been achieved. In about four weeks' time the corneae were almost normal, the man's vision being, of course, unaided by accommodation owing to the daily instillation of atropine. The scars on the face were not very important, but cicatricial contractions formed on and above one upper eyelid. These luckily did not interfere with the action of the eyelid.

The man was discharged from hospital roughly six weeks from the date of the accident, and attended three times a week for another fortnight. Atropine was then discontinued, and some sixteen days later he resumed work, with practically normal vision and no corneal opacities.

It is quite evident from this gratifying result that very persistent washing with suitable fluids is called for in these cases, and, for the man's part, he should be glad the corrosive was not of alkaline type.

I am writing this to mark my appreciation of the very strenuous and successful methods used by our Royal Eye Hospital.

Medical Officer, British Dyestuffs Corporation,
Blackley, Manchester.

Reviews

REGIONAL ANATOMY

The *Synopsis of Regional Anatomy*,¹ by Professor T. B. JOHNSTON, is a book which has been written with the object of providing the student with a short summary of the main facts, and is intended to be used by the reader with the bones and dissected preparations before him. It is assumed that the student has already acquired a working knowledge of anatomy, and merely needs a guide for the revision of his previous knowledge, as, for instance, when preparing for the final examinations of the medical curriculum. The author does not attempt to include the finer details of anatomy required for the award of honours or examinations for the higher diplomas, nor does he allude to recently published work on special subjects. The book is a plain, straightforward statement of the essential facts of anatomy written for the benefit of the average student, who has insufficient time to read through larger volumes, which often comprise about 1,500 closely printed pages. The value and interest of the book is very considerably enhanced by short references to the practical application of the facts recorded, and also the employment of italic type to emphasize the more important points.

A special feature of this third edition of the *Synopsis* is the use of the revised terminology which has recently been approved and adopted by the Anatomical Society of Great Britain and Ireland. The reader will readily appreciate the value of this alteration, as he will at once realize that the change is in the direction of simplification. A great deal of time and thought has been expended on this task of revision, which has provided an eminently satisfactory solution of the vexed question of old *versus* new terminology; and Professor Johnston, who has been one of the chief workers appointed to serve on the Revision Committee, is to be congratulated on the well-merited success which has crowned this advance in descriptive nomenclature.

Within the limits of the author's intention the book is admirably suited for the student's requirements, and is remarkably free from errors, any defects being rather those of omission than commission, and we can confidently recommend it as a reliable epitome of an extensive and detailed subject.

QUINSY

A further volume of the Collection of "Médecine et Chirurgie Pratiques," published by the firm of Masson, is *Les Phlegmons de la Loge Amygdalienne*,² by G. CANUYT and P. PAULL. It might be supposed that little fresh could be produced by the study of such a hackneyed subject as quinsy, but Professor Canuyt has raised several points which deserve notice. His anatomical notions on the relation of the tonsil to the muscular wall of the pharynx will not receive general support and are not in accord with recent anatomical observations, but he has gone to much trouble to prove by experiment and by clinical and post-mortem observations that the pus in a quinsy collects between the tonsil and the lateral wall of the pharynx. It has been suggested that the pus may occupy a deeper plane, but it would not have occurred to many that such elaborate proof of a self-evident proposition in pathological anatomy was necessary.

¹ *A Synopsis of Regional Anatomy*. By T. B. Johnston, M.B., Ch.B. Third edition. London: J. and A. Churchill, Ltd. 1934. (Pp. 469; 11 figures. 12s. 6d.)

² *Les Phlegmons de la Loge Amygdalienne*. By Prof. G. Canuyt and Dr. P. Paull. Paris: Masson et Cie. 1934. (Pp. 128; 33 figures. 16 fr.)

Professor Canuyt is a strong advocate of the use of the exploring needle and syringe to prove the presence of pus here, just as it is used in other regions, a suggestion which may certainly be of value. In the treatment of quinsy the classical method described by Chiari of opening it by an incision in the middle of a line uniting the last molar with the base of the uvula is considered inadequate. Of the more radical methods the authors prefer to open the tonsillar fossa behind the anterior pillar and evacuate the pus without removing the tonsil. The cavity between the tonsil and the lateral pharyngeal wall is packed and the removal of the tonsil completed a few days later, but no special reason is given for not completing the operation of tonsillectomy in one stage, as recommended now by many laryngologists. Thus a rather unsatisfying compromise is reached between a primary tonsillectomy giving very free drainage, and the more conventional method of simple incision or drainage through the supratonsillar fossa followed after an interval for healing by tonsillectomy, if the patient is willing to undergo further treatment. Furthermore, the damage inflicted on the anterior faucial pillar by the technique advocated will not receive general approval.

The authors are certainly able to show that the classical method has unsatisfactory features, and the increasing adoption of the method of primary tonsillectomy supports their contentions. They have done service by calling attention to the pathology and treatment of a condition which is frequently and wrongly dismissed as trivial, but unfortunately have spoiled a book well worth reading by an astonishing amount of most tedious repetition.

ESSAYS ON PULMONARY TUBERCULOSIS

Dr. F. M. POTTENGER'S *Tuberculosis in the Child and the Adult*³ is rather a difficult book to label. Although it covers nearly the whole range of pulmonary tuberculosis it is not a textbook on the subject, nor is it a book of reference. It is perhaps best described as a coherent sequence of essays on almost every aspect of the problem, some contemplative and suggestive, others didactic and severely technical. This method of compilation gives the work quite a different balance from that of most books on the disease. Dr. Pottenger has been a well-known publicist for several years on certain phases of pulmonary tuberculosis; he is also the sponsor of some quite original views, and it would seem that he has used this book to collect the essence of his original work and to correlate it with the general principles of the diagnosis and treatment of pulmonary tuberculosis. Those who are familiar with his writings will find, as they expect, that the subject of the visceral neurology of pulmonary tuberculosis and its bearing on symptoms, physical signs, and diagnosis is treated very fully.

It is arresting to find, in these days of the ascendancy of the x ray, such strong advocacy of the value and practice of percussion and palpation. The reader may well quail at the task of acquiring such a delicate tactile sense as the author suggests he should; but since, if he hopes to be a good physician, he can never be too skilful in his methods of examination, he will find in this book fresh instructions on what is rapidly becoming a forgotten art. It must be borne in mind, too, that Dr. Pottenger does not ignore or undervalue the x ray, but his experience teaches him that, even with the help of the film, painstaking attention to minute physical examination is still well worth while. Elsewhere the book expresses broad views, the results of the author's very

wide experience, with an occasional rapid descent to the details of everyday practicalities, and finishes with some interesting specimen case histories illustrated with the usual unconvincing x-ray reproductions. (This unconvincingness is not the fault of author or publisher, but seems to be a vice inherent in all reduced x-ray reproductions.)

In such a work the carping reviewer could find many statements to criticize and opinions with which he strongly disagreed. But the opinions of an experienced man, whether agreeable or not, are always worth attention, and these this book provides, so the reviewer can safely leave the reader to agree or disagree with them for himself, knowing that in either event the reading of them will stimulate thought and be found worth while.

A CYCLOPAEDIA OF MEDICINE

With the eighth, ninth, tenth, and eleventh volumes of the giant undertaking known as *The Cyclopaedia of Medicine*,⁴ and edited by Dr. G. M. PIERSON, the subject-matter is carried a big step further, ranging from "Larynx, disorders of," to "Tartar and Tartrates" (omitting cross references not dealt with in the pages here reviewed). Random sampling of the four latest members of this series has revealed an excellent article on basal metabolism, by Dr. W. M. Boothby of the Mayo Clinic; a very practical account of ophthalmology as an aid to neurological diagnosis, by Edward Hartmann of Paris; and several well-illustrated sections on different aspects of radiology in vol. x. Similar experimentation with the index of vol. ix brought to light a section on acute lobar pneumonia of over seventy pages (double columns), based apparently upon 255 references, and the result is a bewildering collection of facts and observations which seems out of place in a work of this kind. This remark assumes that the whole production is mainly intended for the general practitioner out of touch with a good library, for the specialist is unlikely to require multiple monographs whose contents are often out of date as soon as publication has taken place. There is one more volume to come and an elaborate desk index. The British contributors to vol. xi include Professor John Fraser of Edinburgh, Professor L. S. P. Davidson of Aberdeen, and Dr. Alfred Pincey.

APPLIED CHEMISTRY

The current edition of *Thorpe's Dictionary of Applied Chemistry*, which began thirteen years ago and was completed seven years ago, is now being brought up to date by the publication of a two-volume supplement, of which the first volume is under review.⁵ The editors, Professors J. F. THORPE and M. A. WHITELEY, point out that probably greater progress in chemistry has been made during the last decade than during any corresponding period in the past, and hence an urgent need has arisen for including an account of these important advances in their dictionary. Instead of producing a new edition, it was decided to prepare a supplement dealing with selected subjects in which the greatest and most striking advances had been made. The subjects chosen are dealt with in short monographs by workers who are eminent in the field with which they deal. More than one hundred persons have contributed to this volume, and the list of

⁴ *The Cyclopaedia of Medicine*. Vols. viii, ix, x, and xi. Editor-in-Chief: G. M. Pierson, B.S., M.D. Ample illustrated with cuts and full-page black-and-white and colour plates. Philadelphia: F. A. Davis Co. 1934. (120 dollars.)

⁵ *Thorpe's Dictionary of Applied Chemistry*. Supplement, vol. i, A to M. By Jocelyn Field Thorpe, C.B.E., D.Sc., F.R.S., F.I.C., and M. A. Whiteley, O.B.E., D.Sc., F.I.C. London: Longmans, Green and Co., Ltd. 1934. (Pp. 680; illustrated. 60s. net.)

³ *Tuberculosis in the Child and the Adult*. By Francis Marion Pottenger, A.M., M.D., LL.D., F.A.C.P. London: Henry Kimpton. 1934. (Pp. 611; 88 figures. 36s. net.)

contributors includes most of the names best known in British chemistry. Each monograph gives a short review of important recent work in its subject, and also a few selected references.

The articles are arranged in alphabetical order, and the first volume covers the first half of the alphabet. The dictionary embraces the whole of chemistry, but it is interesting to note that a large proportion of this volume is devoted to subjects of biochemical or pharmacological interest. For example, there are relatively long articles on carbohydrates, enzymes, fermentation, and feeding materials, and on organic arsenicals, cinchona alkaloids, and digitalis. The prominence of such subjects is interesting evidence of the remarkable advances that have been made in organic chemistry and biochemistry during the last decade. This supplement will be found of great value by all who want a means of quick reference to new work in chemistry, and the liberal treatment of biochemical subjects makes it of special interest to those concerned with chemical aspects of medicine and biology.

THE DEVELOPMENT OF MANUAL SKILL

The volume on *Manual Skill, its Organization and Development*,⁶ by Dr. J. W. Cox, is concerned with problems relating to manual operations which involve the manipulation and adjustments of objects to one another. Such operations are performed for many hours every day by hundreds of thousands of our industrial workers, and it is therefore of great practical importance for us to ascertain how skill in these operations is best acquired, and whether skill acquired in respect of one operation is transferable to other manual operations which may be substituted. The investigations described by Dr. Cox are practically confined to the operations involved in the assembly of the eighteen component parts (rings, screws, porcelain base, etc.) of electric-lamp holders. They were tested very thoroughly on a group of seventy adults, and in less detail on about 200 boys and girls. A number of conclusions were arrived at which should, if confirmed, be of very great advantage to industry.

The main conclusion related to the differences induced by practice and by training. It appeared that skill developed by the repetition of one manual operation a large number of times conferred but little advantage in the performance of other operations undertaken subsequently. When, on the other hand, repetition is replaced by instruction consisting of talks, exercises based on the operation in question, and a limited number of repetitions of it, the skill thereby developed at no additional cost in time is transferable to other operations over a fairly wide range of manual activity. Moreover, the limits of proficiency attainable by training may far exceed those attainable by uninstructed repetition. These results indicate the wastage of effort produced by the customary practice of allowing beginners in assembly rooms to pick up their work as best they can, and suggest the advantages of substituting a short course of systematic training.

In other chapters of the book Dr. Cox shows that manual ability is to a small extent dependent on general intelligence, but chiefly upon the factors of mechanical aptitude and manipulative skill, and upon factors specific to the particular operation involved. Finally, he discusses in detail the subjective experiences involved in carrying out the operations of assembling, but he is too analytical in his treatment, and a more synthetic attitude might help in elucidating the theoretical basis of these valuable experimental results.

⁶ *Manual Skill, Its Organization and Development*. By J. W. Cox, D.Sc. London: Cambridge University Press. 1934. (Pp. 247, 53 figures. 16s. net.)

Notes on Books

Dr. ROY M. DORCUS and G. WILSON SHAFFER have written a book entitled *Textbook of Abnormal Psychology*,⁷ the purpose of which is to fill the needs of advanced students of psychology, pre-medical students, and medical students who desire more psychological information. Throughout the authors have attempted to approach the discussion of abnormal phenomena by means of consideration of the normal; for, as they point out, the symptoms and behaviour of abnormal individuals are not seen as new or mysterious ways of reacting, but are recognized as exaggerated manifestations of normal functioning. A vast amount of matter has been collected in this book, and some problems are discussed which have been somewhat neglected by psychopathologists. It is interesting, for example, to find an admirable discussion by the writers of this volume of the psychopathology of handedness in relation to stammering and stuttering. This voluminous work would seem to be rather a heavy meal for pre-medical students to digest.

The little work entitled "Healthier and Longer Life,"⁸ by EMILIO J. PAMPANA, contains excellent advice for the lay public concerning cleanliness, exercise, diet, ventilation, sleep, periodical visits to the doctor and dentist, the most important social diseases, prevention of acute infections, hypertension, rheumatic fever and heart disease, latent infections, especially of dental origin, and accidents.

In his short monograph on *The Atom*⁹ Dr. TUTIN propounds yet another view of atomic structure. However much physicists may differ about precise details, it is generally held that the atom consists of a massive nucleus surrounded by electrons. Dr. Tutin's alternative view reverses this: he regards the main mass as being arranged peripherally and the nucleus as being relatively light. The book is fairly entitled to the praise of being concise and short, but we think it need not seriously disturb those who hold—as most chemists and physicists do—that the main mass of the atom is in the nucleus.

Mr. ARTHUR BRYANT is well known for his researches into the history of the Restoration period in England. He has written *King Charles II*, and is producing an admirable *Life of Mr. Samuel Pepys, the diarist*. The volume on *The England of Charles II*¹⁰ is clearly a paragon or by-product of these studies, for they contain in narrative form the information which he has gathered in his reading. He tells of the sights and sounds which would have struck a foreigner on his arrival in England when the Commonwealth was giving place to Royalty; of the appearance of London and the country and of the habits and pastimes of the people. It is a book easy and pleasant to read, but as one reads it is remarkable to note how little the country life of England has changed in two hundred and fifty years, and how the English character and habits remain as they have always been. Love of travel is predominant in the English. The pilgrimages gave place to visits to Bath, Epsom, Harrogate, and countless smaller spas; these in turn have been displaced by hiking, aimless motor trips, and, more recently, by pleasure cruises. Vestiges of the old village life still remain in many parts of the country. The women work in the fields as they used to do; the saddler mends the harness with his own hands, the wheelwright and the smith work in the open, churchyards are overfull, sanitation is still rudimentary, and the water supply is scanty and bad. All this Mr. Arthur Bryant tells about, and his book gives much room for thought. The more things change in rural England the more they remain the same.

PUBLIC HEALTH CONGRESS IN LONDON

The fourth biennial Public Health Congress and Exhibition at the Royal Agricultural Hall, Islington, arranged by a council representing the Ministry of Health, the Board of Control, and municipal and county council organizations, was held last week. A very large number of discussions took place, sometimes proceeding simultaneously in three sections, and were attended by public health and sanitary officers and workers in connexion with voluntary associations from all parts of the country. The congress was opened on November 19th with a short address by Sir HILTON YOUNG, Minister of Health, who spoke again of the "drive" against the maternity death rate, and the decision to hold special inquiries in areas where the rate was abnormally high. In a reference to voluntary sterilization on the lines of the Departmental Committee's report, he called for an expression of the national mind and conscience on the subject.

The first session of the congress was occupied with an address by Sir George Buchanan, who described the international arrangements for preventing the spread of epidemic diseases. This is printed in the opening pages of our present issue.

VOLUNTARY STERILIZATION

The largest attendance at any discussion was at one arranged by the Joint Committee on Voluntary Sterilization, to consider the report of the Departmental Committee (the Brock Committee).

Professor JULIAN HUXLEY remarked that this subject was less controversial than formerly. The unanimity of the Brock Committee itself was a testimony to the overwhelming weight of factual evidence presented by sixty witnesses. Many individuals and organizations previously hesitant had been persuaded by the report to come down on the side of action, notably the Central Association of Mental Welfare. The discussion was generally confined to the case of mental defectives, but the Brock report also covered those who suffered from mental disorder and grave hereditary physical defects and probable carriers. Sterilization had nothing to do with castration, and left the sexual impulse untouched, so that it was possible and reasonable for sterilized individuals to marry. Prohibition of marriage as a means of preventing perpetuation of hereditary defect had been strongly advocated by certain people, but the great trouble was illegitimacy. The sterilizing operation was not dangerous, and over 16,000 people had already been sterilized in the United States. No responsible person in this country proposed compulsory sterilization. Voluntary sterilization was not an alternative to institutional treatment, but the complement of it. Institutions had a twofold function: to look after people not completely capable of looking after themselves, and to educate and stabilize the mental life of higher-grade defectives. When this process of stabilization had been brought to a certain point at which the people were able to live in the general community, it was then that they should be sterilized. It was true that mental defect might be due to non-hereditary causes, but half of it was distinctly hereditary, and in a great many other cases bad heredity reacted with bad environment to produce the defect. Prevention of parenthood either by segregation or sterilization was the only method whereby the burden of defect could be reduced. A further point was that mentally defective people made bad parents, and it was in the interests of the children themselves and of social justice that, wherever possible, mental defectives should not be allowed to have children. It seemed to him, as a biologist and as a citizen, that there was an overwhelming case for action. He denied that eugenics had a class bias; in fact, the legalization of voluntary sterilization would give to the poor facilities available at present only to the well-to-do. The mentality of this country would prevent a reproduction here of the developments in connexion with this subject which had taken place in Germany.

Dr. C. P. BLACKER described certain disadvantages of the Nazi method as opposed to the voluntary principle which "saturated" the Brock report. In Germany nine conditions were specified as justifying voluntary or compulsory sterilization. These included schizophrenia and manic-depressive insanity, with the result that German doctors, fearing to subject their patients to the compulsory stigma, had refrained from definite diagnosis and taken refuge in vague terms such as psychasthenia and neurasthenia. People in Germany also hesitated to go into institutions for treatment lest one such diagnosis be made and they be sterilized compulsorily. In America twenty-seven States had sterilization laws, all, except in Vermont, with compulsory clauses, but from 80 to 90 per cent. of the sterilizations in the United States were voluntary. Surgeon Commander JAMES, M.P., discussed the prospects of legislation, which, he said, depended entirely upon the state of public opinion, not upon the initiative of the Ministry of Health. A great change had taken place in public opinion, and now the only organized body in this country opposed to voluntary sterilization was the Roman Catholic Church.

Mr. GEORGE GIBSON, a member of the Trade Union Congress Council, moderately stated the case against sterilization. He urged that a Royal Commission on the subject should be set up with its proper element of lay opinion. Biologists and medical men as eminent as any who had spoken that day had reached different conclusions. The social aspects of this problem had not received adequate consideration, though they were as important as the medical and eugenic with which the Departmental Committee was exclusively concerned. He feared legislation which meant one law for the rich and another for the poor, especially when the law might entail the deprivation of elementary human rights. Public opinion—not expert opinion merely—must be persuaded and convinced that existing methods were ineffective or could not be made effective without resort to these drastic measures; also that this procedure, if sanctioned, would achieve its purpose. It was well known that from the union of normal persons mental defectives sometimes appeared, and that from the union of mental defectives (even both parents) came children sometimes remarkably endowed with intellect or character. The genetic result could not be predicted. The Brock Committee had shrunk from the responsibility of advocating compulsory sterilization because it shrunk from the necessary corollary, the setting up of a body of experts entrusted with the necessary determination. It was said that in voluntary sterilization the consent of the defective himself or of his parents or guardians must be secured. This might technically be so, but the speaker could not believe that this would in practice in a given case outweigh the opinion of the experts. The distinction between compulsory and voluntary sterilization was largely unreal; there would be no real choice. He believed that a much more searching investigation into social problems and ante-natal and post-natal environment was necessary. The environmental factors which were the cause of mental unfitness should be better ascertained before legislation was proposed. He asked whether there was any evidence that the problem was insoluble from the point of view of institutional treatment. Ought not research to be intensified into the transmission of taint? Sterilization in the final analysis was a confession of defeat.

Mr. E. W. CEMLYN JONES, of the County Councils Association, and Councillor LOXLEY, of the Association of Municipal Corporations, spoke in general support of the voluntary policy. Sir FRANCIS FREMANTLE, M.P., said there was a considerable body in Parliament not committed to the proposals of the Departmental Committee. One proposal to which Parliament would certainly not assent was that in the case of the feeble-minded their future should be decided for them by their parents or guardians. That would amount to compulsion. But if that proposal were cut out the most serious cases would go by the board, and voluntary sterilization would mean that only the more enlightened and conscientious among the mental defectives submitted themselves to the pro-

cedure. This being so, it might even prove to be a dysgenic measure.

Professor HUXLEY said in reply to this last point that already the parents or guardians of these people decided their future for them when they were segregated in institutions. The worst cases—imbeciles and so on—were dealt with by segregation now. The trouble was with the high-grade defectives, and they were the people capable of consent. He went on to urge that the process of evolution, which has led up from the lowest forms of life to the human being, could only be continued by man deliberately and consciously taking control of his own destiny. It was only during the last twenty years that control of the size of the family had taken place, and now it was proposed that man should improve the quality of his own stock. Far from being a confession of defeat, as Mr. Gibson had called it, it seemed to him the beginning of control of destiny by man in furtherance of the great stream of evolutionary progress.

BOARDING-OUT OF MENTAL PATIENTS

A less animated but useful session was devoted to the question of the boarding-out of patients from mental hospitals. Dr. W. BROOKS KEITH, medical superintendent, St. Audry's Hospital for Mental Diseases, Suffolk, said that a scheme of boarding out had been in operation there for over a year, during which time twenty-six patients had been placed in the care of suitable guardians. No difficulty had been experienced in finding guardians for women patients, but it was difficult to persuade prospective guardians to accept men. Neither the age of the patient nor the form or duration of the mental disorder was of much help as a guide in selecting cases; the point of importance for consideration was the patient's behaviour, and one had to be prepared for surprising disappointments in patients whose behaviour worsened when they got outside the institution. The ideal type for boarding-out was a case of simple dementia or the medium-grade defective without vicious propensities. This work had been done not under Section 57, of the Lunacy Act, which was the usual section for boarding out, but under Section 55, whereby power was given to visiting committees to grant to patients leave of absence on trial. Under this section the scheme had worked without the slightest hitch or difficulty, and one of the main reasons for this was the ease with which the patient might be removed from, or returned to, the hospital or transferred from one guardian to another. From the point of view of the patients he had nothing but good to say of the scheme, and whether they had been right or wrong in the way they had started it in Suffolk, he was satisfied that they had brought a little happiness into the lives of a few poor souls who were in much need of it.

Dr. A. A. W. PETRIE, medical superintendent, L.C.C. Mental Hospital, Banstead, described an attempt made there to board out a number of quiescent chronic patients either with their relatives or in foster homes. Of eighty-two patients so treated some twenty-two had returned to hospital for various causes. Mental relapse accounted for only 25 per cent. of the latter. In at least another 25 per cent. the patients definitely preferred to be in the mental hospital, having missed the entertainment and general sociability of the institution. Partial relapses were associated with inability to adjust to external conditions, but during a little over a year fifty-six patients from Banstead had been boarded out or placed on prolonged trial.

Dr. KATE FRASER, Deputy Commissioner, General Board of Control, Scotland, said that in Scotland this procedure was long past the experimental stage. There was no part of Scotland where boarded-out patients were not to be found. Indeed, in many parts there was a kind of hereditary guardianship, patients being handed down from generation to generation. One man had been fifty-four years in the guardianship of successive members of the same family. She gave unstinted praise to the guardians; the success of the scheme lay almost entirely in their hands. One great advantage of the scheme was that people in general were coming to regard patients suffering from mental illness as persons not to be shunned or feared.

At the same session Dr. REGINALD WORTH described the work of the Mental After-Care Association, of which he is chairman, and the assistance it gave to local authorities, both in after-care and in fore-care. Mr. L. G. BROCK, Chairman of the Board of Control, who presided, referred to the experience of Holland in this respect. There was an elaborate system of after-care in Rotterdam, and the Dutch superintendent had told him that it was a good investment, because it enabled the institution to discharge patients at a much earlier stage than would otherwise be possible. If the Dutch, who were a practical people, not sentimental, discovered its advantages there must be a great deal in it.

TEAM WORK IN ANTE-NATAL AND POST-NATAL CARE

A discussion on this subject took place under the auspices of the Association of Maternity and Child Welfare Centres. The principal speaker, Professor F. J. BROWN, of University College Hospital, repeated in substance his remarks in a discussion at the Royal Society of Medicine, more fully reported elsewhere in this issue. He declared that the time had come to take midwifery out of the hands of the general practitioner altogether, and to establish a service of specialists thoroughly trained in obstetrics, who, working in co-operation with highly trained nurses or nurse-midwives, would be responsible for the care of the patient both in pregnancy and during delivery. Dr. LETITIA FAIRFIELD, of the Public Health Department, L.C.C., said that they were faced with the unpleasant fact that ante-natal care had not achieved its objects. Some of the lowest maternal mortality rates in the British Isles were still to be found in large areas where ante-natal care was almost nil. It was not always realized that one of the results of ante-natal care was to protect not only the patient but the nurse and the institution by enabling them to select cases that were potentially bad maternal risks and to send them to another establishment. That was why there was so much confusion about the results of ante-natal care as relating to certain services and institutions. There was confusion also as to the connexion between ante-natal care and malnutrition. Here again the facts were all against current fashionable theories. America had one of the highest maternal mortality rates in the world, yet the standard of nutrition there was probably higher and wiser than anywhere else. No one would suggest that proper attention should not be paid to the feeding of the mother, but it would be a mistake to think that the mortality of mothers in childbirth could be reduced by concentrating on nutrition. Ante-natal care should be regarded as a link in the chain of obstetrics, not as a stunt; and the expectant mother as a woman, not as "an ambulant pelvis," as she used to be regarded in the old textbooks. Ante-natal care should consider the mother in her setting as a whole, and concentrate its forces on producing for her a good environment.

FOOD STANDARDS

Other discussions of less immediate medical interest concerned games and athletics and their value to public health, the reconditioning of working-class houses, town and country planning, and hospital equipment. Dr. W. G. SAVAGE, county medical officer for Somerset, opened a discussion on food standards in view of the report of the Departmental Committee on the Composition and Description of Food. Some bodies, he said, like the Society of Public Analysts, envisaged a system of definitions and standards ultimately to embrace all articles of food, but Dr. Savage thought such a complete series of definitions was neither practicable nor desirable. He favoured an extension of definition for many articles and for certain constituents of many foods, such as the amount of fat in cheese, and limitations for carbohydrate in sausages and the like. He considered also that all food-manufacturing premises should be registered and open to inspection and sampling by the appropriate authority; the only reliable way to control purity of manufacture; and that the present position of labelling was unsatisfactory; and that the issue of a false or misleading description should be an offence. In the subsequent discussion Mr.

L. H. LAMPITT, dealing with the chemical aspect of food control, declared the general standard of purity of food in this country to be very high. Control by standards might conveniently be established for a restricted range of products, the verification of such standards to be by accepted methods of scientific examination. But bureaucratic control engendered rules and regulations for their own sake. A representative of the manufacturers of confectionery foods, Mr. J. G. MATHIESON, said that manufacturers generally deprecated very strongly the fixing of standards, positive or negative, which could not be checked with absolute certainty by methods of analysis. Such standards put a premium on dishonesty, and no method of inspection could get over this difficulty. While standardization, so far as it had gone, had done good, he thought the Departmental Committee was wise in deciding against a hard-and-fast system of standardization applicable to every variety of foodstuff, regardless of whether any really important end was to be achieved.

MEDICAL OFFICERS OF HEALTH AT DINNER

THE MINISTER ON HIS OBLIGATION TO THE SERVICE

The annual dinner of the Society of Medical Officers of Health took place at the May Fair Hotel on November 22nd, under the presidency of Dr. R. VEITCH CLARK. The Minister of Health and Lady Hilton Young were the principal guests, and among others were Sir Arthur Robinson, Secretary to the Ministry, and Sir George Newman, Chief Medical Officer, Sir George Buchanan, Master of the Society of Apothecaries, Dr. E. Kaye Le Fleming, Chairman of Council, and Dr. G. C. Anderson, Medical Secretary of the British Medical Association, and representatives of other public services and affiliated organizations.

Sir HILTON YOUNG, in proposing the society's health, spoke of the pleasure with which, in his travels through the country, visiting places where the surroundings and even the language were unfamiliar, he had come upon "the friendly, comfortable face of the medical officer of health." "We meet here," he said, "with a warm sense of co-operation in the tasks we have to discharge." He testified to the number of occasions during his short term of office when the Ministry had sought, and never in vain, the counsel of the society. "The relations between centre and circumference in public health show steady improvement. If the rate of improvement has been accelerated during the last three years I shall be very proud. (Applause.) I thank you for that short round of applause, which I confess I had almost extorted, but this improvement of relations is due, not to any Minister, but to a steady growth in understanding as between the officers of the Ministry and yourselves. Those relations have definitely improved as a result of the Act of 1929, the good effects of which have been witnessed in the recent surveys carried out by the Ministry in co-operation with the local authorities."

Sir Hilton Young went on to speak of the "drive" for a reduction in maternal mortality, repeating some of the observations he had made on this subject at the Council Dinner of the British Medical Association a fortnight previously (*Supplement*, November 10th, p. 237). There was an armoury of services adequate to reduce the rate of mortality, but what was most required was that the standard of the backward areas should be conformed to that of the most progressive. He then passed on to speak of the evil of the slums, and said that it was upon the enthusiasm of medical officers that he relied to bring to an end in five years this intolerable evil. During this, the first year, 15,000 houses had been already completed for the rehousing of slum dwellers, and by the end of the year the construction of another 19,000 houses would be in sight. The rate at which the work had been carried on had steadily increased.

Dr. VEITCH CLARK, after paying a tribute to Sir Hilton Young for his keen interest in the public health service, said that he believed maternal mortality could be enormously reduced by the means already in existence, though there remained certain causal factors which could not be dealt with until research had been carried out to a much larger degree. Nothing that could be done in public health at present, effectively counteracted intoxications, and until more was known about the intoxications of pregnancy that section of the mortality must remain. So far as housing was concerned, in his own Manchester what had been done in replacement during the past year would be multiplied six or seven times during the next twelve months. Dr. Clark addressed himself to the younger members of the society, whom he congratulated on living in the greatest age that public health had ever known.

Sir JOHN ROBERTSON then proposed the health of two veteran workers for the society, both of whom had held every high office in it—Dr. T. W. Naylor Barlow of Wallasey, and Dr. G. F. Buchan of Willesden. He recalled the long fight for the status and remuneration of the medical officer of health—a fight in which the society had been splendidly assisted by the British Medical Association. Dr. NAYLOR BARLOW, in a breezy reply, spoke in his turn of the value of the society, in which he had learnt the experience of other men and been able to add it to his own. He contrasted the present day of recognition with his own early experience as medical officer of health for Bootle, when there were six doctors on the town council, all of whom looked upon the medical officer of health as an interloper and of much inferior status, and when his office was a partitioned-off portion of the common reading room. Dr. G. F. BUCHAN, in his reply, said that in the science of public health there was no such thing as finality. They had to unlearn much that they had been taught, and to undo much of their teaching of others. In these circumstances perhaps it was not surprising that Ministers of Health and health committees did not always attach the same importance to their schemes that they did themselves. He regretted the frequent absence of one type of worker from a health department—namely, the research worker. Science could never be a closed book, and the health department which did not base its methods on experimental medicine and research would not make the progress that it ought.

The toast of "The Guests" was proposed by Dr. T. N. V. Potts. In replying, Dr. J. S. FAIRBAIRN said that in the double capacity of chairman of the Central Midwives Board and president of the British College of Obstetricians and Gynaecologists he saw a good deal of the medical officer of health, and from different standpoints. He had often had to tell medical officers of health that they might know a great deal of preventive medicine, but they had much to learn about preventive obstetrics. On the other hand, he found in the British College that some of his colleagues did not get the right view of the medical officer of health, whom they thought of as representing local bureaucracy. He added that he had worked for a long time for a diploma specially designed for maternity and child welfare workers, but his great difficulty had been to get medical officers of health to make any use of it. In a further reply, Sir GERALD HURST, K.C., the senior member of Parliament for Manchester, bore testimony to the work of Dr. Veitch Clark in that city, which he acclaimed as the pioneer and pathfinder in all social progress.

According to S. D. Collins and M. Gover (*Bull. Off. Internat. d'Hyg. Publique*, October, 1934), who record their observations on influenza in ninety-five towns of the United States during the winter of 1932-3, that the epidemic was one of the least important of the nine which have occurred during the period 1920-33, but was the most considerable of those since the epidemic of 1928-9. The mortality was higher in the Western than in the Eastern States. The West Southern Central States were first affected, and the disease then spread simultaneously to the west, north, and east, New England being the last to be attacked.

INTERNATIONAL HEALTH

During the early part of the nineteenth century the intrusions of plague and cholera into Europe led to the adoption by various countries of measures designed to arrest these infections at their port of entry. Of these measures it may be said in general that they were more rigorous than effective, and in 1851 the situation in the Levant had become so serious that a conference was held in Paris between representatives of the States interested in order to arrive at a mutual understanding on some common course of action. So far as England was concerned the official view about this time appears to have been strictly insular. The presence of cholera in the world at large was no doubt unfortunate, but the fear of it had been a strong incentive to the improvement of English water supplies and sanitation, and so the Government of the day, while not exactly welcoming the cholera, took no official action against it, but left it to the seaport towns to exercise locally such powers as they had when an outbreak threatened.

Later, in 1896, a new problem was raised by the seaborne extension of plague from Bombay. In 1897 a conference met at Vienna to concert new efforts, and in 1903 the Sanitary Conference at Paris proposed an international Convention for both plague and cholera. Except, however, the Constantinople Superior Board of Health and the Egyptian Quarantine Board, which had limited fields, there had hitherto been no standing organization to deal with international quarantine. The opinion grew that such an organization had become necessary, since only by continuous expert study and periodical meetings between representatives could the obligations which Governments should jointly assume be fixed with any prospect of success. This opinion, which took formal shape at the Rome conference of 1907, materialized in 1909, when the Office International d'Hygiène Publique began work in Paris. During the four years of war the activities of the Office were in abeyance. With the return of peace they were revived. The question then arose of the relationship of the Office to the new Health Organization, as it was called, of the League of Nations, and after sundry procedure a liaison was devised under which the two bodies would act in co-operation.

The happenings above summarized are recounted in more detail by Sir George Buchanan¹ in his Milroy

Lectures, recently issued in book form. They provide a fitting prelude to his interesting review of what has been attempted and achieved in international hygiene, which he supplements in the address printed in our opening pages this week. Under the auspices of the Health Organization, as he says, the Commission on Biological Standardization has rendered important service to medicine. The Malaria Commission has thrown valuable light on the control of that disease, indicating that the methods employed must be adapted to local conditions. The Cancer Commission has made a comparative study of cancer statistics, and in connexion with radium treatment has suggested a standard nomenclature together with standard methods of case recording and the following up of treated cases. Health missions have been active in Eastern Europe, Latin America, the Pacific Islands and elsewhere, and the Far Eastern Bureau has afforded facilities for the pooling of information regarding the progress of infection in the Orient. The Office International, as a standing supervisory body, perseveres in serving the object for which it was originally brought into being. Regularly at its half-yearly sessions its members review the needs of the world according to the changing incidence of disease and the growth of epidemiological knowledge. The International Sanitary Convention of 1926 extended co-operative action to typhus and small-pox, and in the case of plague established the six-monthly examination of ships at designated ports to ascertain whether they needed "deratization"—that is, riddance of rats. The Sanitary Convention for Aerial Navigation of 1933 is another example of the progressive policy of the Office.

In the note with which he concludes the Milroy Lectures for 1934 Sir George Buchanan refers to the *co-partnership between the Health Organization and the Office*, and touches upon the seeming anomaly that questions which are essentially dependent on the joint action of Governments should be thus dealt with by two committees in two separate capitals. As one familiar with the work and well qualified to speak he expresses the view that there are advantages in the arrangement, and that the duplication, such as it is, gives relatively little trouble. Should, however, any question arise of further readjustment, throwing into relief competing claims by the two bodies, it seems to us that there might be much to say on behalf of the Office. Having weathered first the World War and later the coming into existence of so highly accredited a rival as the Health Organization of the League of Nations, the Office would appear to be possessed of a strong inherent vitality or power to resist administrative shocks. Such a tendency to permanence was one of the aims of those by whom the formation of the Office was first mooted. It is of signal importance to the work which it carries on, and for the purposes of that work it is linked not only with European Governments but also directly with many of their overseas dominions and possessions.

¹ The Milroy Lectures on International Co-operation in Public Health: Its Achievements and Prospects. By Sir George S. Buchanan, C.B., M.D., F.R.C.P. Reprinted from the *Lancet*, April 28th, May 5th and 12th, 1934.

DRILLING IN PHYSICAL SIGNS AND DIAGNOSIS

That it is easier to instruct advanced students, or at least those who have mastered the elements of the science of medicine, than to teach students on the threshold of their long course, is generally recognized. It is often acted upon by the professor taking the introductory course of lectures and deputing his lecturers to undertake those on the more advanced aspects of his subject. In the case of physical diagnosis as a preparation for work in the medical and surgical wards this plan was formerly not adopted; but since their institution after the war the professorial units have in general undertaken this duty, which, though a tribute to their efficiency, has added to their labours, and may have interfered to some extent with activities in research. The teaching of physical signs and diagnosis varies in method and duration. Perhaps the most important aim in these classes is to initiate what should become an almost unconscious process of routine in examination and observation. The meaning and bearing of this faculty may perhaps be illustrated by a comparison made by a junior colleague of two of his seniors: one physician remarkable for flashes of diagnostic genius, the other physician characterized by his rule-of-thumb custom of methodically examining (1) the tongue, (2) the pulse, and thus conscientiously going over the patient, but with the result that he sometimes wiped the eye of his more brilliant colleague. Lest any attempt to identify those concerned in this comparison should thus be stimulated, we may add that they have "passed beyond these voices."

Among the instructor's difficulties in successfully inculcating this mental habit of approach to clinical examination of patients is that of finding out how much his students really do see and actually feel or hear when examining the patients brought for demonstration. Realizing this to the full, Professor Logan Clendening of the University of Kansas has adopted a system whereby the students take notes detailing their observations as they make them, which the instructor then reads, and so obtains the desired insight and the opportunity of giving further help. In his pamphlet, *The Laboratory Notebook Method in Teaching Physical Diagnosis and Clinical History Recording*,¹ he sets out, in addition to a tabular scheme of note-taking, eighteen "exercises" which in some respects constitute examination papers on the cases investigated, especially with regard to the part of the body thought to be affected. Thus questions are asked such as: "Is the disorder organic or inorganic?"; "What do you hear over the second interspace to the left of the sternum?"; "What valve area is this?"; and, "Is the Romberg test positive?" In this connexion reference may be made to a useful brochure by Dr. T. R. Parsons of Sidney Sussex College, Cambridge, entitled, *Lectures,*

Reading and Examinations,² which gives much useful advice, based on experience and sympathetic understanding of the student's problems. Thus in dealing with note-taking at lectures the laborious process of making a fair copy of notes taken down at the time is strongly deprecated as merely a tedious waste of time; and as a substitute the student is directed to leave plenty of space between the lines of the original transcript and the opposite page blank for subsequent expansions and corrections. A system of abbreviations should be invented and employed by the student, who, if possessed of a "photographic" memory, should fill his notebook with diagrams. Reading on the same subject as the lecture should follow, and also be accompanied by note-taking. Finally, as regards examinations the advice given is equally sound, and the importance of early to bed is underlined by the *obiter dictum* of a well-known coach that "every minute after 10 p.m. means a mark lost in the examination next day."

PHRENICECTOMY

Phrenicectomy has during the last few years become a popular operation in this country. Both artificial pneumothorax and phrenicectomy are comparatively minor operations, and therein lies a certain danger that they may be practised indiscriminately, and often without careful selection of cases, on the justification that they can at least do no harm. Any new procedure is bound to go through a probationary period. In the case of phrenicectomy this period is over, and it is time that those who have had considerable experience published their results. More valuable information can be obtained by a consideration of the results in small comparable groups than *en masse*. A very useful contribution along these lines has just been published in France by Emile Sergeant, Launay, Bonniot, *et al.*³ These authors start with a review of the physiology of the phrenic nerve and the effects of its paralysis. It will be news to many that the phrenic nerve carries sensory fibres from the lumbar peritoneum, but this will explain the apparently "hysterical" association between a lesion in the abdomen and a pain in the neck. Both Sergeant and Launay are strongly opposed to the routine practice of paralysing the diaphragm when an artificial pneumothorax has been indicated but has failed. In the treatment of pulmonary tuberculosis these authors are agreed that the effect of a phrenicectomy on a pulmonary cavity does not depend so much on the position of the cavity as on the character of the surrounding parenchyma. When the cavity, either at the apex or at the base of the lung, is surrounded by dense sclerotic lung tissue, paralysis of the diaphragm will not assist its closure; when, however, the cavity is thin-walled and surrounded by a recent infiltration, considerable improvement or closure of the cavity is to be expected from this operation. Bonniot considers

³ *Arch. Med.-Chir. de l'Appareil Respir.*, 1934, Tome IX, Nos. 1 and 2.

that an isolated cavity of the favourable type described above, and which has improved up to a point under sanatorium regime, is best treated by a phrenicectomy as a primary procedure. Undoubtedly artificial pneumothorax is not without risks, and if the same result can be obtained by a phrenicectomy it is surely the method of choice. By crushing a phrenic nerve and removing the accessory fibres a temporary paralysis is obtained, which overcomes the disadvantage of an irrevocable procedure. The authors are also against the routine practice of phrenic avulsion prior to thoracoplasty. Bonniot considers that it should only be employed when the lesion is of the type that will improve under this treatment. Thoracoplasty should then be delayed until the maximum improvement has been obtained. Sergent states that he has never seen phrenicectomy benefit cases of acute pneumonic tuberculosis. To apply it to suppurative conditions of the lung, particularly to bronchiectasis, has always seemed an irrational procedure. H. P. Nelson¹ has already given a warning against collapse therapy in bronchiectasis. The French writers consider that its results for suppurative diseases are inconsistent and unreliable, that it is definitely contraindicated where there is an active inflammatory lesion in the parenchyma, and that in bronchiectasis it provides only a temporary improvement. On the whole, phrenicectomy in pulmonary tuberculosis has given, in the carefully selected cases, very good results; sometimes it fails in its object, but it rarely does harm. The contrary must be said of this operation in suppurative diseases—namely, that it rarely does good, sometimes produces no effect, but usually makes the condition of the patient worse.

A RECEPTION AT APOTHECARIES' HALL

The various gatherings of public health workers in London last week culminated in a largely attended reception given on the evening of November 23rd by the Society of Apothecaries of London, to meet members of the Society of Medical Officers of Health. The guests were received in the fine old hall by the Master, Sir George Buchanan, the Senior Warden, Sir William Wilcox, and the Junior Warden, Dr. J. S. Fairbairn. The early part of the evening was devoted by the visitors to an examination of the many treasures of which the society is the proud possessor. Attention was specially drawn to the licence to use the hall, granted by Charles I under the Great Seal and dated 1634. Another valued exhibit was the laboriously lettered and illuminated scroll conveying the appointment of two apothecaries to the court of Charles II. There was also a costly snuff-box given by the City of London to Edward Jenner. The principal exhibits were the old medical books, some of which had a special interest for health officers. The overcrowded title-page of one, dated from before the Great Fire, described the contents as "Certain necessary directions as well for the cure of the Plague as for preventing the infection, with many easy medicines of small charge very profitable to his Majesty's subjects. Set down by the College of Physicians." "A New Herball," dated London, 1551, in which were included "a booke of the bathes in England, in Germany and Italy," and "A Homelye

Physicke Booke," created much interest, and another, described by the society's curator as one of the rarest medical books, was "An Account of the Medical Uses of the Foxglove." Others were "A Plain Philosophical Demonstration of the nature, faculties and effects of all such things as by way of nourishment make for the preservation of Health, with divers necessary observations; as also of the true use and effects of sleep, exercise, excretions, and perturbations," by T. Venner, Bath, 1638, "whereunto is annexed an accurate treatise concerning Tobacco"; and a volume published in 1596, written by Nicholas Monardus and "Englished by John Frampton, Merchant," entitled "Joyfull Newes out of the New-found World," and describing "things brought from the Occidental Indies which serve for the use of medicine." After the inspection of these exhibits a move was made to the Great Hall, standing unaltered, except for its Adam ceiling, from the days before the Great Fire.

THE FATHERS OF ODONTOLOGY

The Royal Dental Hospital of London has just completed its third quarter of a century, and occasion was taken by the chairman, Mr. J. Thornton Carter, at the annual dinner of the staff and past and present students, on November 24th, to praise its founders. Odontology was gaining recognition as a science more than thirty years before the Royal Dental Hospital came into being—witness the work of Cuvier, Richard Owen, and Thomas Bell. But the institution, said Mr. Carter, started its life at just the right time and in an atmosphere where every breath was stimulating. In the same year that saw the foundation of the hospital—1858—Darwin and Wallace read before the Linnean Society their paper advocating the theory of natural selection, which was to influence the progress and direction of every branch of biological knowledge; Michael Faraday at the Royal Institution demonstrated certain phenomena in solutions of gold—the colloidal state—which led at once to far-reaching results and to-day seemed to be opening boundless horizons; Claude Bernard was publishing his memoirs on the pancreas and the role of pancreatic secretion in digestion; Pasteur was publishing his paper on fermentation; and Mendel was formulating his laws of inheritance. At that time Sharpey was professor of anatomy and physiology at University College, London, and Grant, who inspired much of John Tomes's work, occupied the chair of comparative anatomy. It was a time when every branch of science seemed to be developing broader and grander conceptions. John Tomes was an original member of the staff, and in the second year of the hospital he published the first edition of his *Dental Surgery*. Later Charles Tomes published his *Manual of Dental Anatomy*, where his chapter on the evolution of the forms of teeth remains a masterly contribution on the various factors underlying the progressive changes in dental structure. A fellow student of Charles Tomes at Soho Square was Howard Mummery, whom Mr. Carter considered to be the greatest of dental histologists. These men he named as the founders of odontology, and the staff of the hospital and school had since seen an unbroken succession of distinguished names, often illustrious son

¹ *British Medical Journal*, January 13th, 1934, p. 58.

following illustrious father. Mr. Carter mentioned that during the history of the hospital there had been eleven consulting surgeons on the staff, of whom he had known eight, and there had been six deans, and he had fallen under the jurisdiction of four. That the hospital is continuing to fulfil the ideals of its founders was shown by the multitude of demonstrations and exhibitions at an "At Home" preceding the dinner, when the conservation room, the mechanical laboratory, the x-ray department, the orthodontic and research departments, and the museum were filled with eager exhibitors and students; it was shown also by the speech of the dean, Mr. H. Stobie, in recounting the past year's progress. One development has been the institution of a foundation scholarship at Epsom College, to be awarded to a student working for the D.D.S. degree. The Rev. A. C. Powell, head master of Epsom, acknowledged this practical compliment and hoped that in the future it would be seen that his school could turn out first-rate dentists as it had turned out first-rate doctors.

BRITISH MEDICAL QUALIFICATIONS IN INDIA

The position created by the Indian Medical Council Act, 1933, with regard to the recognition of United Kingdom medical qualifications in India is referred to in the recent report of the Joint Committee on Indian Constitutional Reform.¹ The Act, it will be remembered, set up a medical council for the whole of India with substantially the same functions as those of the General Medical Council, and scheduled the medical diplomas granted by institutions outside British India—including the registrable qualifications of licensing bodies in the United Kingdom—which were to be recognized in India for purposes of the Act. It also provided that this schedule should remain unaltered for four years, but that the Indian Medical Council should be empowered to negotiate with an authority in any country for a scheme of reciprocal recognition of medical qualifications; that the Governor-General should be informed of the decisions of the Council to recognize, or to refuse to recognize, the medical qualifications proposed by other countries; and that the Governor-General should frame a new schedule to become effective four years after the commencement of the Act, which should comprise the medical qualifications thereafter to be recognized. Provision was also made enabling the Governor-General, after the expiration of four years, to amend the schedule and to add further qualifications or to recognize only qualifications granted before or after a specified date. The report comments as follows:

"We appreciate and sympathize with the efforts of the Indian medical profession to put its house in order, and we hope that co-operation between the two Councils will go far to ensure an amicable and agreed solution of the present difficulty. . . . We are of opinion that the Indian Medical Council Act, with only slight modifications, can be made the basis of a permanent and satisfactory arrangement. . . . But we confess that we should find difficulty in agreeing that the Governor-General is an appropriate authority for determining whether any particular qualification should be recognized. . . . We think that the true solution is to be found in an adaptation of the provisions in the United Kingdom [Medical] Act, whereby any refusal by the General Medical Council to

recognize a medical diploma granted abroad may be made the subject of an appeal to the Privy Council; and we suggest that if after the expiration of four years the Indian Medical Council proposes to withhold recognition of any of the United Kingdom qualifications an appeal should lie to the Privy Council, whose decision should be final. The Act of 1886 requires the Privy Council, before giving its decision, to communicate with the General Medical Council, and there should be a corresponding provision that in the converse case there should be communication with the Indian Medical Council; but we are disposed to think that the law should be amended so as to provide that in either case both Councils should be communicated with before the decision of the Privy Council is given. We hope that before the four years have expired, as a result of joint action between the two Councils, the General Medical Council will have seen its way to restore its recognition of Indian diplomas,* and that discussions may proceed between them free from political influence or bias and with the sole object of promoting the interests of medical education in both countries."

Concerning the Indian Medical Service the report states: ". . . the members of the Service ought, by virtue of the commissions which they hold, to be deemed to possess all necessary statutory qualifications entitling them to practise."

THE CASE HISTORY IN OPHTHALMOLOGY

From the opening paragraphs of Mr. Bishop Harman's *Aids to Ophthalmology* more than a few generations of students have become acquainted with the aphorism of the late Sir George Murray Humphry: "In surgery eyes first and most, fingers next and little, tongue last and least." Ophthalmologists, perhaps because they can see so much, do on the whole tend to listen too little, though mature experience inclines them in general to attach more and more importance to the history as given by the patient. Dr. Harald Gjessing,¹ in a paper before the North of England Ophthalmological Society, while not exactly leading a revolt in favour of the tongue as against the eye, has made a convincing plea for the lingual organ—the patient's, not the surgeon's. In stressing the value of the history and of spontaneous statements by the patient, Gjessing has drawn, charitably enough, on the mistakes he himself has made by listening too little. But no ophthalmologist will be deluded into believing that Gjessing's confession of sins does not carry the gentle reproach *de te fabula narratur*. Speaking of pain, he quotes with approval a saying of one of his colleagues, that "pain is the Lord's greatest gift to humanity: this alone makes the patient call on the physician in time." While not blind to the pitfalls awaiting the unwary in being attentive to symptoms to the exclusion of a systematic examination, Gjessing goes rather far in his interpretation of the type of pain associated with different lesions. How many ophthalmologists would subscribe to his dictum that with an ocular pain reminiscent of toothache and becoming worse during the night, especially in the early morning hours, involvement of the ciliary body may safely be diagnosed? He is on less debatable ground in stressing the value of the patient's history of subjective symptoms in glaucoma, for glaucoma still awaits physical means of early diagnosis.

* This recognition was withdrawn by the General Medical Council some four years ago. (See *British Medical Journal*, 1930, i, 508.)
¹ *Arch. of Ophthalmol.*, 1934, xii, 330.

¹ H.M. Stationery Office, 1934. (Is.)

An interesting point he makes is that some patients find that the taking of such stimulants as coffee will produce symptoms suggestive of prodromal attacks of glaucoma (which to Gjessing are really abortive attacks of congestive glaucoma). Of interest, too, are his remarks on asthenopia; but here we feel that he is letting his enthusiasm run away with him when he subscribes to the views made popular by the late Dr. Gould in regarding Huxley, Darwin, George Eliot, Robert Browning, and De Quincey as victims of undiscovered hypermetropia. Another side of the picture is the case in which a too convincing history leads the examiner astray. Cases of cerebral tumour diagnosed as migraine come under this consideration, while a patient's emphatic belief that he has suddenly lost the sight of one of his eyes may be based on nothing more than his being forced to use an eye which he did not know was defective. Few ophthalmologists will fail to recognize their own mistakes in the case histories related in this able paper—not excluding the one in which the patient was boasting that he "had made fun of Dr. Gjessing," though to be sure a wrong diagnosis is no matter for fun, least of all when it involves, as in this case, the overlooking of a cerebral tumour.

THE STRANGWAYS RESEARCH LABORATORY

Twenty-one years have elapsed since the founding in 1912 of the Strangeways Research Laboratory at Cambridge as a small hospital for the treatment and study of the conditions coming under the general definition of chronic arthritis. The annual report of this institution for 1933 appropriately reviews the growth and development of the laboratory since its start. After a determined but relatively unsuccessful effort to advance towards a solution of the problem of this disease along the lines of orthodox pathology, the late Dr. Strangeways converted the wards into laboratories, and collected a small group of investigators to study the processes of normal growth and of the influences determining and affecting them. The laboratory thus became one of the earliest centres in this country to take up the artificial culture of tissues. For many years now the Medical Research Council has made grants for the support of certain members of the staff and sums totalling more than £10,000 to meet general expenses, the Royal Society has endowed a Fellowship, and private donors have given generous aid. Since the opening day in 1912 there have been eighty-four persons accommodated in the laboratory as research workers or students, and eighty papers have been published, twenty of these during the last twelve months. In 1933 there were more workers in the laboratory than in any previous year. Every room in the building is occupied, and there is urgent need for further accommodation. To such an efficient and fruitful organization have the early devoted enthusiasm and self-sacrificing struggles of Dr. Strangeways led. Since its main objective has always been the elucidation of the normal development and differentiation of growing tissues, the laboratory work has become of special interest to cancer workers. Radiation therapy holds out an increasing promise of amelioration, but for its effective and safe application there is needed a much fuller knowledge of the mode of action of different kinds of rays on normal and

malignant cells. Only such a diverse and patient study of the reactions of cells cultivated in artificial isolation as is conducted in the Strangeways Laboratory can promise this. Such work may also reveal the causes of maldevelopments, and the way to their prevention or correction. Much of the current report is devoted to statements of the researches at present in progress. One investigator has shown that the growth, differentiation, and calcification of bone in endosteal cultures which are grown in plasma and liver extract from a bird deficient as regards vitamin D are considerably retarded as compared with similar cultures grown in a medium derived from a normal bird. A high concentration of calciferol has a strongly toxic effect, and almost inhibits growth. By cultivating bone in media derived from birds suffering from D-hypervitaminosis indications have been obtained that, while growth may be accelerated, differentiation is not more rapid than when ordinary media are employed. A report on the mechanism of calcification in cartilage and bone is to be published shortly. Another researcher has shown that when a fragment of the primitive streak is transplanted into the extraembryonic part of the fowl blastoderm it may induce an embryonic rudiment in the host tissue. The correlation of the glycogen and fat content of early embryonic tissues with their growth and development is being studied. It has been found that with compact bone cultures exposed to radium rays filter disks of various substances are more protective when placed 3 to 4 mm. from the explant than when close to the preparation. This effect has not yet been seen with powdered or cancellous bone, and the unexpected result is being investigated more intensively. Gamma rays do not seem to interfere with the rate of progress of mitosis of living dividing fibroblasts. With its fine record of achievements in the past and its present energetic progress, the laboratory, which has already won high commendation at home and abroad, may confidently look forward to an increased measure of support, which will enable it to fill even more adequately its most valuable part in the field of developmental histology.

FOOD-POISONING BY DUCKS' EGGS

W. Fromme¹ reports on nineteen outbreaks of food-poisoning occurring during the past two or three years in the Ruhr district of Germany due apparently to the consumption of ducks' eggs. Ninety-nine persons were affected, and four of them died. *B. aertrycke* was responsible for fifteen and *B. enteritidis* Gaertner for four of the outbreaks. Clinically the picture was usually of the acute gastro-enteritis type, but mild attacks were very common, and sometimes a paratyphoid-like fever developed after an incubation period of a few days. In no fewer than seven of the outbreaks the vehicle of infection was a potato salad with mayonnaise made from ducks' eggs. As a rule the eggs were used raw, but in some outbreaks they had been boiled, fried, or heated lightly. Inquiry showed that imported eggs from Holland were responsible for most of the outbreaks, though some were due to eggs laid locally. Nearly all the infected eggs appeared to have come from one breed of duck—the Khaki-Campbell—though

¹ Arch. f. Hygiene, October, 1934.

Indian runners were definitely incriminated in one outbreak. Infection is apparently very common in duck establishments in Holland, where sometimes as many as 80 per cent. of the young ducks are stated to have died of epidemic disease. The eggs are often contaminated on the outside with faeces containing the causative organism, so that disinfection of the shell may diminish the risk of human infection. But in some eggs the interior is also infected, and even cooking cannot be relied upon to render them safe. One of the most important preventive measures is to institute a proper bacteriological control over duck farms.

DIPHTHERIA IMMUNIZATION IN LENINGRAD

P. F. Sdrowsky¹ has recently reviewed the results of compulsory immunization against diphtheria of 158,246 children aged 1 to 7 years. The anatoxin used was prepared in Leningrad according to the Pasteur Institute methods, and contained on the average eight to twelve antigen units per cubic centimetre. The complete course of immunization consisted of three injections: 0.5 c.cm., followed in twenty days by 1 c.cm., followed in fifteen days by a further 1 c.cm.—giving a total of twenty to thirty antigen units. The serological effectiveness was tested by the Schick reaction in 3,699 immunized children; it was found negative in 90 per cent., doubtful in 4 per cent., and positive in 6 per cent. A control group of 224,568 children was not immunized. In the immunized group 12.8 children per 10,000 subsequently contracted diphtheria, while in the control group the morbidity rate was 119.7 per 10,000, or 9.73 times higher. The mortality rate was 0.28 per 10,000 in the immunized group and 7.88 in the control group. Intensification of the immunization by raising the antigen content of the anatoxin gave still better results as regards both serological effectiveness and the morbidity and mortality rates. On the basis of this mass experiment the author strongly advocates wider adoption of compulsory diphtheria immunization.

GENERAL MEDICAL COUNCIL ELECTION

The result of the voting in the recent election of a direct representative for England upon the General Council of Medical Education and Registration of the United Kingdom was as follows: Sir Henry Britten Brackenbury, 9,317 votes; Dr. Edward Andrew Gregg, 2,665 votes; Dr. Mabel Lida Ramsay, 2,346 votes. Sir Henry Brackenbury has accordingly been elected a member of the General Medical Council representing the registered medical practitioners resident in England, for a period of five years from January 1st, 1935.

The Thomas Vicary Lecture will be given at the Royal College of Surgeons of England by Professor William Wright on Thursday, December 6th, his subject being "Galen and the Eye." The Bradshaw Lecture, on "The Functional Derangement of the Intestine that follows Abdominal Operations," will be given by Mr. Victor Bonney on Thursday, December 13th. Both lectures begin at 5 o'clock.

A LANDMARK IN NEUROLOGY

JUBILEE OF FIRST OPERATION FOR REMOVAL OF CEREBRAL TUMOUR

In celebration of the jubilee of the first operation for the removal of a cerebral tumour (which was performed by Sir Rickman Godlee at the Hospital for Epilepsy and Paralysis, Maida Vale, then in Regent's Park, on November 25th, 1884) a lecture was delivered under the auspices of that hospital by Mr. WILFRED TROTTER in the Barnes Hall of the Royal Society of Medicine on November 27th. Dr. WILFRED HARRIS presided over a distinguished company of neurologists and others.

Mr. Wilfred Trotter began with a comment on the custom of ceremonial commemoration of past events. Such celebrations, he said, were apt to lead to a loss of proportional emphasis unless the attitude of approach were clearly defined. It was desirable to beware of any strong tincture of that antiquarian spirit which delighted in the doings of a past generation just because they were old-world and quaint. The pious laudation of departed greatness was a good exercise in its place, but perhaps it was desirable to recall Samuel Johnson's remark that a man was not on his oath when framing an epitaph. Nevertheless, such commemorations had their value. The immediacy of contemporary events concealed their full quality and outline. It was only past events that could be seen as part of the pattern of things with an approach to substantial reality.

THE GOLDEN DECADE

The lecturer went on to place in its time-setting the event which was being commemorated. Fifty years was well within living memory, yet what a gulf between 1884 and now. The middle 'eighties were the richest period of the Victorian era. The warm, tranquil air of security of that age closed around us. Its stability was embodied in the everlastingness of its central figures—Victoria, Gladstone, Bismarck. The British Empire was soon to gain its voice, which it did at the jubilee of 1887, and by the diamond jubilee ten years later that voice had already become a little strident, and the light was perceptibly that of evening, with the shadows long on the ground. But the golden decade of the 'eighties seemed in memory bathed in the timeless light of a summer afternoon, though there were occasional rumblings on the horizon, and at the very time when this group of doctors were watching their patient with declining hopes, General Gordon in the Sudan was facing a doom as inevitable as the sick man at Regent's Park.

The story of the surgical event had lately been retold by Sir D'Arcy Power. The patient was a man of 25, who for three years had shown symptoms which pointed to tumour of the brain. He had Jacksonian attacks, and three months before admission to the hospital he had had to give up his work owing to the uselessness of his left arm. He suffered from severe pressure symptoms, intense headache, and uncontrollable vomiting. Diagnosis was made of a tumour, probably of minimum size, involving the cortex of the brain, and situated in the middle part of the fissure of Rolando. The patient was intelligent enough to understand and brave enough to accept the course proposed by the doctors. The tumour was removed in an operation in which one cerebral convolution was exposed—the ascending parietal as was afterwards proved—and was found to be a glioma about the size of a walnut.

The immediate effect of the operation was satisfactory. Most of the symptoms were relieved, and intelligence was fully retained. It was thus proved for the first time that without the least external abnormality a lesion of the brain substance could be removed, leaving the general functions of the brain unimpaired. Complete success, however, was denied the surgeons; an infection of the wound occurred, and death followed after four weeks. If these pioneers were unfortunate in their efforts to exclude infection, they were fortunate in having as their first case one in which the neurological and anatomical localization of the lesion could be made so brilliantly exact.

GODLEE, HIS CONTEMPORARIES—AND THE PATIENT

The patient was under the care of Hughes Bennett and Rickman Godlee, and there were also present at the operation Ferrier and Hughlings Jackson. Bennett seemed to have been the thoroughly competent son of a distinguished father, Hughes Bennett of Edinburgh, who incidentally introduced the use of cod-liver oil. Godlee at the time of the operation was in his early prime. He had been on the staff of University College Hospital for seven years, and was to serve it for thirty more with characteristic punctuality, assiduity, and never-failing loyalty. It was the healthy tradition of the students at that hospital to look upon their seniors with an unsentimental and not too indulgent eye, but the greatness of Godlee could not fail to impress itself. They saw him as he was, and he saw them as they were—and did not always conceal the result of his observation. His precise, patient, and extremely lucid teaching was invaluable, not only for its excellence, but for the regularity with which it was dispensed, even in his busiest years. He was never harsh, but his confidence was difficult to win, and he was an exacting chief. The lecturer said that he could speak only for one of his pupils, but it took that one quite a long time to guess at the sensitiveness and personal humility which he concealed from the world by means of a tongue always clever and sometimes a little cruel.

It was scarcely possible to estimate the quality of Godlee without a glance at the men who were his contemporaries—Barker, his senior by one year, and Horsley, his junior by seven. The jubilee year of Queen Victoria—at whose express wish Victor Horsley bore his first name—was marked by notable events, but by no event more notable, though to the general public quite unregarded, than the first removal by Horsley of an accurately localized spinal tumour. Horsley's mind concentrated on special problems, though, when he chose to use it, he had an extraordinary flair for all clinical matters. Godlee, on the other hand, was a single-minded clinician. For him the task of the surgeon was to teach the practice, the established doctrines, the rules of the art. His attitude to surgery was, therefore most certainly, in the best sense, academic and authoritarian.

It was paradoxical that a man such as Rickman Godlee should have been engaged in the daring adventure that attack on a cerebral tumour must then have seemed, and no doubt Godlee approached it with at least all the qualms any conscientious surgeon must have felt. He would be sustained, however, by the knowledge that he possessed two very special qualifications. In the first place, as the nephew of Lister, he would feel able to apply the new antiseptic doctrine in all its purity, might even feel an almost apostolic mission to demonstrate its value in the unknown region of the brain. In the second place, the knowledge that he was a highly competent anatomist must have encouraged him in the difficult task of finding his way through such an operation. "It is pleasant to think with what relief and pride the young, conscientious, and perhaps not very self-confident surgeon must have concluded an operation that so brilliantly justified every expectation and so generously rewarded every effort." No such happy combination of circumstances seemed to have befallen Godlee again. Whatever satisfactions he was to enjoy he was not to experience any more the exultation of leading a forlorn hope.

One other person was present at the operation—indeed, his presence was indispensable at all operations, though he was usually designated by initials—namely, the patient. In this case he was young, intelligent, and courageous, and he was to die. His name was Henderson, a native of Dumfries. "I feel a pious satisfaction," said Mr. Trotter, "in being able to add the name to the exiguous roll of those by whose misfortune or endurance the world has directly gained. It is a strange defect in medical history that so few of the names of these benefactors have been kept. To the high professional spirit the mention of such names may be trivial, even a little ludicrous, but let us not forget that these are the names of those who have borne more substantial witness than philosophers or theologians that all suffering is not in vain."

THE EVOLUTION OF BRAIN SURGERY

It remained only to discuss the special context of the event. This first operative removal of a localized cerebral tumour marked the convergence of two distinct processes—the evolution of operative surgery on the one hand, and of neurology on the other. The first essential fact of an operation was that it should be anatomically and physiologically possible. In that way originated most of the classical operations—amputations and excisions which were in essence anatomical, without primary orientation to any disease. Afterwards it became possible for the operation to be oriented specifically for a given lesion. Hence the full development of operative surgery was strictly dependent on pathology. At one time—by the middle of the nineteenth century—surgical pathology had got far ahead of surgical treatment. It seemed doubtful at that time whether wound infection would not bring surgical progress to a standstill. The Listerian system abolished that anomaly, and there was an immediate harvest of success. But where surgical pathology had made little or no progress, there the antiseptic method could gain little or no immediate result, as, for example, in abdominal surgery until near the end of the nineteenth century, and thoracic surgery until the beginning of the twentieth. It was the good fortune of surgery of the brain that it came at a time when everything converged—when there was no tendency for operative inventiveness to outrun pathological foundations, as happened in other fields occasionally.

The lecturer concluded with a reference to Hughlings Jackson and David Ferrier. He reminded the audience of the classic contributions to neurology which both these men had made in the early 'seventies, and without which the operation commemorated would not have been possible. They it was who were responsible for the vigorous neurological expansion of that period. He could not forego adding that Ferrier's great paper, which gave a great impetus to the whole study and confirmed the clinical work, was published in the *Clinical Report of the West Riding Lunatic Asylum for 1873*—the crudeness of the name of the institution reflected the then backward state of psychiatry. In that paper Ferrier expressed his thanks to the medical director for placing at his disposal the liberal resources of the laboratory in which he had done his work. Sixty-one years later Mr. Trotter found himself in one respect following in Ferrier's footsteps, in expressing thanks for the help accorded him to that same distinguished physician, now Sir James Crichton-Browne. He was informed by Sir James that, although not himself present at Godlee's operation, he was acquainted with the case both before and after it, and was well qualified by his familiarity with the patient's native place to test his memory. Sir James was the author of a letter in the *Times* which pointed out the direct dependence of the operation upon the results of animal experiment, and which led to some controversy.

"We have been engaged," said Mr. Trotter, "in recalling one of the victories of the human spirit over chaos, and as we take leave of the battlefield we may note that, as in other famous victories, the disposition of forces is not exactly what we might have supposed. The operation involved three great principles—the antiseptic system, the precise projection of the cerebral markings on the surface of the skull as a preliminary to operation, and the doctrine of exact localization of cerebral function. Two of these have long been abandoned by the surgeon, and I should be sorry to define the present position of the third. Nevertheless, each has left a substantial legacy in which the invigorating influence of surgical neurology remains perennial. Thus, though we might hesitate to fight a similar battle to-day under the guidance of these champions, we may yet believe that the event we commemorate is a world event, and worthy of our respectful celebration."

A vote of thanks to Mr. Wilfred Trotter was moved by Dr. ROBERT HUTCHINSON, president of the Royal Society of Medicine, who expressed appreciation of an address marked by philosophical insight, humour, and literary charm.

COMMEMORATION DINNER

A company of over one hundred and fifty attended a commemoration dinner, which was held on the same evening at the Dorchester Hotel, Park Lane, under the chairmanship of Lord HORDER. Among the many distinguished people present the outstanding figure was the veteran Sir James Crichton-Browne, whose ninety-fourth birthday occurred this week, and who was the sole survivor of those concerned with the operation which those present had met to celebrate. Each guest was provided with a facsimile of the *Lancet* page on which a description of the operation was printed fifty years ago.

After the toasts of the King, the Queen, the Prince of Wales, and other members of the Royal Family had been proposed by the chairman and duly honoured, Dr. WILFRED HARRIS proposed the toast of "The Memory of Sir Rickman Godlee," which was drunk in silence.

Dr. Harris recalled that Sir Rickman was a nephew of Lord Lister, and had early become imbued by the principles of antiseptic surgery introduced by his uncle. The operation which he performed had demonstrated that the human brain was no pulpy indeterminate mass outside all surgical intervention, but an organ of definite localizable functions and amenable to operation like other parts of the body. Cancer of the brain was a disease previously believed to be hopeless from the start: it was now a very different proposition.

Sir JAMES CRICHTON-BROWNE, whose delivery was exceptionally striking and virile, responded to the toast. He said that Sir Rickman Godlee's operation had opened up new vistas of hopefulness to those hitherto doomed to misery and darkness. He himself had determined at the time that such an epochal event should not be buried in the pages of the medical journals, and it was he who, under the anonymity of "F.R.S.," had written a letter about it to the *Times*. The result had been a tremendous controversy, which had evoked sixty-four letters and two brilliant leading articles in support of the scientific position. This controversy had raged for three months, and he could scarcely recall any non-political discussion in the *Times* which had attracted so much attention. A number of distinguished men had taken part in it, and, despite the bitter attacks of the anti-vivisectionists, the new brain surgery had made its way. The medical profession was quick to realize that many previously obscure brain lesions could be diagnosed with precision, and that under strict aseptic precautions the brain was not inviolable. While on this subject the speaker referred to an operation recently performed by Dandy in America in which the whole of one cerebral hemisphere had been removed. He added, amidst laughter, that such procedures suggested that the brain was a rudimentary and superfluous organ. From an apt quotation from Shakespeare Sir James passed to a consideration of the thousands of lives which were nowadays saved as a result of the removal of cerebral tumours, and the thousands of men and women who were saved from suffering and disability. He understood that the mortality had been reduced from 100 to 12 per cent. Despite the dubious probings of the psychologists, however, we had not advanced towards a solution of the workings of the mind.

Sir CHARLES BALLANCE, who also responded, said that he had been asked to say something of the surgery of sixty years ago. He traced the history of brain surgery, and paid a special tribute to the experiments of Ferrier and Lister, which had made possible the performance of Sir Rickman's original operation.

The toast of "The Hospital for Epilepsy and Paralysis" was proposed by Lord Horder, who gave an interesting and humorous account of the development of neurology and brain surgery.

Dr. ANTHONY FEILING, who replied, described the growth of the hospital and its present needs, and paid a tribute to Hughes Bennett, who diagnosed the tumour for which Sir Rickman Godlee operated.

Mr. H. W. BURLEIGH, the secretary of the hospital, made a popular speech, while Professor LANGDON BROWNE proposed the toast of "The Chairman," to which Lord HORDER briefly replied.

RESEARCH ON ASTHMA

The annual "Report of Progress" of the Asthma Research Council for the current year¹ summarizes the work which has been done in the various hospital clinics up to October 31st, 1934. In a foreword the chairman, Lord Greenway, notes a year of substantial progress, and states that the patients who attend the clinics are receiving treatment which, though it does not often cure them, almost invariably gives a measure of relief. It is announced that subscribers are being presented this year with a pamphlet on physical exercises for asthmatics; also that a summary of the research work done under the auspices of the Council since 1927, and written by Sir Humphry Rolleston, is shortly to be circulated.

At Guy's Hospital an analysis of 500 case histories by Dr. L. J. Witts has emphasized that the most striking difference between the asthmatic and the normal person is the high incidence of protein hypersensitivity and the frequency of upper and lower respiratory lesions in the former. The value of skin tests has been strengthened by the experimental work of Dr. R. S. Bruce Pearson, which has incidentally demonstrated the superiority of the intradermal over the scratch technique. It is interesting to note here that positive reactions are not infrequently found in normal people and that in asthma the results of treatment fail to exert any appreciable effect on the skin tests. Dr. Bray affirms that, judging from skin tests, the majority of asthmatics are sensitive in varying degrees to several proteins which they are constantly breathing. These include house dust, feathers, orris root, pollens, horse and other animal hairs. Courses of inoculation of oily and watery solutions of these substances plus adrenaline have given very favourable results in reactors, especially with the former and in the predominantly nasal cases, while attempts have also been made to desensitize patients by inhalation methods. As regards hay fever, it is in future intended to treat patients against factors other than those connected with pollen. Other subjects studied during the year have included food allergy and the psychological approach to asthma. The latter shows that the level of intelligence in asthmatic children is superior to that in normal children, and, further, that asthma tends to occur among those who are over-protected and fussed by their parents. Finally, the assessment of results from the various treatments is being continued by Drs. E. T. Conybeare and L. J. Witts, and it has emerged that the general tendency of those patients seeking medical advice is towards improvement irrespective of the treatment prescribed. The general impression gained from the work at Guy's seems to be that protein hypersensitiveness and respiratory damage are the stimuli which make manifest a biochemical difference between the asthmatic and the normal, a difference which should be susceptible of simple treatment.

At St. Mary's Hospital increasing use has been made of a vaccine in which the organisms are such as have withstood the bactericidal action of the patient's blood against which they have been tested. In hay fever injection of large doses of grass-pollen extract has continued to give relief in nearly 100 per cent. of cases. Skin-test control is used, the criterion of desensitization being a negative skin reaction.

The Clinic at Leeds General Infirmary records continued satisfactory results in asthma from non-specific desensitization with liver extract. Campolon or hepatex is administered intramuscularly with an initial dose of 0.5 c.cm., increased to a maximal of 5 c.cm.

At King's College, London, Dr. D'Silva has continued his studies on adrenaline, which, as stated in the previous report, has been shown to cause a large increase in the blood potassium of animals. It is thought that this great release of potassium is not without significance in the relief of asthma by adrenaline, though the administration of potassium salts by Dr. Moll of Leeds has apparently failed to produce the clinical results which might have been anticipated.

¹ Copies obtainable gratis from the Secretary, Asthma Research Council, c/o King's College, Strand, W.C.2.

At the Charterhouse Clinic Dr. Gilbert Scott has been investigating "wide-field" x-ray therapy in asthma. Small doses of medium-wave-length x rays irradiating the whole body, but excluding the thorax, are used, and though a number of successful cases have been recorded, lack of a method of controlling the dosage has always been felt. By means of serological examinations before and after treatment it is thought that a selection of the best type of case can more easily be made. At present the non-infective allergic case responds most satisfactorily.

The Asthma Research Council emphasizes its dependence upon voluntary contributions for the continuation of the work so far carried out.

IMPERIAL CANCER RESEARCH FUND

ANNUAL MEETING

A meeting of the general committee of the Imperial Cancer Research Fund was held at 8, Queen Square, Bloomsbury, on November 22nd, under the presidency of the DUKE OF BEDFORD.

Sir HUMPHRY ROLLESTON, chairman of the executive committee, in moving the adoption of the thirty-second annual report of the Fund for the year 1933-4, remarked that the subjects dealt with were highly technical, and ranged over the whole field of cancer research: pathological anatomy and clinical behaviour, cellular structure, carcinogenesis, and radiotherapeutics. The papers summarized by the director in the eleventh scientific report published with the annual report would no doubt receive attention by specialists in due course.

TRIBUTE TO THE DIRECTOR

In the course of an appreciation of the work of the director, Dr. J. A. Murray, F.R.S., who will retire from that post in November, 1935, Sir Humphry Rolleston said that Dr. Murray's connexion with the Imperial Cancer Research Fund dated from 1903, when the laboratory accommodation was very modest. Together with Dr. E. F. Bashford he laid the foundation for the experimental investigation of cancer by proving that cancer was not confined to man, but was a disease to which all vertebrate animals were subject, and that it presented the same essential features in all the different species. The discovery of Professor Jensen of Copenhagen was at once applied to the study of cancer in animals so extensively and so successfully that within a few years research institutes for the experimental investigation of cancer were being organized all over the world.

"The material collected by Dr. Bashford and Dr. Murray in those early years on the natural incidence of cancer in mice has provided investigators with a knowledge of the disease in that species equal to that in man. It enabled Dr. Murray subsequently to demonstrate the hereditary factor in the incidence of the disease. His study of the early stages of the process of transplantation confirmed the findings of Jensen, and established the important fact that the experimental transmission of the disease represented actually a transplantation of living cells, and was not due to an infection of the new host by some agent separable from the cells. Peyton Rous's subsequent discovery of tumours of the fowl which can be transmitted without the intervention of living cells has led to numerous reinvestigations of Dr. Murray's early work, which have served only to confirm it. Of equal importance are his investigations on the phenomenon of immunity, which renders a normal animal resistant against the transmission of the disease by transplantation.

"In 1915 Dr. Murray was appointed director of the Fund, and as soon as the war was over he began an investigation into the claims made by Professor Yamagiwa and his colleagues that cancer of the skin could be produced experimentally by the repeated and prolonged application of tar to the skin. As a result of this work Dr. Murray was the first observer in this country to verify the statement and to study the development of malignancy in all its phases.

"Dr. Murray's extensive knowledge of the biology and morphology of the cancer cell has been of the greatest value in enabling him to criticize the numerous spurious claims which have been made concerning the cause or the cures of the disease, and thus to protect not only the public but also the medical profession. He has always placed not only the animal material of the laboratory, but also his knowledge and shrewd judgement, at the disposal of his medical and scientific colleagues, and his advice has been much sought after by other investigators.

"During his directorship Dr. Murray has maintained the tradition of the Fund for sound, patient, and careful work which this institution has enjoyed since its inception, and which has given it a leading place among the numerous institutions devoted to the study of cancer throughout the world."

The motion was seconded by Professor W. BULLOCH, F.R.S., and was carried unanimously.

WORK OF THE FUND

The PRESIDENT, from the chair, moved that the best thanks of the meeting be given to the chairman and members of the executive committee, the subcommittees, the honorary treasurer, and others. He said that in the early days of its existence the Fund was practically the only institution carrying out cancer research work on experimental lines, but now there were many other bodies, not only doing similar work, but also appealing for money to carry on their work. It was therefore only natural that the financial support of the public should be divided among all of them. He would, however, like to repeat the statement contained in the treasurer's report for the year explaining the difference between this Fund and other institutions: "It was founded as a research centre to be entirely independent of hospitals or medical schools, with its own laboratory and a permanent staff of scientific investigators engaged solely into research into the causes, prevention, and cure of cancer." It was the only institution of its kind in this country. It began in two rooms placed at its disposal by the Royal College of Physicians and the Royal College of Surgeons. Its staff numbered two, with one or two technical assistants. Now the Fund had a permanent staff of seven scientific men, each skilled in his own particular branch of the investigations, and a technical staff of seventeen; the premises had been enlarged to two floors of the Examination Hall, and in addition a farm and laboratory at Mill Hill. Even these premises were no longer adequate for all the work that was being done. The director and his staff were frequently consulted by other investigators, both scientific and clinical, and the Fund had, from the very beginning, been particularly careful to protect the public against misleading claims of alleged cures for cancer by its careful investigation of all the claims submitted to it. Though progress might seem to the lay mind to be excessively slow, much knowledge of importance had been gained of the nature and treatment of the disease. As in other problems of medicine, patient research would ultimately reap its reward in the cancer problem, and the Duke of Bedford expressed the hope that the public would continue to support generously the work being done in the laboratories of the Fund. In conclusion, he endorsed the tribute already paid to the director, Dr. Murray, for the excellent service he had given during the past twenty years as director of the Fund.

Sir John Rose Bradford, Professor W. Bulloch, and Professor A. E. Boycott were re-elected members of the executive committee. Professor E. H. Kettle was elected a member of the general and executive committees, and Professor E. Mellanby, secretary of the Medical Research Council, a member of the executive committee. The meeting closed with a warm vote of thanks to the Duke of Bedford for his presence in the chair and his great interest in the success of the Fund.

Reference to the annual report of the Fund and the director's scientific report for the past year will be made in an early issue.

Scotland

Finlayson Memorial Lecture

The history of the prevention of malaria formed the subject of the Finlayson Memorial Lecture delivered to the Faculty of Physicians and Surgeons in Glasgow on November 19th by Sir Malcolm Watson, director of the Ross Institute in the London School of Hygiene. The lecturer said that work in Malaya had proved that when malaria was removed the number of deaths from other diseases was also reduced; this showed the lowering effect of malaria on the general health of a people in allowing other infections to establish themselves. In 1904 the Malay Government had undertaken anti-malarial work on fifty square miles of intensely malarial swampy land with complete success. On the estates of one company no case of malaria in a European had been contracted since 1912, and during the last five years the admissions for this disease among the labourers had been 0.1 per cent. It had been realized in 1909 that malaria in hill land presented a special problem, since it was due to a mosquito that lived in running water. Success had been obtained by putting streams and springs in underground pipes, and in certain parts of the country by preserving jungle or swamp or growing shade, an opposite method to that which was required to combat malaria on low-lying flat land swamps. During researches on the biology of various forms of mosquito it had been found possible to control species by altering the chemical composition of water, and this had now become a recognized procedure in different parts of the world. By raising or lowering the salinity of water dangerous mosquitos had been eliminated in places as far apart as Java, Albania, and Holland, and malaria had been driven out by these slight chemical changes. Through this discovery great engineering works, such as the Singapore waterworks, the Perak hydro-electric company's dam, the naval base at Singapore, and the great Zambesi bridge had been undertaken, with almost no loss of life from disease, instead of a death rate of 200 per 1,000 with great delay in construction and greatly increased cost. The speaker had calculated that by 1920 Ross's discovery regarding the transmission of malaria had been instrumental in saving about 100,000 lives in Malaya. In Singapore anti-malarial work was begun in 1911, and there was reason to believe that over 100,000 lives had been saved by sanitary methods in that city alone. A great work had been done at Havana and Panama by the American Government; in India research on Malayan lines had been undertaken since 1924, and the Ross Institute had created a great organization to assist the tea and other industries. The health of both Europeans and Africans in Northern Rhodesia had been improved; the death rate among Europeans had fallen from 23 per 1,000 in 1929 to 5 per 1,000 in 1933, and that among African natives from 30.9 in 1930 to 5.2 in 1933. In the work on the Zambesi bridge, just completed, only two Europeans had fallen ill from malaria, and these had contracted the disease away from the site of the bridge; yet this area had been one of the most unhealthy in the world.

Extension of National Health Insurance

The memorandum of evidence submitted by the Scottish Association of Insurance Committees to the Departmental Committee on Scottish Health Services, which has now been published, emphasizes the demand for extension of the national health insurance scheme to dependants of insured persons. It is pointed out that the worker is greatly handicapped by a scheme which entitles him alone to treatment, while illness among his dependants must

be treated either by the public assistance medical officer or must result in bills which he has difficulty in meeting. It is also insisted that in any general scheme the family should for medical purposes be treated as the unit. There are now fifty-four insurance committees, including thirty-one county and twenty-three borough committees, and these deal with about 1,873,000 insured persons. Of the latter about 44 per cent. are resident in Glasgow and the three contiguous counties. Of the total number at the beginning of the present year, 1,757,000 insured persons were members of approved societies, 16,500 were deposit contributors, 3,500 were exempted persons, and 153,000 came within special classes, such as married women and persons over 65. The cost of administering medical benefit amounted to £50,000 per annum, or about 6d. per insured person. Chemists to the number of 1,632 with 1,837 shops were under contract with the Scottish insurance committees, while the number of practitioners under agreement with them was 2,039. In the majority of areas every general practitioner was on the panel list, although in larger towns some were not. The number of insured persons whom a doctor might have on his list was limited to 2,500, but certain committees reduced the figure to 2,000, and in some instances to 1,500. About two-thirds of the doctors in county areas had under 500 persons on their lists, while in the boroughs only one-third of the doctors had fewer than 500. The report expresses the opinion that medical benefit under the Insurance Act has been amply justified. A much-needed extension, however, would be the inclusion for health purposes of young people from the date of leaving school to the age of 16, and expert and specialist medical advice and treatment should be provided as well as laboratory services.

Retirement of Dr. R. B. Campbell

At the last quarterly meeting of the Joint Committee of Stirling District Mental Hospital intimation was received of the resignation of Dr. Robert B. Campbell, F.R.C.P. Ed., from the post of medical superintendent. Dr. Campbell was appointed medical superintendent of the Inverness District Mental Hospital in 1904, after having held posts as assistant superintendent at Montrose Royal Asylum and the Crichton Royal Asylum, Dumfries. He took up his duties at Stirling in 1908. In 1932 he was elected president of the Royal Medico-Psychological Association of Great Britain, and is now chairman of the Scottish Asylum Pathological Scheme. It was decided to defer taking steps to appoint a successor until the beginning of next year.

Diphtheria Immunization

The Public Health Department of Edinburgh is inviting practitioners to co-operate in an attempt to undertake the immunization of all children in the city below the age of 5. It is pointed out that during the last ten years the average annual incidence of diphtheria in Edinburgh was 781 cases, and the average number of deaths forty-seven. An attempt has been made to reduce this incidence by carrying out diphtheria immunization in schools. Each child when it first began school was given a consent form and an informative leaflet to take home to its parents. When consent was granted the children were given three injections of 1 c.cm. of diphtheria toxoid at fortnightly intervals. Further, a certain number of children under school age were brought by their parents for immunization, but there was no doubt that the vast majority of children of the pre-school age group had not yet received the benefit of protective inoculation. Seeing that the disease was most prevalent and most fatal in this pre-school period, it was essential that an effort should be made to immunize as many as possible. It is now

proposed that diphtheria toxoid should be provided free of charge to practitioners willing to immunize in their private practice children over 1 and under 5 years, and that a fee of 7s. 6d. per child should be paid on intimation to the health department that the requisite injections have been completed. Supplies of formol-toxoid are obtainable in 1 c.cm. ampoules from the Public Health Department, Johnston Terrace, Edinburgh.

Appointment to Metropolitan Police College

The authorities at Scotland Yard have decided to institute a scientific laboratory at the Metropolitan Police College at Hendon, and have appointed Dr. James Davidson as its head. Dr. Davidson graduated M.B., Ch.B., at Edinburgh University in 1920. During the war he served in the medical branch of the Royal Navy, and after graduation acted for a period as resident physician in Edinburgh Royal Infirmary, and later was appointed assistant pathologist to the institution. Subsequently he was appointed lecturer in morbid anatomy in the University of Edinburgh, with charge of the post-mortem department in the Royal Infirmary. He has made numerous contributions to problems dealing with the scientific aspects of medicine and pathology:

England and Wales

Classification of Inmates in Public Institutions

The London County Council has been considering the classification of the inmates of its public institutions. At present the public assistance institutions contain a number of public health cases, and vice versa. Differences in terminology and in classification of inmates have been inherited from the boards of guardians; thus persons classified in one union as infirm would in another fall into the category of chronic sick. "Able-bodied" has in some cases meant all who were able to attend the dining hall for meals; in others only those fit for work. It has been decided that inmates or patients to whom the primary approach should be medical (that is, those who should be seen, examined, and supervised by the medical officer without request by the inmate or by an attendant) should be under the control of the Hospitals and Medical Services Committee, and those who were in need of assistance because of destitution, and did not fall within the former category, should be under the control of the Public Assistance Committee.

The following categories of inmates or patients will therefore fall under the control of the Public Assistance Committee: (1) able-bodied (that is, persons physically capable of work); (2) healthy (that is, able to look after themselves, including healthy aged, healthy deformed, healthy feeble-minded, and expectant and nursing mothers); (3) infirm (that is, persons requiring a certain amount of assistance in dressing or moving from room to room, and who may require in bad weather to spend a few days in bed); (4) healthy children of 3 years or over, pending transfer to schools; and (5) healthy infants, except infants separated from their parents. The following categories will be placed under the control of the Hospitals and Medical Services Committee: (1) chronic sick (that is, persons suffering from any specific disease necessitating their confinement wholly or practically wholly to bed, also extremely aged persons confined to bed on account of extreme weakness); (2) mental cases; (3) maternity cases; (4) sick children; and (5) sick infants and healthy infants separated from their parents. The most important consideration is: What are the primary needs of the classes under consideration? The first need of the infirm class is

suitable accommodation, though individuals may need medical care from time to time. On the other hand, for the chronic sick and for persons whose conditions of health may vary considerably in the course of the year, medical care and nursing are the primary requisite, and suitable accommodation an adjunct thereto.

At the end of last winter there were about 4,700 public assistance cases being cared for in public health institutions, and about 1,600 public health cases in public assistance institutions, so that reclassification implies an ultimate net increase of about 3,000 beds in the accommodation under the management of the Public Assistance Committee. As from December 1st, admissions by relieving officers' orders of chronic sick cases will be to public health establishments, and of able-bodied, healthy, and infirm cases to public assistance institutions. Hitherto, cases admitted on such orders have been sent to the institution which formerly belonged to the parish or union in which they reside, without reference to the question whether it is the appropriate institution under the scheme of classification.

Health and Cleanliness

Next year will see the centenary of local government, a fact which lends particular interest to the sixth annual luncheon of the Health and Cleanliness Council, held at the Holborn Restaurant on November 21st, with the president, Dr. G. F. Buchan, in the chair. More than 160 people, representing local health, education, and insurance committees, schools, health societies and other organizations connected with national health, and the Press, were present. In proposing the toast of the Health and Cleanliness Council, Dr. James Fenton, chairman of the Central Council for Health Education, said that one hundred years ago this country was without even the rudiments of a public health service. The nation's wealth and property were protected, but the nation's health was nobody's concern. But in 1834 there were increasing signs of a change in the national consciousness regarding this important subject, which culminated in the Public Health Act of 1875. This Act was an important milestone, and up to 1900 resulted in almost miraculous changes, including adequate provision for proper drainage and scavenging, removal of house refuse, provision of fever hospitals, and a satisfactory water supply. In 1900 Great Britain stood head and shoulders above all nations in the matter of public health services. Still greater progress was made in the first quarter of this century; maternity and child welfare centres were established, and tuberculosis services reduced the death rate from this disease by 50 per cent. But in spite of all these services we were not yet getting the best results. The working classes did not yet fully appreciate the services provided for their benefit. It was still essential to teach the people that what was good enough for their grandparents was not good enough to-day. It was precisely here that the Health and Cleanliness Council could do, and did, its best work. It came into existence primarily to assist the local authorities in this educative work. Dr. Fenton reminded his audience that the council was in close touch with 120 health authorities, seventy-seven education authorities, thirty-nine insurance committees, and thirty other similar organizations. He complimented Miss Norah March, the enthusiastic secretary; Dr. Buchan, the president; and Professor Kennell. In reply Dr. Buchan referred to the lasting truth of the council's slogan—"Cleanliness is the first law of health." He would like to go much further, and advocate universal public baths, public wash-houses, and private baths. There had been a change, he said, in the habits of the people. They desired cleanliness; they desired the open air life and more recreation. Even the housewife, most hard-working of women, was lifting up her voice to demand more leisure. Labour-saving devices, of which

electricity was the most important agent, were coming to her rescue. He himself hoped that we were approaching the time when all labour-saving domestic appliances would be available to all classes and all purses. Houses were now being built with this principle well to the fore. Already there were a greater number of houses where the housewife was considered in so far as they were easier to keep clean than the older type of house.

West Riding Medical Salaries

The report of the Public Assistance Committee of the County Council of the West Riding of Yorkshire for the year ended March 31st, 1934, contains an important reference to the salaries of district medical officers transferred from the former boards of guardians. From the date of its appointment, it is stated, the committee recognized that the pre-transfer rates of salaries were in a large number of instances disproportionate to the duties and responsibilities, and were not founded upon any uniform basis. Careful consideration was given to the matter from time to time; during the year under review recommendations were made to the county council with reference to dealing with such cases, and adjustments in salary and terms of remuneration were made. In addition, the Public Assistance Committee has varied the terms of appointment of district medical officers to provide that the supply of drugs and medicines shall no longer be the responsibility of the medical officers concerned out of the inclusive salaries paid to them for their professional services. An arrangement has been made under which these drugs and medicines prescribed by them for the outdoor poor shall be dispensed by a panel of chemists throughout the West Riding administrative area, and be paid for separately by the county council. Consideration has been similarly given to the question of holidays, since these were found to have lacked uniformity in the past, and a scale has been drawn up. Medical officers, hospital assistant matrons, ward sisters, and charge nurses are now to receive the equivalent of eighteen working days, while probationer nurses receive twelve. Accommodation in some institutions has been certified by the Board of Control, and eighty-six beds are reserved for mental defectives at three such, the West Riding Mental Deficiency Act Committee being responsible for these patients. Relief of a special character was granted in 717 cases, of which ninety-four were in respect of dentures and 150 of surgical appliances. Arrangements have been made for verification of the family circumstances, and for recovery of the expenses when reasonable. Restrictions upon public expenditure have continued to affect the progress which it had been hoped to attain in the development, modernization, and reconstruction of institutional accommodation, but a good deal has been done, nevertheless, by way of improvement and repair in cases of urgency.

The Waking Hour in Hospital

On the question of patients' waking hours King Edward's Hospital Fund reports further progress by the London voluntary hospitals as the result of its recommendation that, unless there was some exceptional and adequate reason to the contrary, the most suitable hour for the waking of patients was 6 o'clock. This recommendation resulted from an inquiry held in 1931.¹ At that time the hour of waking was earlier than 6 o'clock at 53 per cent. of the London hospitals. By 1932 the number had fallen to 31 per cent., and it has now been further reduced to 21 per cent. Calculated as a percentage of the number of patients the results are still more satisfactory, only 15 per cent. of the total number being

awakened at an earlier hour than 6 o'clock. All the hospitals which continue to have an earlier hour than 6 o'clock give some special reason for it; and the visitors of the King's Fund will be asked to report on these reasons at the next annual inspection of these hospitals.

Maudsley Hospital Courses

Lectures and practical courses of instruction for a diploma in psychological medicine will commence at the Maudsley Hospital on January 1st, 1935. Part I of the course will include twelve lectures on the physiology of the nervous system and four lectures and demonstrations on physiological psychology by Dr. F. Golla; four lectures on biochemistry in relation to the nervous system by Dr. S. A. Mann; eight lectures on the anatomy of the nervous system by Professor Le Gros Clark; eight lectures on applied psychology by Dr. Henry Devine; six lectures on mental mechanisms by Dr. E. Mapother; eight lectures on contemporary schools of psychology by Professor F. A. P. Aveling, and two on the practical application of intelligence tests by Dr. F. C. Shrubbsall. Part II of the course will open in March. The fee for the whole course, Parts I and II, is £15 15s.; for Part I or II separately £10 10s.; for single series of lectures in Part I £4 4s. or in Part II £2 2s.; for single series of demonstrations £1 1s. Inquiries should be addressed to Dr. F. Golla, honorary director of the Medical School, Maudsley Hospital, Denmark Hill, S.E.5.

Reports of Societies

ANTE-NATAL CARE AND THE MATERNAL DEATH RATE

The Sections of Epidemiology and of Obstetrics and Gynaecology of the Royal Society of Medicine combined for a discussion, on November 23rd, on "The Results of Ante-natal Care: How they can be Improved." Dr. J. D. ROLLESTON presided, and such interest was taken in the discussion, about twenty speakers participating, that the meeting was prolonged beyond the customary two hours.

Dr. ISABELLA CAMERON, medical officer of the Ministry of Health, said that she had been one of the students of Dr. Ballantyne, the pioneer of ante-natal supervision, who approached it from a study of foetal pathology, but saw in it a neglected branch of midwifery. His teaching was an inspiration in early days to workers interested in infant welfare rather than to his fellow obstetricians, and consequently ante-natal work tended at one time to be a subsidiary activity of the organizations for infant care. The majority of expectant mothers had now some degree of ante-natal supervision, which was inadequately associated with attendance at confinement and during the lying-in period. Ante-natal care was too frequently regarded as an entity apart from the midwifery service. No single part of that service was in complete alignment with any other part, and too little recognition was given to the fact that, biologically, pregnancy, labour, and lying-in were consecutive phases of one process. Much ante-natal visiting lacked direction and precision, and many consultations were conducted in a perfunctory and half-hearted manner. Some of the officers were not only junior in status, but inexperienced in dealing with patients. Ante-natal work became to too great an extent an eager search for the abnormal, and opportunities for the support and encouragement of women passing through a normal pregnancy were lost.

IS THE MATERNAL DEATH RATE REALLY HIGH?

Mr. G. F. GIBBERD (Guy's Hospital) said that it was useless to regard ante-natal care as a separate part of midwifery. An improvement in the practice of ante-natal care would come about as a part of the improvement in the practice of midwifery as a whole. Maternal

¹ *British Medical Journal*, June 6th, 1931, p. 982.

Dr. W. H. F. OXLEY spoke as a general practitioner who had for many years carried out ante-natal, intra-natal, and post-natal work. He was absolutely convinced that there was a great deal of good in ante-natal care, but ante-natal care represented perhaps only 5 per cent. of midwifery practice as a whole. Midwifery had crept from the general practitioner. Thirty years ago, in advertisements of practices in the *British Medical Journal* it was made a selling point that there were "250 midwifery cases a year"; but now it was the other way about—the bait was "no midwifery." Nevertheless, where a general practitioner took an interest in the subject and had working in close touch with him a competent body of midwives and a general hospital, he could get results second to none. As for Professor Browne's scheme, it looked nice on paper, but was quite impracticable.

Dr. LETITIA FAIRFIELD said that ante-natal work had been "over boosted," and there was now a reaction.

The maternal mortality rate, as Mr. Gibberd had said, was really low, and its further reduction was influenced by the law of diminishing returns. Two critical factors in midwifery were the technique in the conduct of the normal case and the employment of a consultant who would be on the spot and watch an abnormal case throughout. Professor Browne's scheme was interesting, but she thought it likely to be so expensive that no ratepayer in the country would be able to afford to have a baby.

Dame LOUISE McILROY said that failure in ante-natal work was due to want of continuity in observation. One of the openers in the discussion had spent his time pointing out the errors of the specialist, which was very easy. That was the bane of the position: that those concerned all became critics of one another. She agreed that the general practitioner knew more about the patient herself than anybody else, and if he could be attracted into the service he would be the one who should undertake the work. She suggested a panel of general practitioners, all of whom would have had post-graduate training in maternity hospitals. Undergraduate teaching in this subject was still open to a good deal of criticism.

ANTE-NATAL CLINICS AT FAULT

Dr. G. W. THEOBALD said that just as it was a tragedy that anaesthesia should have been discovered thirty years before antiseptics, the result being to inflict suffering on thousands of people who would not otherwise have suffered, so it was unfortunate that just when the public conscience was becoming aroused over maternal mortality the cult of the ante-natal clinic should develop. If every ante-natal clinic in this country were swept away the mortality would not be increased; it might be lowered. On analysing the causes of deaths of mothers, a certain number were found to have died from diseases associated with pregnancy; these would not be affected much by ante-natal care, though ante-natal beds might be a different story. As for the toxæmias of pregnancy, there was not the slightest evidence that ante-natal care could affect the death rate. Ante-natal care was not a substitute for good midwifery, and it made an enormous amount of needless midwifery possible. He was convinced that maternal mortality could be reduced by half within the next ten years, and with less expenditure on the maternity service, if there were established about sixty hospitals on the Rotunda principle, each working a certain radius by means of midwives and general practitioners, and all abnormal cases being sent into hospital. As for Dr. Oxley, he declared himself a general practitioner, but he was in reality an obstetric specialist, and the speaker would rather see the hospitals he had suggested staffed with practitioners of Dr. Oxley's type than "with F.R.C.S.'s galore with no experience."

Dr. F. N. REYNOLDS suggested that if Government departments had analyses showing in what branch of the service—midwives, hospitals, general practitioners, specialists—the major mortality occurred, these should be placed before the Section of Obstetrics for discussion so that respective responsibility could be assessed. Mr. L. C. RIVETT declared obstetrics to be a whole-time job, demanding much patience and very irregular hours. A whole-time service was the only solution of the difficulty, and the same obstetrician who conducted the confinement should supervise ante-natal and post-natal care. Dr. W. M. FELDMAN agreed that x-ray examinations were of enormous value. He also agreed with the statement that deaths from septic poisoning were not entirely due to exogenous introduction of toxin, but possibly to endogenous toxic states.

NO GROUND FOR PESSIMISM

Professor JAMES YOUNG was disappointed at the pessimism of the discussion. They were all apt to be discouraged at the slow response to the energy expended on this problem, but the Maternal Mortality Committee laid down some very simple propositions, and he was convinced that if they were put into operation alleviation would come about. It had to be borne in mind that the maternal death rate was a compound of very varying

figures. In some districts it was 2 per 1,000; in some it went up to 10 or 12. Surely in the present state of knowledge 12 should be regarded as an excessive figure, which it should be practicable greatly to reduce. One town in the North of England, by simple measures, had brought down its average from nearly 9 per 1,000 to 1.7.

Mr. ALECK BOURNE referred to the great importance of teaching the technique of normal labour. Patients were lost from errors in handling midwifery and the too early use of forceps. The ante-natal officer was inclined to be too much haunted with the fear of disproportion. If ante-natal work were done by people more experienced in normal labour there would be less interventions and more spontaneous labours, and therefore a lower death rate. Lady BARRETT considered the two most urgent matters to be the education of the medical student and greater access by the general practitioner to practical work and experience by way of refresher courses. Dr. DICK REID said that one of the greatest dangers of obstetrics was the academic mind, and one of the greatest sources of help to proper ante-natal care of women would be the naturalist mind applying the philosophy of development to the study of the natural functions of woman. Sir WELDON DALRYMPLE-CHAMPNEYS mentioned that once it was his duty to organize a reply to a questionnaire from the British Medical Association on the general subject, and at the meeting at which the nature of the reply was debated one general practitioner got up and stated that he always applied forceps unless there was a strong contraindication. Dr. MARY KEENE urged the desirability of the universal provision of milk for pregnant women and nursing mothers.

All the openers briefly replied. Professor BROWNE said that his scheme had received exactly as much support as he had expected, which was none at all. Dr. Oxley had declared it to be impracticable; he would be only too delighted to offer Dr. Oxley the first directorship in his county unit. Dr. Fairfield had said the scheme was too costly. But it would cost only two millions, and the British Medical Association scheme would cost two millions and a quarter. Cheap midwifery would not give the results.

BRITISH ORTHOPAEDIC ASSOCIATION

The annual meeting of the British Orthopaedic Association was held in London on November 2nd and 3rd. Clinical programmes were arranged at St. Bartholomew's Hospital by Mr. R. C. ELMSLIE and his colleagues, and at the Lambeth Hospital by Mr. G. F. STEBBING. The Robert Jones gold medals were presented to Mr. R. W. BUTLER and Mr. H. J. SEDDON, whose essays on the subject of Pott's paraplegia were read in opening the first discussion.

Pott's Paraplegia

Mr. R. W. BUTLER said that in tuberculous disease of the spine three clinical types of paraplegia should be differentiated. The first type, "early onset of temporary paraplegia," was due to toxic and vascular reactions in the cord from the activity of tuberculous disease, and sometimes to compression of the cord by caseous granulation tissue. In the second type, "early onset of permanent paraplegia," the paralysis persisted after recovery of the tuberculous disease owing to avascular atrophy of the cord; it was attributable to prolonged compression of the cord by abscesses, to acute thrombosis of the vessels supplying the cord, to bony compression by pathological dislocation of the spine, or to compression by the displacement of sequestra. In the third type, "late onset of paraplegia," the paralysis might appear many years after apparent quiescence of the disease, and this type included 50 per cent. of the whole series of 193 cases. Late paraplegia was due to atrophy of a previously damaged cord as a result of prolonged or of fresh infection; bony compression was a rare cause, and there was no evidence that chronic tuberculous meningitis was responsible for paraplegia at any stage.

Mr. H. J. SEDDON said that for every four cases of early onset of paraplegia which recovered there was one which failed to recover. Failure was due either to persistence

of cord compression for too long a period or to the sudden complications of vascular thrombosis or bony compression by dislocation. Treatment, therefore, was primarily conservative, and included immobilization and hyperextension. If some voluntary power remained the prognosis was excellent, but if there was complete loss of voluntary power recovery was improbable unless pressure was relieved during the first six months. If there was not spontaneous recovery within six months of onset costotransversectomy and evacuation of the abscess was indicated. When the onset of paraplegia was sudden, and paralysis was complete within a few days, bony compression should be suspected, and relieved by hyperextension of the spine. Laminectomy was only indicated in cases exhibiting the spinal tumour syndrome (the neurological signs preceding the orthopaedic sign), or in cases of posterior spinal disease. Cases of late onset of paraplegia should be treated conservatively, but in severe cases the removal of tuberculous material or of bony ridges, and combined laminectomy and spinal grafting, should be considered. If there was complete motor paralysis for more than six months there was no likelihood of recovery. The subject was covered so fully by the very admirable opening papers that the time available for further discussion was strictly limited. Mr. G. R. GIRDLESTONE (Oxford) pleaded for the relief of pressure by costotransversectomy at an even earlier stage, and Mr. McCRAE AITKEN said that the pressure could be effectively relieved, without actually removing bone, by dissecting between two transverse processes.

Transport of Cases with Back Injuries

Mr. T. P. McMURRAY (Liverpool) said that in fractures of the spine the advantage of face-down transportation was that the postural movement necessary to reduce the fracture was instituted at once, so that the risk of injury to the spinal cord was minimized. The disadvantages were such that patients suffered from shock and that lying on the face might embarrass respiration; there might be fractures of several ribs with danger of visceral injury. The speaker did not advocate any change in the existing teaching; first-aid workers could not be expected to diagnose fractures of the spine, and the act of turning patients over was dangerous.

Mr. McMurray's recommendation was supported by Mr. P. B. ROTH. It was opposed by Mr. Watson Jones, Mr. McKenzie Crooks, Professor Houghton, Mr. Clarke, Mr. Davidson, and Mr. Hope Carlton.

Mr. R. WATSON JONES (Liverpool) said that St. John Ambulance men were already taught to turn these patients over, but they were instructed to turn them on to their backs and to lift them by a method which inevitably produced hyperflexion. If a patient with a fracture-dislocation was carried in this manner severance of the cord was inevitable. The association of rib and spinal fractures was so rare as to be negligible, and in any event the ribs were no more likely to be fractured in front than behind. Professor HOUGHTON (Dublin) said that the diagnosis should not give rise to difficulty. If, after a severe injury, a conscious patient complained of pain in the back and inability to move one or both legs he should be lifted and carried face downwards. Mr. MCKENZIE CROOKS (Nottingham) reported a series of fifty cases of spinal injury; there was only one case with injuries to the ribs, and that patient was more comfortable on the face than on the back. Mr. H. O. CLARKE (Manchester) said there could be no doubt that ordinary face-up lifting was capable of producing paraplegia which did not previously exist. The speaker had personally witnessed a throw from a horse which caused fracture of the spine without paraplegia; the patient was turned and lifted by ambulance men and was paraplegic by the time hospital was reached. Death resulted from bladder infection.

Congenital Club-foot

Miss FORRESTER-BROWN (Bath) advocated repeated manipulation, splints, and plaster as the routine treatment for congenital club-foot, but said that many cases relapsed despite every care and attention. Open division of the tight structures on the inner side and at the back

of the heel was often necessary, and in old cases an astragalectomy was sometimes performed. A rotation osteotomy of the tibia was a valuable procedure for persistent in-toeing.

Mr. B. L. McFARLAND (Liverpool) said that open operations on the inner side of the foot were followed by scar tissue contracture, and sometimes the deformity relapsed. Tenotomy of the tendo Achillis was rarely indicated, and was a dangerous procedure. Mr. C. LAMBRINUDI advocated early tenotomy of the tibialis anticus and posticus, but these procedures were condemned by Mr. NAUGHTON DUNN (Birmingham), who said that division of the anterior tibial tendon caused claw-foot, and division of the posterior tibial tendon caused flat-foot. Mr. E. P. BROCKMAN considered astragalectomy to be a very bad operation, and said that all cases so treated relapsed sooner or later. The speaker recommended open division of the tight structures on the inner side of the foot.

Fractures of the Neck of the Femur and Intra-articular Arthrodesis of the Hip

Mr. WATSON JONES said that after high fracture of the neck of the femur there was often radiographic evidence of impairment of blood supply in the proximal fragment, and this accounted for the slow union of these fractures. Nevertheless, the neck distal to the fracture had a normal blood supply, and its decalcification and absorption was due to the traumatic hyperaemia of continued movement of the fragments on each other; it was not observed when the fracture was perfectly immobilized. The prolonged and complete immobilization necessary could be secured by the Smith-Petersen nail, but the operation was most difficult. The speaker had devised a canalized nail and guide to facilitate accurate central insertion by open operation. A similar principle had been independently used by West in Australia and Sven Johansen in Sweden, but these workers had developed a subcutaneous technique with Kirschner wire and radiographic control which was more difficult and less certain. The treatment was relatively safe even in very old people, because no splints or plaster were used; no weight-bearing was permitted until the fracture was united. The operation was contra-indicated in old fractures with avascularity of the head of the femur. Non-union after arthrodesis of the osteoarthritic hip was analogous to non-union after fracture of the neck of the femur and could be prevented in the same way by driving a Smith-Petersen nail into the pelvis. With this addition to the technique of simple intra-articular arthrodesis consolidation was certain and rapid.

Mr. E. W. HEY GROVES (Bristol) had seen the Sven Johansen technique on the Continent; two or three hours of tedious work had been involved, and the speaker believed that the open operation which had been described would prove more satisfactory. Mr. NAUGHTON DUNN (Birmingham) said that the operation was one of great difficulty, even in the hands of Smith-Petersen himself, but the high percentage of successful results reported commended the method. Mr. V. H. ELLIS advocated earlier weight-bearing in a walking calliper splint, but the opener replied that the Thomas splint or calliper was dangerous in such high fractures, and was not to be recommended at any stage of treatment; the splint extended up to but not beyond the fracture, and directly transmitted every movement of the limb to the level of injury.

Movement of the Lumbar Spine and Pregnancy

Mr. LAMBRINUDI reported clinical observations which disproved current obstetrical teaching that lumbar lordosis was normal in pregnancy. Normally there was extension of the lumbar spine and flattening of the sacrum, but this movement was only possible if the muscular tone was good, and the sacro-iliac and lumbo-sacral joints were mobile. Failure in this mechanism, with the development of abnormal lumbar lordosis, accounted for backache during and after pregnancy. Mr. N. CAPENER showed comparative series of radiographs of the lumbar spine with patient lying, standing, and stooping. The intervertebral foramina were enlarged in flexion of the spine and narrowed in hyperextension. The bearing of this observation on scoliosis was discussed.

Adolescent Coxa Vara

Mr. V. H. ELLIS, reported nine cases of slipped upper femoral epiphysis, and advocated gradual correction of the deformity by skeletal traction in a Thomas splint. Forcible correction by manipulation under anaesthesia usually caused degeneration of the epiphysis and osteoarthritis of the hip. Mr. E. N. WARDLE (Liverpool) advocated traction in the neutral or even the adducted position by means of a Thomas frame, with the groin strap on the affected side.

OPERATION MASKS

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Academy of Medicine in Ireland, held on November 9th, with Dr. BETHEL SOLOMONS in the chair, Professor R. E. TOTTENHAM showed operation masks, designed by himself, which he considered more efficacious in a tropical climate than the masks used at home. They were smaller and made of lighter material, so the operator, when wearing them, did not get too hot.

Dr. SOLOMONS said that the small celluloid mouth mask seemed to be a practical proposition. For some time he had been using, in gynaecological surgery, a mask with a piece of cellophane between the layers of gauze. It had been proved to be unnecessary to cover the nose unless the operator had a cold. It would be worth while conducting the experiment of talking over agar plates with the celluloid mask on to ascertain if it were effective.

Dr. J. F. CUNNINGHAM thought that the operation masks shown by Professor Tottenham were a great improvement on those in current use. He referred to a Viennese mask, which he had recently seen, and which fitted a little bit lower on the face than those shown by Professor Tottenham, and did not obstruct vision at all. A mask which did not come over the nose must be very much cooler than one which did. In America they had made several efforts to invent a perforated mask constructed from an impervious material.

Cervical Myoma

Dr. D. J. CANNON showed specimens from a patient with associated cervical and broad ligament fibroids.

Dr. SOLOMONS said that while he did not agree that the treatment of cervical myoma could be absolutely standardized certain rules could be laid down: (1) In most cases the ureter should be defined in its pelvic course. (2) While myomectomy was often possible, in case of any doubt about haemostasis hysterectomy should be done. He suggested that the technique of finding the settling time of the blood was so simple that it should be done in all cases of possible infection. Broad ligament myoma was not the correct term to apply to the cervical tumour.

Dr. CUNNINGHAM said that these types of fibroids were rather uncommon, and generally gave rise to a great deal of difficulty in removal. When he removed them he always preferred to carry out extracapsular removal. He thought that if this was done it was easier to control the haemorrhage. The most troublesome bleeding occurred from veins. He mentioned a case in which he had removed a fibroid and got a certain amount of haemorrhage from the side of the uterus. He tied the vessels on that side, and the patient did very well; eighteen months later she was delivered of a healthy baby. The main difficulty in these cases was to control the blood supply, and, if it was possible to get to the base of the uterus, it was not very difficult to do this. He was of opinion that it was always easier to control the haemorrhage from these tumours if they were taken out of their capsules. He thought it was practically impossible to standardize treatment in such cases.

Dr. F. S. BOURKE asked if the specimens were really broad ligament fibroids. He thought that they were not; he regarded them as uterine myomata which had grown into the broad ligament. Cervical fibroids were often adenomyomatous, and not just ordinary fibroids such as were found in the uterus.

CORRESPONDENCE

Elections to G.M.C.

SIR,—I should be much obliged if you will allow me through your columns to thank those registered medical practitioners of England and Wales who, in the recent election to the General Medical Council, expressed by their votes a renewal of their confidence in me as their Direct Representative.—I am, etc.,

London, N.W.11, Nov. 26th. HENRY B. BRACKENBURY.

Radiological Practice

SIR,—The time has surely come when steps should be taken to prevent the use of x-ray apparatus by those whose capabilities are inadequate. The present legal position is that anyone may purchase and use equipment which is, as is well known, a potential source of danger both to patient and to operator. Thus it is possible for any individual to employ x rays for diagnostic and therapeutic purposes without having the necessary anatomical, pathological, and medical knowledge. Can it be right that a radiographer (however skilled he may be as a technical worker), a chemist, or an engineer should be legally empowered to express an opinion as to the evidence of a pathological process or to expose a patient to a beam of x rays for purpose of treatment. It is, of course, recognized that members of the Society of Radiographers undertake that they will not interpret radiographs, and that they will not carry out radiation therapy except under the strict supervision of a qualified medical practitioner; but there are many quasi-radiographers who are not members of this society, and who, therefore, are *not* bound by such an undertaking.

Radiographic interpretation and the determination of x-ray dosage call for very skilled judgement, but it is suggested that such is not among the attributes of many who succumb to incautiously phrased advertisements, which infer that efficient radiological practice requires nothing more than the acquisition and operation of a piece of apparatus.

The remedy appears to lie in the hands of the general members of the medical profession. The assistance afforded to them by radiology may be immense, but only when they will recognize that the whole subject is one requiring endless study, subsequent to a thorough training in general medicine, with especial reference to pathology and physics.—We are, etc.,

G. SHEARER,
President, British Institute of
Radiology.

J. DUNCAN WHITE,
Chairman, Medical Committee, British
Institute of Radiology.

Short-wave Diathermy

SIR,—May I sound a note of warning with regard to the so-called short-wave diathermy therapy—ultra-high-frequency—or by whatever other name this treatment is called.

The time is not yet ripe to discuss in a general medical journal the differences between treatment by this method and treatment by ordinary diathermy. Also clinical experience is still limited, and opinions must necessarily be tentative. The point, however, that I do wish to make is that in this newish technique we have a treatment capable of sometimes altering a patient's symptoms rapidly, even occasionally dramatically, and therefore

it is to be regretted that there is a tendency to write it up as a new panacea. It is nothing of the kind.

The dangers in this position are threefold: first, that it may go through a false boom like ultra-violet light; secondly (again like light) serious harm may be done to a few; and thirdly, the genuine group of cases for which it would be the treatment of choice will be lost sight of. The discussion at the Royal Society of Medicine on November 16th on this subject, opened by Dr. Turrell, was interesting in disclosing widely divergent views. The only way in which sound clinical judgement can be formed is by the gradual accumulation of a mass of clinical results, both in hospital and in private practice, by medical practitioners familiar with the scope and reaction of its better-known cousin—diathermy. Do not let us ruin a new, and possibly valuable, therapeutic measure by exaggerated claims.—I am, etc.,

London, W.1, Nov. 26th.

C. B. HEALD.

Influence of Heat and Light on the Nasal Mucosa

SIR,—In regard to the annotation on this subject in the *Journal* of November 24th (p. 951) I would point out that Winslow, Greenburg, and Herrington, just as Dufton and Bedford, did not carry out my experimental method, but one so arranged that it could not yield the results obtained by me. They left one nostril open for breathing, while connecting the other by a well-fitting tube to a recording instrument.

Now if a glass tube, one inch long, be chosen large enough to fit comfortably the open nostril, the lower opening of this tube can be greatly narrowed (even till its area is only one-sixth of that of the upper opening) without significantly affecting the quiet breathing of a resting subject. This method is, then, much too insensitive.

The spirometer method used by Winslow and his co-workers was arranged so that results due to nasal congestion produced by the source of heat were recorded. But no precaution was taken to see if this source was of such a strength that the "nose-opening" rays had a chance of showing their effect. There is, as I have pointed out, a balance between the actions of the rays, and this must be found by experiment. My critics do not appear to have paid any attention to this important point. "Nose-opening" rays can easily be shown by the following method.

An electric heating coil, about 4 by 1½ inches, is set up in a stand, and beside it is placed a small solid tungsten rod arc. The coil, heated to a dull red, gives off about fourteen times more energy than the arc. The subject sits about two feet from, and facing, these two sources, which are, at the start, screened from him. A screw nose-clip (obtainable from Messrs. Siebe Gorman, Ltd.) is adjusted to the subject's nose, and tightened until the respiration becomes slightly difficult; the right adjustment of the nose-clip is most important. A corrugated rubber tube (such as is used for breathing apparatus) is fastened round the body of the subject; one end of this is closed, and the other connected to a recording tambour, which is set to write on a slow-moving drum.

The subject keeps the eyes shut, or is blindfolded. A record of breathing is now obtained; then the screen is removed, and the two sources allowed to irradiate the subject's face. The breathing continues unchanged. The arc is next screened; the breathing in most subjects then becomes laboured, or quick and shallow; in many the mouth has to be opened, as nasal breathing becomes ineffectual. On unscreening the arc the breathing returns to what it was before. For subjects who have a considerable constriction of the nasal airway the use of the nose-clip may not be necessary.

My critics have tested one or two such subjects, but they apparently paid no attention to the need of using a source of heat of such strength that the "nose-opening" rays from the bright source had a chance of exerting their effect.

When the method described above is carried out some subjects will be found insensitive to the action of "nose-closing," and therefore of "nose-opening" rays. In the case of most of the sensitive subjects a glass screen converts the sun, or an arc, used alone, into a nose-closing source.

I have taken records from many members of the staff and patients of the St. John Clinic and Institute of Physical Medicine; some of these will shortly be published.—I am, etc.,

London, S.W., Nov. 25th.

LEONARD HILL.

X-Ray Examination of Empyema Cavities

SIR,—Observation of over one hundred cases of chronic empyema at the Brompton Hospital during the past two years suggests to me that the views expressed in Dr. A. Duff's letter in the *Journal* of November 17th (p. 921) are most dangerous.

The only reliable indication for discontinuing drainage of an empyema cavity is that there should be no longer a cavity to drain. The evil results of removing the tube before the cavity is obliterated are often not immediately apparent. The sinus usually heals, and the surgeon congratulates himself on an "impressively quick cure." I do not deny that in many cases he may be right. But the most careful clinical and radiological examination will not inform him of the probable future behaviour of an unobliterated pleural pocket. If this is left, it fills with discharge and its walls thicken and temporarily protect the patient from toxic absorption. Then, months or years later, this pocket may burst either externally or into a bronchus. Such recrudescence has been seen here as long as fourteen years after the original empyema. If it points externally a chronic persistent or recurrent discharging sinus results. If a pleuro-bronchial fistula forms, the resulting syndrome resembles that of *letid* bronchiectasis, and we occasionally have such cases sent here with this diagnosis. The chronic empyema cavity, the obliteration of which is necessary for cure, is by this time lined with grossly thickened and leathery pleura. I need not stress the great difficulty of dealing with such a condition: a series of severe and extensive operations is often required, involving disability for many months.

By maintaining adequate and proper drainage of acute empyemata until it is clearly established, if necessary by x-ray examination after introduction of lipiodol, that the cavity is obliterated, the incidence of chronic empyemata after uncomplicated acute empyemata can be reduced to zero.—I am, etc.,

Brompton Hospital.

London, S.W.3, Nov. 19th.

Plea for Abolition of the Pelvimeter

SIR,—In his letter on this subject Mr. Aleck Bourne is, presumably, being deliberately provocative, and has for that reason not hesitated to strain his argument. Experiences differ, and it is certainly not my experience that Caesarean sections or inductions of premature labour are performed on the basis of external pelvimetry alone. Mr. Bourne will not deny that if the external measurements (even allowing for the possible inaccuracies of which it makes the very most) are definitely below normal they suggest that the true pelvis is also smaller than normal.

and that if the average difference between the interspinous and intercrural diameters is markedly altered it suggests that the shape of the true pelvis is also altered. Such suggestions of abnormality in regard to the true pelvis are surely all that is derived from external pelvimetry by anyone with any knowledge of midwifery. If that is so, then, I submit, their value is considerable, because they determine a particularly careful estimation of the size and shape of the true pelvis, as well as of the relative size of the pelvic brim and the head.

Performed by an experienced obstetrician, digital examination of the pelvis, as preferred by Mr. Bourne, may be most helpful; but when he relies upon the "knuckle test" of the inter-tuberischial diameter he seems to me to fall into the very error he condemns. To "measure" by an instrument of variable size—that is to say, by a variable standard of measurement—cannot be put forward as an accurate method.

Mr. Bourne's questions are as difficult to answer as the much-discussed "peace questionnaire." The only one to which I could give an unqualified "Yes" is the last, and it is not really germane to Mr. Bourne's main point.

As another of your correspondents states, we seem to be on the verge of another "drive" in connexion with maternal mortality and morbidity. The last one induced a condition bordering on national hysteria and panic, and led to hasty administrative measures whose results have been disappointing. In the opinion of many this misfortune was the result of following extreme opinions. Mr. Bourne's advice seems to me to be an "extreme" measure of over-correction of a fault that is less common in my experience than in his. I put it to him that what he really wants is not that we should discard our pelvimeters, but merely that we should not exaggerate the significance to be placed on external pelvimetry. In that view I am sure that he will have the support of all obstetric teachers.—I am, etc.,

Edinburgh, Nov. 26th.

R. W. JOHNSTONE.

SIR,—Mr. Aleck Bourne's letter pleading for the abolition of the pelvimeter, in view of the increasing death rate, in spite of our ante-natal methods, is deserving of support. Both external and internal pelvimetry are unreliable and harmful; accurate measurements cannot be made, and the patient is subjected unnecessarily to injury and sepsis. The same objection can be made to internal pelvic examination with the finger; besides, the employment of this method in a young woman necessitates an anaesthetic if discomfort or actual pain to the patient is to be avoided.

The most accurate method, as I pointed out in 1923 (Portsmouth meeting), of diagnosing the capacity of the pelvis and measuring the size of the inlet and outlet is by the x rays. Roentgenographic pelvimetry, besides demonstrating pelvic deformities, the effect of old fractures, or diseased joints, makes it possible not only to see the existence and extent of the pelvic contraction, both at the inlet and outlet, but also to compare the abnormal with the normal pelvis and measure the degree of contraction.

Every woman should have her pelvis measured by the x ray to see if she is fitted for child-bearing, and towards the end of her pregnancy, according to the degree of her contraction, if any abnormality is noted, another photograph should be taken to ascertain the presentation of the child and its size relative to that of the pelvis, thereby giving a definite diagnosis, and enabling the case to be treated by a suitable method.

If every woman on her first visit to the ante-natal clinic had her pelvis x-rayed it could be compared and measured with the "standard" photograph, and once

and for all that woman would have a certificate of her pelvic capacity, which she could keep for future reference. No matter to what part of the world or to what doctor she went, she could, if the necessity arose, give accurate measurements of her pelvis, and save unnecessary examination, with its accompanying risks to sepsis.—I am, etc.,

Belfast, Nov. 26th.

W. R. MACKENZIE.

SIR,—I venture to express my delight at seeing Mr. Aleck Bourne's reference, in the *British Medical Journal* of November 24th (p. 963), to the uselessness of external pelvimetry. By openly stating his belief Mr. Bourne has had the courage to express an obstetrical reality of considerable importance. Unfortunately he proceeds to state an unreality when he mentions the frequency with which induction of labour is followed by inertia. The subject is one to which I have devoted considerable time and attention with very ample material.

Uterine inertia (a very real clinical entity) has never yet harmed an infant, nor has it ever been responsible for maternal damage or morbidity if correctly treated. Surely the condition to which Mr. Bourne refers is in reality incoordinate uterine action, spastic in character, and capable of passing into a condition of uterine "panic" if oxytocics are given or instrumentation applied.

If Mr. Bourne doubts me, let him ask the sister in charge of his wards the next time one of these cases to which he refers comes under his care. I venture to prophesy that in answer to his query as to whether Mrs. X is having any pains, he will get the reply, "Not real pains, Mr. Bourne." This answer is the sister's only means of conveying the reality of incoordinate uterine action, in the present state of textbook teaching.—I am, etc.,

WENTWORTH TAYLOR.

Dudley Road Hospital, Birmingham,
Nov. 24th.

Anaesthesia in Maternity Cases

SIR,—This subject has so constantly been written about that I think the experience of an old country practitioner may be of use.

During over forty years' general practice I, in the later periods, almost invariably administered an anaesthetic. Sometimes the patient would use the apparatus herself, but more frequently the nurse, or it would be given by myself. The apparatus I used was one made by Krohne and Sesemann of London. It consists of a graduated bottle, to be hung from the practitioner's or nurse's clothes, and two tubes, one conveying the chloroform to the mask, and the other terminating in a rubber pump. The bottle was filled to the two-drachm mark and the first inhalations were given very weak. I often utilized this by giving the patient the pump to use herself; when she became more or less unconscious the flow of the anaesthetic naturally failed. The secret of success consists in the very small amount given at first, and, indeed, the design of this apparatus is to prevent the possibility of administering much at a time: I have kept a lady under the anaesthetic for four hours, giving great relief from pain for most of the period, and at the end pumping a little faster, and so entirely relieving all pain. In one case the husband, who desired to be present, gave the anaesthetic himself all the time (four hours).

I have used this apparatus in many operations. In one I remember a Doubting Thomas saw the bottle filled to the two-drachm mark, and when the femoral hernia operation was completed he again examined the reservoir, and found I had only used 30 minims of chloroform, while the patient neither moved nor experienced any pain during the operation. In alcoholic subjects it is notorious that larger

quantities of the drug must be used, but in all cases I began with the treatment I have stated; it is safe and satisfactory.

The danger in administering chloroform is in giving strong doses at first. One should begin with two or three minims in the first minute, *very gradually* increasing each minute. There should be no choking or coughing nor any distress whatever, and a couple of drachms of the drug would relieve over a considerable period if given *intermittently*—a few whiffs when the pain shows evidence of coming on, and perhaps a remission during the interval. Given in this way the patient can converse and yet receive great relief from pain.

I would like to add, in view of the apparent increase in the number of fatal confinements, that in a matter of 2,000 cases I had but two deaths. Neither of them had I attended at the birth; one I was called to about half an hour before she died. There was no uterine trouble to account for it, but I learnt that she had had hardly any sleep for a fortnight previous to delivery and during the day was doing cheese-making and caring for a number of children; she simply died of exhaustion. The other death was due to an embolism carried to the heart during an attack of white leg, when the patient sat up in bed contrary to orders.

For years I used copiously a thymol ointment, and very seldom found any feverish conditions following the birth; I consider thymol one of the most valuable antiseptics.—I am, etc.,

Peatchaven, Nov. 19th.

ARTHUR CAMPBELL.

Dilating the Cervix in Placenta Praevia

SIR,—Whatever Dr. Bethel Solomons writes is of course worthy of the utmost respect. All the same, I venture to think myself not quite so "horribly" heterodox as might appear. I do regard over a score of cases as constituting a considerable experience, especially so since all save two of them were dealt with single-handed, and all in country cottage homes.

From the sixteenth century onwards dilatation and version were taught by Paré, Guillemeau, Mauriceau, Smellie, and others. Smellie says: "In all these cases let the parts be dilated slowly, and by intervals, to prevent laceration." On this Robert Lee says (1842), "These are the most clear, concise, and accurate rules which have been laid down by any author." Herman says (1897 ed., p. 311): "Dilatation of the cervix has formed a part of almost every plan of treatment that has been proposed. It is usually necessary, because dilatation of the cervix must precede delivery." And Comyns Berkeley (1925 ed., p. 502): "In all cases in which the os is half or more dilated, it will be quite easy to dilate it further so as to allow the performance of internal version." I sin in excellent company. There were brave men before Agamemnon, and I like the old dictum that fingers were made before forks—to wit, dilating bags.—I am, etc.,

Harston, Cambridge, Nov. 24th

W. J. YOUNG.

Spontaneous Regression of Cancer

SIR,—Unlike Cervantes's hero, our modern Don Quixotes no doubt have an eye to news value when tilting at windmills. Your editorial comment on Dr. A. T. Todd's letter makes it so clear that he has deliberately chosen to misinterpret my remarks that he is not entitled to any reply from me. In case, however, there should be any shadow of doubt as to the calculated nature of his preposterous attack, I will quote from my letter to him dated November 9th, 1933 (a copy of which I enclose):

"I think you misunderstood what I said in reference to the spontaneous cure of cancer. My words were: 'It is only fair to state, too, that there are records—some highly circumstantial—of nearly 400 cases of complete spontaneous cure of cancer.'"

"My implication was, therefore, that if there are so many cases which are claimed as being spontaneous cures it suggests that in such cases a long period may elapse during which the patient appears to be cured. I do not believe for one moment that they are in fact cured, and I suggested elsewhere: 'So far as I am concerned I have never known a single case of idiopathic regression or apparent arrest of tumour growth in which eventual recurrence did not manifest itself.'"

"My whole attitude, however, is that one must be extremely cautious in respect to the view that any particular method of treating cancer is efficacious unless one bears in mind the natural variations in the course of the disease and waits a great many years before arriving at definite conclusions."

If Dr. Todd wishes to be taken seriously he will cease to imply that even 400 *fully authenticated* cases of spontaneous cure can affect materially the gravity of the cancer problem. Bashford calculated that spontaneous regression occurs in one case among 100,000. Does such a percentage destroy the necessity for cancer hospitals or cancer research, as Dr. Todd with flippant hyperbole suggests?

It should also be known to Dr. Todd that, largely at my instigation, his methods of treating malignant disease are to be given an exhaustive and thorough trial at the Cancer Hospital. This scarcely argues the prejudice which his egregious letter would imply.—I am, etc.,

London, W.1, Nov. 26th.

Cecil A. Jell.

Female "Bleeders"

SIR,—I was interested in the reports and comments on female bleeders, by M. A. Foulis and J. W. Crawford (*British Medical Journal*, September 29th, 1934), W. N. Leak (*ibid.*, October 13th), and Robert Platt, Hugh G. Garland, and L. Ivan M. Castleden (*ibid.*, October 20th). Before one may accept the reported instances of female "bleeders" as examples of true hereditary haemophilia, other haemorrhagic dyscrasias must be considered in the differential diagnosis (H. I. Goldstein, *Medical Review of Reviews*, New York, 1934, xi, 471; *Archives of Dermatology and Syphilology*, 1932, xxvi, 282; *International Clinics*, 1934, ii, Series 44, p. 43).

We must particularly consider thrombocytopenic and athrombopenic purpura, and *apurpura* thrombocytopenic and thrombasthenic conditions, heredo-familial angiotaxis with recurring haemorrhages (Rendu-Osler-Weber's disease), Willebrand and Jürgens's *Die Konstitutionelle Thrombopathie*, and Hess and Glanzmann's thrombasthenia, as well as "haemorrhagiparous haemotrypsin" (Emile-Weil, Chevallier, Clerc and Levy), and Opitz and Frei's "pseudohaemophilia ex afibrinogenia" (1921). Bramwell (1907) reported, erroneously, as "haemophilia" instances of severe epistaxis in a family in which the disease was transmitted, chiefly through the male line.

A fairly large number (about 120 families and about 850 affected individuals) of cases of heredo-familial epistaxis, with and without angiotaxis (Goldstein), have been reported in the literature during the past forty years. This condition has nothing whatever to do with true hereditary haemophilia, familial purpura haemorrhagica, or (Riverius, Lusitanus) *Werthof's purpura haemorrhagica*. This condition was first separated from true haemophilia by Rendu (1896) of Paris, who considered it "pseudo-haemophilia."

A number of instances of female haemophilia are on record in the literature. Bullrich and Fildes (1911) mention

¹ Long Fox Lecture, 1933.

a number of such cases, collected by them in an exhaustive study of the literature. True cases of haemophilia in females (supposedly) have been reported by Tamme Beth (1829), Lafargue (1835), Kuhl (1836), Quadrat (1841), and were so considered by Grandidier (1855). Lange (1849) also speaks of female haemophiliacs, and found the ratio of female to male bleeders was 1:7; Grandidier considered the ratio to be 1:14. Among others who discussed the subject of female "bleeders" were: F. A. Kehler (1876), E. Börner (1878), Immermann (1876, 1879), R. Kolster (1895), Wright, Böhm (1909), Rieken (1829), Mende (1839), Wachsmuth (1849), J. Tamele (Prague, 1869), Cantani (1872), Börner (1878), Eve and Bidwell (1839), Gocht. (1899), Beebe (1891), M. Fischer (1889), H. Fischer, Burger, Wright, Gustavo Pittaluga (Madrid, 1902), P. Stanley Blaker (1901), and others reported instances of female haemophilia, but Bulloch and Fildes, after their exhaustive studies, do not believe these instances to be examples of true haemophilia. Wm. Bulloch published his article on "Female Haemophiliacs and De Novo Cases of Haemophilia" (*Lancet*, i, 1900) in 1910.

Cases of familial epistaxis have been reported by many authors: Sir W. Fordyce (1784), P. J. Schneider (Offenburg, 1839), H. Jameson (1831), F. Steiner (1842), Wilhelm von Bippen (1842), Richard (1830), Georges, Boye (*Thèse de Paris*, 1910), William Osler (*Lancet*, 1910, i, 1226), Ed. Stainer (1910), Smith (1867), Lohmeyer (1832), P. St. Using (1833), E. Gintrac (1853) (doubtful instances of familial epistaxis in two brothers, one died at 24, "of cerebral congestion"), J. W. Legg (1871), Lepeyre, C. L. (*Thèse de Paris*, 1875), H. Hertzka (1881), S. Keneagy (1884), Beebe (1891), Macnamara (1884), P. Albertoni (1893), Masters (1900), Villemain (1900), D. McKenzie (1901), J. Dommartin (1903), P. Ste. Marie (1904), Godfrey (1905), Goodall (1905), B. Bramwell (1907), R. B. Davidson (1907), A. J. Swanton (1907), H. Althoff (1909), L. Frankel and L. Böhm (1909), A. Lombardi (1909), G. Cohen (1890), and numerous others. Some of these instances of "familial epistaxis" may, of course, be considered of doubtful haemophilic origin, and others may be instances of Rendu-Osler-Weber's disease (with or without evident telangiectases), thrombasthenia, or constitutional thrombopathy.

—I am, etc.,

HYMAN I. GOLDSTEIN, M.D.

Camden, New Jersey, U.S.A., Nov. 1st.

Septum Cauterization in Asthma

SIR,—Dr. George W. Bray, in the second edition of his book, *Recent Advances in Allergy*, says: "Cauterization of the nasal septum has been advised by Francis during the past thirty years. The idea of the cauterization is to dull the receptive area in the nose, where irritative stimuli may lead to the naso-pulmonary reflex already described" (that is, bronchospasm).

I should not ask you to allow me to correct this misconception if Dr. Bray's book was not such an authoritative and standard work, and if I did not feel that the misconception was likely to retard the investigation of the successful treatment of asthma. For thirty-two years I have been doing my utmost in published papers and books to emphasize the fact that ordinary cauterization is likely to do more harm than good to the asthmatic condition. It is unfortunate that I have to use a caution point to produce the effect I seek upon the vasomotor system.

In 1910 I stated (*Journal*, November 26th): "The merest touch which causes no local irritation or reaction is the one which produces the best result. I feel that I ought to sound a note of warning against indiscriminate nasal cauterization. When one sees the profound and diverse effects a touch with the cautery can produce upon the vasomotor system, it is necessary to proceed with caution and with some knowledge of what the effect is likely to be." In 1933 I stated (*Asthma and its Treatment*): "I cannot emphasize too strongly the fact that my method of treatment is not simply a matter of nasal cauterization. For the last thirty years I have been

constantly asked why I attempt to treat a healthy nose. It seems impossible to make it understood that I am not treating the nose. . . . In cases where there is hypersensitiveness of the nasal mucous membrane the prognosis is not so good."

Earlier in his book Dr. Bray says (p. 105): "In Francis's view asthma is merely a symptom of vasomotor instability. . . . He has tried to show how the touching of certain points on the nasal septum was in some way connected with the stabilization of the vasomotor system." If practitioners could only realize that nasal treatment does not rely upon removing asthmogenic spots from the nose, but upon producing a stabilizing effect upon the vasomotor system, much progress would be made in giving relief to the asthmatic condition, and damage from indiscriminate cauterization avoided.—I am, etc.,

London, W.1, Nov. 15th.

ALEXANDER FRANCIS.

Swallowing of Open Safety-pins

SIR,—I was very much interested in Mr. Courtenay Yorke's suggestions (*Journal*, November 3rd, p. 811) for the treatment of cases in which open safety-pins had been swallowed. I must confess that I believe it to be the safer course to remove the pin from the stomach before it has passed into the intestine than to risk the danger of perforation. The following case is probably unique.

On the evening of August 26th, 1934, a male child, aged 8 months, swallowed an open safety-pin. An oesophagoscopy was carried out soon afterwards by Mr. R. J. Martin, but he found that the pin had passed into the stomach—this was confirmed by x rays. The child came under my care some hours later at the Birkenhead and Wirral Children's Hospital, and it was decided to remove the pin the following morning from the stomach. An x-ray was taken, but it was seen that the pin had moved on into the duodenum.

In view of its inaccessibility in this region it was thought wise to defer operation. During the next few days the pin slowly moved down to the right iliac fossa, where it stuck. Laparotomy was therefore undertaken. After a search of the lower reaches of the ileum, the ileo-caecal valve, and the caecum, the appendix was carefully palpated, and to my surprise the pin was found lodged in the tip with no sign of perforation. The appendix was removed, and the child made an uneventful recovery.

Subsequently an x-ray was taken of the appendix with the pin *in situ* (see figure).—I am, etc.,

Liverpool, Nov. 14th.

PHILIP HAWE.

Local Treatment of Coryza

SIR,—Mr. W. C. Spackman, in the *Journal* of November 3rd (p. 835), raises the issue of local treatment of coryza in connexion with the theory "that a general infection is less dangerous if its local reaction is severe." These are not his exact words, but I understand this to be his meaning.

The two propositions are not quite identical, because the coryza is not a general infection, say, like septicaemia, but a local one, which, when it is truly inflammatory in character, will produce systemic and general symptoms, the latter being the manifestations of invasion by what may be regarded as an intranasal inoculation. His letter has provoked some very interesting contributions. Dr. Douglas Webster (November 10th, p. 882) gives a list of

remedies which he has found effective, and the merits of many of which I believe to be based upon sound principles. Dr. R. R. Woods (November 17th, p. 920) goes, in my opinion, to the root of the question when he emphasizes the importance of the changes occurring in the nose as inflammatory phenomena, due to microbic invasion, and (in the sense which I interpret him) asks what are the biological defences of the body aiming at, so far as we understand them to-day. In health we are familiar with purposeful vaso-dilatory swings when certain functions of the body demand more blood, as, for instance, the splanchnic contrasted with the cutaneous areas during the process of digestion.

In disease of an inflammatory character there is a pronounced vaso-dilatory swing (with other additional factors, too long to detail here), and when this disturbing cause is severe many of the physiological demands on vaso-dilatation pass for the time being into abeyance—for example, loss of appetite. In a true coryza, together with the local pain, heat, redness, and swelling, we have the general symptoms of toxic invasion, such as pyrexia, malaise, headache, tachycardia, chilliness (vaso-constriction), constipation (vaso-constriction), etc.

Now while the process of immunity is being developed by *vis medicatrix naturae* the rational line of treatment, as I see it, is to adopt every measure possible to get rid of the toxins, and this is best done by encouraging vaso-dilatation of all the excretory organs of the body—the skin, bowels, kidneys. The time-honoured treatment for the relief of the local symptoms of inflammation is counter-irritation, producing hyperaemia at a distance. This is only vaso-dilatation, and that is why I consider Dr. Douglas Webster's treatment of gargling with hot water, drinking the same, hands and feet in hot water (or our old friend the mustard foot or body bath), hyperaemia by ultra-violet light or diathermy, are all sound in principle and will cut short a mild attack. But if it is severe I would carry this vaso-dilatation a stage further by putting the patient to bed, make him perspire, and give aperients and diuretics; this, together with eliminating his toxins, would lead to the rapid subsidence of his nasal and general symptoms.

I am averse to using any local liquid treatment in the nose in the active stage of acute inflammation, and have stated this view in published articles, because I am convinced that the patient's own protective defences against infection have already mobilized better forces to the spot than any which I can add, with our present knowledge. Inhalations of steam are soothing, and, if thought fit, may be medicated with tinct. benzoin co.; but wearing a light gauze mask, for the greater part of the day and night, will be most comforting, practically stop sneezing and coughing, protect him from further local infection, and protect others, in some measure, from him. In an inflammatory process of the type of coryza which I visualize here many of the epithelial cells are cast off and take some weeks to regenerate, so with this knowledge it is difficult to conceive that any method of treatment can limit its activities to a few hours. There is, however, a common form of non-pyrexial disturbance of ventilation of the nasal passages, accompanied by vaso-dilatation and diagnosed as a cold or coryza because the symptoms of obstruction, sneezing, and discharge occur in sequence; but this is not inflammatory (pyrexia being the test), and the local use of vaso-constrictors, aided by any form of general hyperaemia, will give rapid relief.

That the nose is frequently attacked when the lower respiratory tract escapes is common knowledge, for which we should be truly thankful, because in its role of a respiration outpost and defensive mechanism, for the preparation and purification of air before it goes to the lungs

for the vital process of oxygenation, it is not to be wondered at that it must often succumb to air-borne infection in the conditions of modern life, so long as the human mucous membrane reacts to microbic invasions. Dr. Potter's alkaline treatment (November 17th, p. 921) diminishes this susceptibility, but control of the alkaline reserve for a long period is too complicated, and has its pitfalls.—I am, etc.,

London, W.1, Nov. 19th. JOHN F. O'MALLEY, F.R.C.S.

London University and its Medical Schools

SIR,—Sir Ernest Graham-Little has no doubt done well to draw attention to the lamentably small proportion of medical students who, having embarked upon the London M.B., B.S. course, actually obtain the degree. But I trust that no one will be so unwise as to comment upon Sir Ernest's proposal, outlined in his letter published by you on November 24th, without having something more definite in the way of an explanation of this fact than the vague remark, "the majority of students entering for the London course . . . are unable to stay the course for the third examination."

One would like to know: (1) What is the exact proportion of such students who do pass the whole of the Second M.B.? (2) What proportion of these sit once for the Third M.B.? (3) What proportion of these fail at the first attempt and in what parts? (4) What proportion of those who fail once attempt the examination a second time?

Doubtless these data are known to the Senate of the University. Whether they should be divulged in your columns I leave to the judgement of Sir Ernest. But without them any discussion of the subject, or a possible remedy, appears to me foolish.—I am, etc.,

London, W.1, Nov. 26th.

ERIC PEARCE GOULD.

SIR,—Sir Ernest Graham-Little's letter, in your issue of November 24th, about degrees in London University comes at a time when revision of the medical curriculum is being widely discussed.

The first difficulty in London University arises with the First M.B. examination. I have never been able to understand why this examination is not interchangeable with that for the Intermediate Science. The length of time allotted to both courses is the same, and yet the First M.B. is definitely considered to be of a lower standard.

The First M.B. ought to be the chemistry, physics, zoology, and botany of the Intermediate Science examination. The student who changes his mind would then be able to go on with a Science degree and not have to start again at the beginning as at present.

The Second M.B. is another problem. The minimum course of study for a first degree in London University takes three years. The normal time for the Second M.B. is two and a half years. If this examination was a degree examination the course of study would have to be lengthened by three to six months. Most medical students in this University are poor men, and cannot afford the time. A few are able to spend another year and take the B.Sc. in physiology, chemistry, or human anatomy, but this number is very small.

A degree in Medical Sciences on the lines of the Tripos at Cambridge would undoubtedly encourage students to spend an extra three or six months, and would add to the popularity of the University of London. I have no doubt that the difficulties in arranging this on the lines suggested by Sir Ernest can be overcome.—I am, etc.,

Teddington, Nov. 26th.

E. E. D. GRAY, M.D.

SIR,—May I, as a looker-on, be permitted to make a suggestion in support of Sir E. Graham-Little's kindly proposal for removing a hardship which many London students seriously feel? The injustice is that students who have given proof of being worthy of definite university recognition are shut out from the hope of it, often from financial reasons. An adjustment of standards, so that the affected examinations would both serve their present purpose and also worthily qualify for a degree, would solve the problem, but what name should the degree have? If care be not taken the public, already puzzled over titles, will be more bewildered than ever.

Could not the work for the proposed degree suitably become an optional course for the present B.Sc.? The prestige of the M.B., B.S., following a Science degree, would be thus enhanced. Two universities, Oxford and Dublin, only allow medical graduation to those already B.A., and surely a preliminary B.Sc. would be even more appropriate.—I am, etc.,

Liverpool, Nov. 26th.

GLYNN WHITTLE.

The Toll of War

SIR,—In proposing the toast of "The Common Health" at the Council Dinner, Professor R. J. A. Berry reminded the gathering of the triumphs of preventive medicine. He pointed out (*Supplement*, November 10th, p. 258) that "a century or two ago" every second person present, if he had survived, would probably have been heavily pitted with small-pox. He went on to speak of the diminishing mortality from disease in war. In the American Civil War 1 per cent. of the men died of typhoid, in the American-Spanish War thirty years later the death rate from typhoid had contracted to 0.1 per cent. In the European war it had shrunk to 5 per 100,000 men—0.005 per cent. Professor Berry justly concluded that medical men had every right to be proud of these achievements. Perhaps in the next war not a single soldier will die of typhoid fever!

But, Sir, there is another side to the picture. I do not refer to the fact that, if only five in 100,000 died of typhoid, 99,995 would survive to swell the casualty lists of which Mr. Lloyd George has recently reminded us. There is little difference between being a gas or shell casualty and a case of typhoid.

In the chapter "Demographic Effects of Modern Warfare" of a work published by Victor Gollancz, Ltd. (1933) and based on official statistics of the countries concerned, there are some statements that must deeply interest the medical profession. From the demographic point of view victors and vanquished are on the same plane, and results depend on general conditions and the normal demographic character of the country. There is in all wars profound disturbance of the natural movement of the population and increased civilian mortality from epidemics. While in the world war typhoid was less fatal, typhus invaded Serbia, Russia, Poland, and Austro-Hungary, and influenza overran the world. Influenza was imported into Europe and India by warships and transports, thus reaching the military depots, land armies, and civil population. Great Britain had 200,000 deaths, Germany 400,000, Italy 430,000, and Spain and Portugal 200,000. In a few months in India, according to a Ministry of Health Report,² 8½ millions died.

¹ *What Would Be the Character of a New War?* Pp. 275 et seq. An inquiry organized by the Inter-Parliamentary Union, Geneva.

² Ministry of Health Report on the Pandemic of Influenza 1918-19, London, 1920 (p. 286). "The military censorship forbade the publication of news concerning the progress of the epidemic in the belligerent countries during the war. It was only after the epidemic had invaded the neutral countries, Spain in particular, that the Press was able to speak of it freely. That is probably why it has been given the name of Spanish influenza."

The statistics of typhus, typhoid, cholera, small-pox, dysentery, malaria, plague, and pulmonary tuberculosis show that war is the affair, not of the belligerents alone, but of human beings all the world over, the surplus of deaths in neutral countries in Europe alone in 1914-18 being close on 600,000. Napoleon cynically boasted that one night in Paris would repair the losses of a battle, but nowadays the birth rate is steadily and rapidly falling, while war also so disturbs the balance of the sexes that, just after the war, in France there was a 20 per cent. excess of women between 25 and 30—25 per cent. in Germany.

The volume published by the Inter-Parliamentary Union concludes that the total deaths in the world war caused directly (military) and indirectly (civilian) are 41,435,000—a still incomplete balance sheet, for it does not include the millions of deaths from famine in Russia following the war. To that total the European contribution is 25,000,000, or more than the combined populations of Sweden, Norway, Denmark, Holland, and Switzerland.

Well, as our profession has a special responsibility in the lives of people and their deaths from bullets or from bacteria, there is surely no matter here for congratulation or complacency. I am well aware, Sir, that, as J. B. Priestley says, "it is an old worn topic: the choicer spirits begin to yawn at the sight of it; those of us who are left of that generation are, it seems, rapidly becoming mumbling old bores"; but, I sometimes wonder, is there any more important subject for us to dwell on and come to some conclusion about, or must we stand aside and leave it to others—to Parliament, to the Press, to the "City," to the "Services," to the Church?

"And, Robert Browning, you writer of plays, here's a subject made to your hand," might surely be applied to the medical profession all the world over.—I am, etc.,

Cannes, Nov. 11th.

A. A. WARDEN.

Whither General Practice?

SIR,—There has recently been in the columns of the *Journal* an interesting but rather depressing correspondence on the subject "Whither General Practice?" Unless more constructive efforts than I have observed during the last quarter of a century are made by that large section of the medical profession known as general practitioners, the answer to the question may also be given in three words: "It will wither."

At the present time efforts seem to be concentrated on giving the general practitioner opportunities of following up and attending his patients in hospital. In spite of the considerable difficulties to be overcome before arrangements enabling the general practitioner to do this can be made, this might be the starting-point of considerable medical progress. However, it has always seemed to me regrettable that the British Medical Association, while ready to honour the man and itself by electing him president in its centenary year, has paid such scant attention to the scheme which Lord Dawson first outlined in the Cavendish Lecture which he delivered to the West London Medico-Chirurgical Society soon after the war. In this scheme the primary centre, the centre of first interest to the general practitioner, formed a most important part.

Not having at his disposal all the resources—electro-therapeutic, radiological, pathological—such a centre would provide, the general practitioner is apt to persuade himself he can do very well without them—an impossible assumption at the present time—and is disappointed at finding his patients leaving him to attend the well-equipped hospitals. Something might be done to over-

come these deficiencies of equipment by amalgamations of practitioners in urban districts such as are now so frequent in rural areas, but external help, voluntary or State, would seem to be necessary before a satisfactory system of primary centres could be founded. Such centres would, by ensuring the more satisfactory treatment of disease in its early stage, save the expenditure of much money on buildings necessary for the treatment of disease in its later stages.

Can it be that the interest in the early manifestations of disease aroused by the late Sir James Mackenzie has already died down?—I am, etc.,

London, W.8, Nov. 19th.

HAROLD H. SANGUINETTI.

Ronald Ross and the Panama Canal

SIR,—In the *British Medical Journal* of November 17th (p. 917), Lord Leverhulme is reported as having stated with reference to the Liverpool School of Tropical Medicine: "In the past the School rendered it possible for 40,000 persons to live and work in the region of the Panama Canal, where once 90,000 had perished." Lord Leverhulme has been misinformed. The French abandoned the attempt at constructing the Panama Canal after suffering terrific mortality from both malaria and yellow fever. Subsequently the U.S.A. Government, through Surgeon-General Walter Wyman, head of the American Public Health Department, invited Sir Ronald—then Major—Ross to join the Isthmian Canal Commission. The recommendations proposed by Sir Ronald Ross having been carried out, white men were enabled to live in the region and complete the construction of the canal. Hence it was not due to any medical school but through the genius of one man that the Panama Canal reached completion.

America freely acknowledged her debt of gratitude to Sir Ronald Ross at the time. Most people in Great Britain to this day are ignorant of his achievement. It is at least incumbent on those who (like the writer) had the great privilege of knowing, and studying under, the late Sir Ronald Ross, to salute and honour "the mighty dead." I desire to add that my memory of the Liverpool School of Tropical Medicine is very grateful and very dear.—I am, etc.,

Canterbury, Nov. 21st. J. CHAS. RYAN, D.T.M.Liverp.

Tests for Colour-blindness

SIR,—The Medical Research Council has issued a report on colour-blindness in which it is stated that the apertures of two lanterns bearing my name differ. They were made by different makers, and I can find no evidence that the defective lantern was ever examined by me. It was made by makers whom I gave up, as they sold lanterns without submitting them to me. Obviously I cannot be responsible for a lantern I have not examined and certified as accurate. I sometimes have to reject a whole batch: There are lanterns bearing my name which are grossly inaccurate.—I am, etc.,

Board of Trade, London,
S.W.1, Nov 23rd.

F. W. EDRIDGE-GREEN.

X-Ray Cinematography

SIR,—You have been kind enough to mention my recent work on x-ray cinematography in the *Journal* several times this year. I should like to record the fact that I am now able to make a cinematograph record of the electrocardiograph tracing and of the heart shadow simultaneously on the same film.—I am, etc.,

London, W.1, Nov. 24th.

RUSSELL J. REYNOLDS.

Obituary

J. STRICKLAND-GOODALL, M.B.,

F.R.C.S.Ed., M.R.C.P.

Physician, National Hospital for Diseases of the Heart

The death of Dr. Joseph Strickland Goodall at the comparatively early age of 60 has come as a great shock to his many friends both inside and outside the medical profession.

Dr. Goodall came from a long line of medical men extending back for six generations, one of whom was President of the Royal College of Physicians. His father was senior surgeon in the Queensland Government Service. He was born in 1874 in Queensland, and spent part of his boyhood in Thursday Island. He was educated at Harrow School and at the Middlesex Hospital, whence he graduated M.B. in 1900. He entered Middlesex Hospital as senior scholar in 1895, and became demonstrator of biology and senior demonstrator of physiology in 1898. He was appointed lecturer on biology to the City of London School and professor of biology and physiology at the City of London College in 1899, lecturer on biology at the Middlesex Hospital in 1900, and lecturer on physiology and pathological chemistry in 1903.

For many years he ran, in conjunction with Professor Earle of Shanghai, an extremely successful and popular course in physiology for the Primary F.R.C.S., which attracted students from all parts of the Empire, and there must be many well-known surgeons at the present time who owe to Dr. Goodall their success in this early and important branch of surgery. In July, 1908, he was appointed subdean of the Medical School of the Middlesex Hospital and member of the School Council. He obtained his F.R.C.S.Ed. in 1910, and the same year was elected F.R.S.Ed. In 1914 he was elected to the staff of the National Hospital for Diseases of the Heart as assistant physician, and became full physician in December, 1923. He obtained his M.R.C.P. in 1915. For many years he was examiner in physiology and biology at the Society of Apothecaries.

During the war Dr. Goodall was consulting cardiologist to the War Office and to the Australian hospitals, retiring after the armistice with the rank of major. During these years he examined and reported on the cardiovascular system of ten thousand recruits. In 1925 he founded a cardiological clinic in connexion with the South Metropolitan Gas Company, and this he still actively supervised up to his death. It was the first clinic of industrial cardiology to be established in this country. He was the first physician in London to restrict his practice to pure cardiology. An extremely hard worker with an enormous consulting practice, he yet always seemed to find time to give helpful advice to his old students, and, indeed, unflinching kindness to all was an integral part of his character.

Dr. Goodall possessed a brilliant brain, full of original ideas, which he was not afraid to employ in the treatment of his patients. The fact that many of these have taken their place as the accepted treatment among large numbers of the profession goes to prove the exactitude of his reasoning. He was to some extent unorthodox in his views, and had no use for the accepted shibboleths unless he could prove their value from personal experience. He was an extremely good teacher, both of physiology and of cardiology, and had to the full the facility of explaining difficult problems in simple language. He kept up his interest in physiology throughout his life, and was Vice-president of that Section of the British Medical Association in 1914. His physiological training enabled him early

to realize the value of the electrocardiograph in the accurate diagnosis of heart disorders. He worked with the late Professor Augustus Waller on the capillary electrometer in the investigation of heart currents, and had installed in the Middlesex Hospital a string-galvanometer as early as 1910. He was thus one of the earliest physicians to use the electrocardiograph in the routine examination of cardiac patients, and many of the electrocardiographic phenomena were first noted by him. In later years his interest from the electrocardiographic standpoint was chiefly towards the elucidation of diseases of the myocardium, and he has contributed many papers and lectures on toxic myocarditis.

He was early interested in the heart in Graves's disease, and his researches in this branch of cardiology have formed the basis of most of the recent work on the thyrotoxic heart. He published many papers, both in this country and in the United States, on various cardiological subjects, and his reputation as a cardiologist was world-wide. For several years Dr. Strickland Goodall was responsible for the cardiovascular section of Savill's *Textbook of Medicine*.

He was a man of very strong personality, beloved by his many patients, rich and poor alike, to whom he never failed to give not only the utmost of his skill but also his unflinching sympathy and understanding. Those of us who knew him intimately felt there was no problem or trouble taken to him which would not receive his most careful and balanced counsel. His death leaves an irreplaceable gap, and many of us will feel lonely indeed when we pass by his familiar door. He was a keen yachtsman, a Liveryman of the Society of Apothecaries, and a Governor of the City of London College. He leaves a widow and one son, to whom the sympathy of the profession is extended.

T. J. H.

Mr. LAMBERT ROGERS writes from the Surgical Unit, Welsh National School of Medicine:

To his many friends the death of Dr. Strickland Goodall will mean a sense of profound loss, for his was an outstanding personality. It is difficult for one who was a student of his, a friend of many years' standing, and on several occasions a patient under his care, to pay adequate tribute to his great ability as a teacher, his kindness, consideration, and helpfulness as a friend, and the supreme confidence and encouragement which he inspired as a doctor. The originality of his thoughts, the clarity of the language in which they were clothed, the calm dignity of his bearing, and the singular directness and simplicity of his manner made a deep impression. If intuition is an instinctive summing-up of memories and other evidences collected by the special senses and correlated by consciousness, one felt that he had it in high concentration; and with him also the study, the teaching, and the practice of medicine were an absorbing passion. One instinctively felt that Dr. Goodall had the Nelsonic attributes of self-reliance, power of initiative, fearlessness of responsibility, and extreme fertility of resource, and his mere presence left his patient with more hopefulness and vitality. When as a young man Sir Richard Douglas Powell asked him what he intended to do and he replied that he intended to concentrate upon and practise cardiology exclusively, Sir Richard said: "You will never make a living from cardiology only." His reply was: "I intend to try, Sir." There was something of John Hunter in his make-up as well—this willingness to try. His students loved him, and looked on him as a tower of strength, and while many of us who were his friends will always be grateful for having known him, at present we cannot but feel a deep sense of loss and sadness, for we may not look upon his like again.

By the death of Dr. ROBERT MONTGOMERY RENDALL, on November 8th, in a nursing home at Bournemouth, following an operation, Nottingham has lost a well-known and much respected citizen, who has not only left behind him a long record of honorable professional work but has also made his mark in the municipal affairs of the city. A Dorsetshire man, a son and grandson of doctors, Dr. Rendall received his training at Guy's Hospital, qualifying M.R.C.S., L.R.C.P. in 1906, and after a period as house-surgeon at Barnstaple and Kidderminster he went to Nottingham in 1910. During the war he served with the R.A.M.C. in East Africa, but on being demobilized in 1919 he resumed his practice in Nottingham. Dr. Rendall took a keen interest in the affairs of the city of his adoption, and became a member of the city council in October, 1922, until this present November, when he did not seek re-election. His principal work on the council was done as chairman of the Mental Hospital and Mental Deficiency Committees. He also was much interested in medical politics, being honorary secretary from 1914 to 1927 and chairman from 1928 to 1931 of the Local Medical and Panel Committee. He was also chairman of the Medical Benefit Subcommittee of the Insurance Committee in 1931-2. At the Nottingham meeting of the British Medical Association in 1926 he was honorary secretary of the Section of Medical Sociology. Mr. A. M. WENNER, F.R.C.S., writes: As one who has known Rendall since we were students together at Guy's, I can say that he was fearless in his determination to right a wrong, especially when the wrong concerned one of his patients. He was devoted to his practice, and was beloved by his patients. He spent as much time and interest on his panel patients as on his private ones. During his long illness he always showed great courage in facing his troubles, and was cheery and optimistic to the end. He leaves a widow, to whom our heart-felt sympathy goes out.

The following well-known foreign medical men have recently died: Dr. BERNHARD PANZER, an eminent laryngologist of Vienna; Dr. HANS BOIT, extraordinary professor of surgery and senior surgeon to the municipal hospital at Königsberg, aged 58; Professor Dr. VIKTOR MATAGA, the first Austrian minister for social welfare, aged 77; Dr. PAUL REYHER, extraordinary professor of children's diseases and director of the Kaiser and Kaiserin Friedrich Children's Hospital at Berlin, aged 58; Dr. CARL ARTHUR HEDBLÖM, professor of surgery at the University of Illinois, Chicago, of coronary thrombosis, aged 55; and Professor TENNI, director of the National Institute of Serotherapy at Naples, aged 70.

The Services

DEATHS IN THE SERVICES

Surgeon Rear-Admiral Alexander Gascoigne Wildey, C.B., R.N. (ret.), died at Churt, Surrey, on November 20th, aged 74. He was born in 1860, the son of William Wallace Wildey, M.D., R.N., was educated at Felsted School and Guy's Hospital, and took the M.R.C.S. and L.S.A. in 1882. Entering the Navy in 1884, he became fleet surgeon in 1900, deputy surgeon general in 1912, and surgeon rear-admiral in 1918, retiring in 1920. As staff surgeon he served in H.M.S. *Cruiser*, a training ship; as fleet surgeon in the battleships *Revenge* and *Illustrious*, and when the war began was at Haslar Hospital. He subsequently served as senior operating surgeon in the naval hospitals at Chatham and Plymouth. In January, 1916, he was appointed to the charge of Gibraltar Hospital; and in 1918, on promotion to surgeon rear-admiral, to the charge of Haslar Hospital, where he remained till his retirement in 1920. He was created C.B. in 1919, and also was an Officer of the Legion of Honour, a Commander of the Order of the Crown of Italy, and received the American Naval Cross. He held also the Gilbert Blane medal, and edited the surgical section of the official naval medical history of the war. In 1889 he married Ruth Amy, daughter of the late paymaster-in-chief, William Horniman, R.N., and had one son and one daughter. At the Annual Meeting of the British Medical Association held at Cambridge in 1920 Admiral Wildey was a vice-president of the Naval and Military Section.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons this week completed its discussion on the Address in reply to the King's Speech, and had a second reading debate on the Electricity Supply Bill. The business of the House of Lords was light.

An Educational Endowments (Scotland) Bill, extending by a further period of two years the powers of the commissioners appointed by the Educational Endowment (Scotland) Act, 1928, was presented in the House of Commons on November 21st by Sir Godfrey Collins.

On November 26th Mr. Oliver Stanley presented the Depressed Areas (Development and Improvement) Bill, to provide for the initiation, organization, prosecution, and assistance of measures designed to facilitate the economic development and social improvement of the depressed areas, and for the appointment of Commissioners for those purposes. The Bill was read a first time.

Infant and Maternal Mortality Figures

Mr. SHAKESPEARE informed Mr. Thorne, on November 26th, that during 1933 there were in Preston 88 deaths of infants under 1 year for each 1,000 births. In Oldham the figure was 72 per 1,000; in Accrington 47 per 1,000; in the metropolitan borough of Wandsworth 51 per 1,000; in West Ham 64 per 1,000; and in the metropolitan borough of Poplar 54 per 1,000. Mr. Shakespeare, replying to Mr. Thorne, circulated, on November 27th, a lengthy tabular statement giving the maternal mortality per 1,000 (live and still) births in a large number of towns and in the Welsh counties in 1933. The statement showed the rate to be as follows:

Dewsbury	6.15	Cardiganshire	9.60
Rochdale	2.71	Carmarthenshire	6.61
Huddersfield	6.81	Denbighshire	7.12
Blackburn	2.63	Flintshire	4.66
Poplar	1.70	Glamorganshire	6.45
Wandsworth	5.27	Merionethshire	4.80
Shoreditch	3.87	Monmouthshire	6.78
West Ham	1.75	Montgomeryshire	6.64
Anglesey	6.85	Pembrokeshire	4.99
Brecknockshire	2.30	Radnorshire	3.10
Carmarthenshire	5.14		

National Health Insurance

Replying to Mr. Llewellyn-Jones, on November 22nd, Sir HILTON YOUNG stated that the approximate number of persons who were notified by approved societies as ceasing to be entitled to medical benefit on December 31st, 1933, by reason of prolonged unemployment, and were not subsequently notified as having resumed employment, was 89,000 in England and 17,000 in Wales. The figures included a substantial number of persons (estimated at about 10 per cent.) who failed to prove that they had continued, up to the end of 1933, to be available for, and unable to obtain, employment. These would not have remained entitled to medical benefit if the Prolongation of Insurance Acts had continued in force. The ordinary medical services would be open to them thereafter. Corresponding figures to June 30th, 1934, were not available.

Sir HILTON YOUNG told Mr. Llewellyn-Jones, on November 22nd, that since 1924 a limited sum of money had been available from national health insurance funds for the improvement of telephone facilities in connexion with the provision of medical benefit in remote rural areas. During the last three years £837 had been expended for this purpose in response to applications from insurance committees in England and Wales.

Mr. SKELTON told Mr. Rhys Davies that the position of manual labour contractors under the National Health Insurance Acts was being watched to ascertain whether any alteration of the law was needed. Certain killers in Glasgow slaughterhouses, who entered insurance in 1929 as manual

labour contractors, were not now regarded as compulsorily insurable, but had been advised that they might continue as voluntary contributors.

Death from Post-vaccinal Encephalomyelitis.—Sir HILTON YOUNG told Mr. Groves, on November 22nd, that he was aware of the death of a nurse, aged 20, at the Queen's Hospital, Birmingham, on October 16th, from post-vaccinal encephalomyelitis, and that Professor Haswell Wilson, a pathologist at Birmingham University, had stated that the condition was due to a reaction of the vaccine, and that the girl would probably not have died if she had not been vaccinated. The lymph used in this case, he understood, was supplied by an establishment licensed under the Therapeutic Substances Act. He was not aware of any enactment under which compensation could be paid in such a case.

Vaccination.—Replying to Mr. Groves, on November 22nd, Sir JOHN GILMOUR stated that during the years from 1924 to 1933 the number of persons proceeded against in England and Wales for offences against the Vaccination Acts, 1867 to 1907, the number of such persons fined, and the number of orders directing vaccination made under Section 31 of the Act of 1867 were as follows:

Year	Persons Proceeded Against	Number Fined	Number of Orders to Vaccinate
1924	246	155	255
1925	221	143	192
1926	176	118	138
1927	148	114	136
1928	182	131	185
1929	129	100	82
1930	119	85	73
1931	73	52	65
1932	87	65	76
1933	118	100	43

Town and Country Planning.—In reply to Sir Francis Fremantle, on November 22nd, Sir HILTON YOUNG said that, at his request, the Advisory Committee on Town and Country Planning had considered draft model clauses, designed to assist local authorities in the preparation of planning schemes, and had made recommendations, which were receiving his consideration. The committee's activities would be recorded in the annual reports of the Ministry of Health. Sir Hilton further informed Sir Francis Fremantle that the report of Lord Marley's committee, on satellite towns, would be presented in time to be considered in relation to the Overcrowding Bill.

Farnborough Institution Hospital.—Mr. Thorne, on November 26th, asked the Minister of Health if he could give any information on the alleged dissatisfaction at the Farnborough Institution Hospital, but Mr. SHAKESPEARE replied that the Minister of Health had no information beyond what had appeared in the Press. The Minister had received no representations with regard to the matter, but was communicating with the Kent County Council, which administered the hospital.

Gas Detection in Mines.—On November 27th Mr. ERNEST BROWS informed Mrs. Ward that last week discussions took place with the Mineworkers' Federation on the draft regulations dealing with the provision of means for detection of gas in mines by workmen underground. Although these regulations were based very largely on the recommendations of the Miners' Lamps Committee of 1922, they were not acceptable to the Mineworkers' Federation. He was considering the objections made by that body.

Increase in Number of Suicides.—On November 27th Mr. SHAKESPEARE informed Sir Arnold Wilson that the attention of the Minister of Health had been called to Table 25 of the Registrar-General's Statistical Review showing that cases of suicide had increased from 3,759 in 1921 to 5,743 in 1932, with an increase of nearly 60 per cent. in age groups 15 and under, and that cases of attempted suicide had increased since 1920 to 1924 from 41.8 per million to 62.1 per million in 1932. The subject had been dealt with from time to time in past reports of the Chief Medical Officer of the Ministry, and would not be lost sight of in future.

Universities and Colleges

UNIVERSITY OF OXFORD

Rolleston Memorial Prize, 1936

The Rolleston Memorial Prize, which is now of the value of about £100, is awarded every two years for original research in any subject in animal and vegetable morphology, physiology and pathology, and anthropology.

No candidate will be eligible (1) who has not either passed the examinations for the B.A. or B.M. degrees at Oxford, or for the B.A. or M.B. degrees at Cambridge, or been admitted as an advanced student, or as a student, for the degree of B.Litt. or B.Sc. at Oxford or as a research student for the degree of M.Litt. or M.Sc. or Ph.D. at Cambridge; (2) who has exceeded a period of six years from attaining one or other of these qualifications, or from his attaining the first of such qualifications, if he has attained more than one; (3) who has exceeded ten years from his matriculation. The next award will be made in Trinity Term, 1936. Candidates wishing to compete must forward their memoir, together with a statement of their present status, where the work was done, and the supervision, if any, which they had, to the Registrar of the University of Oxford before March 30th, 1936. The memoirs may be printed, typewritten, or in manuscript; should be inscribed "Rolleston Memorial Essay"; and should bear the name and address of the author. Memoirs already published are admitted to the competition. For the qualifications of candidates see the *University Calendar* for 1934 (p. 152). No account will be taken of any research which has not been prosecuted by the candidate subsequent to his matriculation.

Radcliffe Travelling Fellowship

An examination for a Radcliffe Travelling Fellowship of the annual value of £300, and tenable for two years, will be held at the University Museum commencing on February 19th, 1935, at 10 a.m.

Candidates must have passed all the examinations required by the University for the B.A. and B.M. degrees. They must not have exceeded four years from the time of passing the last examination required for the B.M. The successful candidate must before election declare that he intends to devote himself during the period of his tenure of the Fellowship to the study of medical science, and to travel abroad with a view to that study. The Fellowship will be vacated 1936 by a Fellow who spends more than twelve months in the whole within the United Kingdom. The examination will occupy four days. Papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay. There will also be a practical examination in pathology. Any candidate desiring to offer in addition a special branch of either medicine or surgery must send notice of this to the Regius Professor of Medicine by February 14th. Intending candidates should send their names, addresses, qualifications, etc., to the Regius Professor of Medicine, University Museum, by February 14th.

At a congregation held on November 24th the following medical degrees were conferred:

D.M.—H. W. Allen.

B.M.—A. G. Palin, R. Kempthorne.

UNIVERSITY OF CAMBRIDGE

Alan Nigel Drury, M.A., M.D., of Gonville and Caius College, Huddersfield Lecturer in Special Pathology, has been elected into a Supernumerary Fellowship at Trinity College.

The Raymond Horton-Smith Prize has been awarded to Herman Taylor, M.D., M.Chir., St. John's College, for his M.D. thesis, "Osteitis Fibrosa, and Experimental Study." Honourably mentioned: W. G. Oakley, M.D., B.Chir., Gonville and Caius—subject, "The Erythrocyte Sedimentation Rate in Nephritis"; and H. B. Stallard, M.D., B.Chir., Gonville and Caius—subject, "Radium as a Therapeutic and a Pathogenic Agent in Certain Ophthalmic Disorders."

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—L. Banzsky, J. E. Darlow, C. McK. Johnston, L. A. Lewis, B. S. Menden, J. P. L. Walley, G. Williams, W. C. Winterbottom.

MEDICINE.—J. E. Darlow, D. S. G. Genge, M. T. Hirst, H. M. R. Waddell, G. Williams, J. E. G. Wright.

FORENSIC MEDICINE.—J. A. Amor, E. St. M. Brett, J. E. Darlow, F. M. Kerry, W. E. Whaite, G. Williams, W. C. Winterbottom.

MIDWIFERY.—C. J. Dandekar, J. E. Darlow, F. A. Frank, H. G. Howitt.

The diploma of the Society has been granted to L. Banzsky, J. E. Darlow, F. A. Frank, H. G. Howitt, C. McK. Johnston, F. M. Kerry, and L. A. Lewis.

UNIVERSITY OF LONDON

A meeting of the Senate was held on November 21st, with the Vice-Chancellor in the chair.

The title of Reader in Industrial Physiology was conferred on G. P. Crowden, M.Sc., M.R.C.S., in respect of the post held by him at the London School of Hygiene and Tropical Medicine.

Medical News

H.R.H. the Duke of York will preside at the Industrial Welfare Society's dinner at the May Fair Hotel on December 11th. Other speakers will include Viscountess Snowden, Mr. B. Seebohm Rowntree, Dr. W. J. O'Donovan, M.P., and Mr. Robert R. Hyde. Further particulars may be obtained from the secretary of the society, 14, Hobart Place, S.W.1.

H.R.H. The Princess Royal will attend a meeting at the Mansion House, on Tuesday, December 11th, at 2.45 p.m., on behalf of the reconstruction appeal for the Hospital for Sick Children, Great Ormond Street. The Lord Mayor will preside, and the Archbishop of Canterbury will be the chief speaker.

The new and reconstructed buildings of the Infants Hospital, Vincent Square, Westminster, S.W., will be opened by the Princess Royal on Tuesday, December 11th, at 3.45 p.m.

The annual dinner of the Medico-Legal Society will be held at the Holborn Restaurant, London, on Friday, December 14th, at 7.15 p.m., with the president, Sir Bernard Spilsbury, in the chair.

The annual dinner of the Old Epsomian Club will be held on Thursday, December 13th, at the Hotel Great Central, Marylebone Road, N.W., at 7 for 7.30 p.m. The principal guest of the evening will be Lord Leverhulme, the new president of Epsom Club.

A symposium on "Technical Aspects of Emulsions" will be held at the Royal Society of Arts, John Street, Adelphi, W.C.2, on Friday, December 7th, from 10 a.m. to 6 p.m., under the auspices of the British Section of the International Society of Leather Trades Chemists. Professor F. G. Donnan, F.R.S., will preside.

The next series of lectures and demonstrations on tropical hygiene, intended for men and women outside the medical profession proceeding to the Tropics, will be given by Lieut.-Colonel G. E. F. Stammers and Sir Malcolm Watson from December 10th to 14th (from 3.30 to 5 p.m. each day). Particulars can be obtained from the organizing secretary, Ross Institute of Tropical Hygiene, Keppel Street, W.C.1.

A series of lectures on cancer will be given in the lecture theatre of the Cancer Hospital (Free), Fulham Road, S.W., on Thursdays at 4 p.m. from January 3rd to April 11th, 1935, inclusive. No charge is made for attendance at the course, which is open only to medical practitioners. The individual lectures will be announced week by week in the diary column of the *Supplement*.

Dr. F. R. Seymour will give a public lecture under the Chadwick Trust on "Men and Masses: Phases of Man's Relation to Disease" in the lecture theatre of the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Monday, December 10th, at 5.30 p.m.

The Deutsche Gesellschaft für Wissenschaftliche Filme of Berlin is giving a private demonstration of German medical and surgical films in the Academy Cinema, 156, Oxford Street, London, W., on Sunday, December 16th, at 11 a.m. Members of the medical profession are invited to attend. Admission is free on presentation of a visiting card. The following films will be shown: fertilization and first segmentation of the rabbit ovum; version and extraction in transverse lie; normal and malignant cells *in vitro*; tumours of the brain, technique of operation after Olivecrona; action of the heart; and cholecystectomy in empyema of the gall-bladder.

The Fellowship of Medicine (1, Wimpole Street, W.) announces that lecture-demonstrations will be given at 11, Chandos Street, W., on December 4th and 11th, at 2.30 p.m.; also lectures on Wednesdays at 8.30 p.m., on diet and dietetics. On December 8th, at 3 p.m., at the National Temperance Hospital, Dr. B. T. Parsons-Smith will demonstrate heart cases. There will be a special M.R.C.P. course in chest diseases at the Brompton Hospital on Wednesdays and Fridays, at 5 p.m., from December 12th to January 11th (excluding Christmas week). Courses for the New Year are being arranged as follows: cardiology, at the National Hospital for Diseases of the Heart, January 14th to 25th; urology, at St. Peter's, January 21st to February 2nd; diseases of the heart and lungs, at the Royal Chest Hospital, January 19th and 20th; manipulative surgery, January 29th to February 1st; a series of surgical tutorial classes on Tuesday and Thursday evenings, at the National Temperance Hospital; and a series of demonstrations at the Wellcome Museum of Medical Science, on Thursday afternoons. Full details of all these courses (which, with the exception of the cardiology course, are open only to members and associates of the Fellowship) will be available shortly.

Sir Henry Wellcome, founder of the Wellcome Research Institution, London, was received at the Elysée in Paris, on November 23rd, by President Lebrun, who decorated him with the cross of the Legion of Honour.

The Treasury, on the recommendation of the Import Duties Advisory Committee, has made an Order adding to the free list as from November 26th, 1934, catalogues not being trade catalogues; and advertising material, not being trade advertising material. Some time ago the Treasury, on the recommendation of the committee, removed from the free list and imposed additional duties on catalogues and advertising material other than such as are imported by post in a packet not exceeding 8 oz. in gross weight. In making its recommendation at that time the committee had in mind bulk importations of such catalogues and advertising material as are issued by way of trade or business; but the effect has been to subject to duty, when imported in bulk, certain literature, particularly learned publications, which it was not the committee's intention should be so charged. The purpose of the latest recommendation and Order is to exempt this literature from duty.

The American Association for the Study of Goiter again offers the Van Meter prize award of 300 dollars and two honorable mentions for essays provided they meet the standards of the award committee. The essays should be based on original research work on the subject of goitre, preferably its basic cause. The prize essay or its abridgement is to be presented at the annual meeting of the Association to be held in Salt Lake City, Utah, in June, 1935. Competing manuscripts should be in the hands of the corresponding secretary, W. Blair Mosser, M.D., Kane, Pa., not later than April 1st, 1935. The first prize of 300 dollars for the 1934 meeting was awarded to M. A. B. Brazier, Ph.D., B.Sc., London, England, for her essay "The Impedance Angle Test for Thyrotoxicosis." First honourable mention was awarded Professor Ugo Cerletti, Genoa, Italy, for his essay "Three Years of Experimental Research in the Etiology of Endemic Goitre." Second honourable mention was awarded Dr. Roy McCullagh, M.D., Cleveland Clinic, Cleveland, Ohio, for his essay "Studies in Blood Iodine, using a New Chemical Method."

New methods in the diagnosis and treatment of rheumatic diseases will be discussed at a medical meeting of the Charterhouse Rheumatism Clinic (15, Portland Place, W.) on Thursday, December 13th, at 5 p.m. Medical practitioners are invited to attend, but should inform the secretary, as the accommodation is limited.

An International Therapeutic Union has recently been founded in Paris, on the initiative of the Société Française de Thérapeutique, under the presidency of Professor Loeper of Paris. The new society will meet once a year, and will hold a congress every three years. The first of the kind will take place in 1936 at Berné, under the presidency of Professor Burgi.

The Société de Neurologie of Paris has awarded the Déjerine prize to Dr. Laruelle, head of the neurological centre in Brussels, for his work on the microscopical anatomy of the spinal cord in segmental longitudinal sections.

Mr. Frederick Priestman, a former mayor of the City of Bradford, left £137,336. His bequests included £10,000 to Bradford Royal Infirmary, less any sums paid in his lifetime, towards the fund for building a new infirmary.

After allowing for certain bequests amounting to some £7,200, the residue of the estate of Mr. J. A. Atkin of Highgate, who left £39,341, goes to King Edward's Hospital Fund.

The King has appointed Dr. G. L. Milburn to be an official member of the Executive Council of the Presidency of Saint Christopher and Nevis.

The academic council of the University of London has passed a resolution recognizing the Institute of Medical Psychology as an approved clinic in connexion with the post-graduate diploma in psychology.

According to official statistics there are at present fifty-one lepers in Norway, thirty-six of whom are in two hospitals at Bergen and two in a hospital at Oslo, while thirteen are mild cases isolated in their own homes.

Professor Sacquépée has been elected to the Académie de Médecine, in the place of the late Dr. Calmette.

An Italian Society of Anaesthesia and Analgesia is being founded in Rome on the initiative of Professors Alessandri, Tusini, Uffreduzzi, and Dogliotti.

A historical surgical museum has been founded in the Institute of Experimental Surgery at Buenos Aires under the presidency of Professor G. B. Arana.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the British Medical Journal must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the Journal, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the British Medical Journal is EUSTON 2111 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:
EDITOR OF THE BRITISH MEDICAL JOURNAL, Adelcy Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westcent, London.
MEDICAL SECRETARY, Medisecura Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: Buellins, Dublin); telephone: 62550 (Dublin), and of the Scottish Office, 7, Drummond Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Chronic Enlargement of the Lip

Dr. H. L. PEARSON writes: I should be glad if any of our readers could give me a hint regarding the treatment of the macrocheilia. The patient is a middle-aged woman, and the duration of the trouble under a year; it affects only the lower lip. She had a deep, septic fissure in the middle of the lower lip, and some carious teeth; all the teeth were taken out some months ago; and the mouth is clean and the fissure healed. The Wassermann reaction is negative. Potassium iodide, 30 grains, t.i.d., has been and is still being given. A consultant has suggested excising of a V-shaped piece of the lower lip. Can anyone offer an alternative?

Quinoldine

Dr. D. PATERSON LEIFER (Glasgow) writes: I shall be much obliged if any of your readers can inform me as to the method adopted by Bence-Jones in the extraction of "quinoidine" from the skin, and the chemical tests used for the detection of this substance.

Priapism After Circumcision

Dr. J. BARCROFT ANDERSON (Hampstead, N.W.3) writes: The condition "D. R." refers to in his query (November 24th, p. 975) is probably due to the subcutaneous fibrous ring which surrounds the base of the penis being too small. It should be as easy to dilate it as to dilate the prepuce in the manner recommended by the late Dr. Whittla of Belfast. I have noticed that in some South African natives this ring seems to be almost absent.

European Children in the Tropics

Dr. JAMES GARDNER writes from Gourock: I have been asked the following question, and as I cannot answer it I pass it on to the *Journal*. Why is it that English people cannot live in the coast towns of Java the whole year round, but have to go up to the hills part of the year, and have to send their children home to England for their health, whilst Dutch couples will go out to Java, live in the coast towns all the year round, and rear and educate their children there, and maintain their health without sending them home to Holland? The question arises from the general statement that the children of English parents, born in the hot countries of the East, have to be sent home to England before they are seven years old, otherwise they will die or become ill both bodily and mentally. Naturally, I am writing on the assumption that the statement about the Dutch children is true, and I am assured that it is, and I am also under the impression, from what I have read, that the Dutch do settle, live, and thrive in the hot climate of Java, and make it their home in a way the English have never done in India.

Income Tax

Resident Patient—Expenses

"J. B. D." has had a resident patient since August 7th; he is liable to pay 10 per cent. of the first year's fees to the bureau through which the arrangement was made. Is this deductible?

* Yes. It is a reasonable expense, analogous to fees payable to a house agent for a furnished letting. In addition, of course, "J. B. D." can deduct a reasonable proportion of the general household expenses, according to the quality of the dietary and accommodation afforded.

Purchase of Practice—Basis of Accounts

"O. P. G." has bought a practice, and the accounts for his first year have just been completed. The local inspector objects to the cash basis, and wants an account on "a credit basis." "O. P. G." states that "the return will then run on the amount earned for five, not four, quarters."

* The inspector is correct in his objection to the cash basis for the first year or two, unless the outstanding debts have been purchased and are being brought into the account. The point is that income is taxable when earned, not when received. Where an account is prepared on a basis of total bookings the debts outstanding should be valued as at the commencement and end of the period, and the increase or decrease in the anticipated loss brought into the account. The simplest method is to start from the cash takings and add (or deduct) the increase (or decrease) in the net value of the outstanding debts. It is admittedly particularly difficult to value medical debts, but this is usually appreciated by inspectors. We do not follow the contention that five quarters' income will be brought in if, as is understood, the account "for a year only."

Foreign Dividends: Blocked Account

"J. P." refers to a previous reply—in the *Journal* of November 25th, 1933—and forwards his local bankers' credit note showing that his "pesos" account has been credited with a dividend less United Kingdom income tax.

* It would seem that the paying agents here of the Chilean company have been put in possession of credits, and to that extent remittance to this country has been made and tax properly, therefore, deducted, but that so

long as the account remains "blocked" "J. P." cannot draw on it. Such arrangements, however, may differ in point of detail—possibly the bank manager can give further particulars of the precise nature of the "blocking" scheme. It may be added that presumably the same restriction applies to the amount deducted as tax—that is, the Revenue Department is as unable to get the tax into its coffers as "J. P." is to get the net dividend into his pocket.

Dominion Income Tax on Colonial Pension

"X Z" has a Colonial pension on which Dominion income tax has been paid at 7½d. in the £—that is, the "appropriate rate." The English department claims that he cannot be repaid the whole of this Dominion tax.

* The department is apparently correct. The amount of the "relief" due here is determined by applying the "appropriate rate" to that part of the income on which United Kingdom tax is paid or payable. As he is entitled to "relief from earned income," there is a fraction—1/5 of the gross amount—at present on which he does not pay United Kingdom tax. As a result he is left in the position of having to bear a part of the Dominion tax.

LETTERS, NOTES, ETC.

Evipan Paralysis?

Dr. F. B. MALLINSON (Anaesthetist to St. John's Hospital, London, S.E.) writes: I notice that whenever a new drug or method is introduced, and in due course weighed in the balance and found not wanting, a certain number of medical men who experience trouble during its use at once write and demonstrate that the trouble must be laid to the door of the particular agent. I read in your issue of November 24th (p. 940) an account of a case of severe peripheral neuritis following evipan anaesthesia for a widespread and grave condition of sepsis. This was at once put down to the evipan (backed, I admit, by the opinion of one of the greatest opponents of the barbiturate group of drugs), and the account labelled "A Case of Evipan Paralysis." Why? Surely a more obvious and rational explanation would be that of a toxic peripheral neuritis due to the intense toxæmia the patient must have suffered. Also it would be an explanation less prejudicial to one of the safest and most important additions to the anaesthetist's armamentarium. I have used evipan in a large number of cases of varying degrees of toxæmia without encountering a similar phenomenon, but at the same time a good many cases have been reported from time to time of severe peripheral neuritis, the result of grave toxæmia.

Dr. G. H. MORRISON (Medical Adviser, Bayer Products Ltd.) writes: In the account of the case of paralysis reported from Singapore which followed the administration of "evipan" sodium anaesthesia, as published in the *Journal* of November 24th (p. 940), there occurs a statement which is obviously made in error. The statement is: "The patient in our case was admittedly very ill and emaciated before operation, but it is in just such cases that the manufacturers [of "evipan" sodium] recommend full doses." If you will refer to the leaflet issued by the manufacturers (a copy of which I enclose) you will find the following: "... it is of course obvious that seriously ill, old, and cachectic patients, and those with circulatory and respiratory disturbances, must be treated with individualized care. . . ."

Maternal Morbidity: Prophylaxis

Dr. WM. HARVEY BENNETT (Bolton) writes: From the evidence put forward at the meeting at the Friends House, Euston Road, on November 6th, it appears that no remedy has yet been found for the deplorable state of affairs pointed out by the late Dr. Ballantyne of Edinburgh twenty years ago. In spite of much ante-natal work the mortality and morbidity of child-bearing women has not been reduced. During the past eight years it has been my practice to invite all women who engage me to attend them during confinement to visit my surgery for radiation by ultra-violet rays at least once a week. The results have been most gratifying, as there have been no complications in any of the cases—about thirty in all. The general condition of the mother has been obviously improved during both pregnancy and puerperium. Calcium and phosphorus metabolism appears to be stimulated—a very important fact for both mother and foetus. There has been no rise of tem-

perature in any case. Those who were previously unable to feed the baby naturally have been enabled to do so. There has not been the slightest evidence of rickets in any of the babies or of osteomalacia in a mother. The dosage of vitamin D has not been considered, but has evidently been sufficient. My investigations have been very incomplete, as my cases are few, and x rays are not available to study the bone changes, as Dr. Rollier has studied them at Leysin in his clinics for heliotherapy. The cost of this treatment, excepting for the time spent in administering the light, is negligible, and the cases are under the closest observation from an early date in pregnancy.

Psychology and Religion

Dr. RICHARD KAY (Hartland, N. Devon) writes: In his exceedingly interesting address on psychology and religion, reported in the *Journal* of November 24th (p. 958), Dr. David Forsyth says "the reason for the almost universal belief in immortality needed accounting for." May I suggest that it is due to the rationalization by primitive man of the instinctive avoidance of danger, common to most slow-breeding animals, into the fear of pain and death. To fear death is to wish to live for ever, which is contrary to experience. But the idea has been born, and the instinct, still active, gives us a strong bias in favour of any argument or experience which suggests that death is not the end of the individual.

Prevention of "Steaming" Glass

Dr. F. A. E. SILCOCK (Leicester) writes: With reference to the letter on prevention of "steaming" glass, by Dr. J. Roland Murdoch, in your issue of November 24th (p. 976), I desire to state that for very many years now I have used a method that is at once simple, inexpensive, and readily obtainable anywhere for my eyeglasses, surgical mirrors, and so forth. Rub some moist soap over the glass surface and polish it off with a piece of rag again. Ordinary hard-household or toilet soap, when it is "tacky"—for example, after one has recently washed one's hands with it—will do. The effect lasts for several hours. I think the soap acts by lowering the surface tension. Other substances will do the same, but soap has obvious advantages.

Dr. J. PERCIVAL BROWN (Bacup) writes: A very old tip used by me for all mirrors, glasses, etc., is to rub on a bit of ordinary hard, dry soap and then polish off. Any mirror is thus also easily prepared for a patient to get close to it to remove blackheads in acne cases. It is useful in a bathroom to prevent steaming of a mirror, etc.

Inquiry into Contraception

The Acting Secretary of the National Birth Control Association, of which Lord Horder is president, writes: This association has appointed a medical subcommittee consisting of practitioners actively engaged in the teaching of contraception. The object of this committee is to collect, co-ordinate, and from time to time draw up for publication authoritative information on all aspects of contraception for the use of the medical profession. The committee is in consultation with research workers, manufacturers, birth control clinics (both voluntary and under the public health authorities), and doctors engaged in teaching contraceptive methods throughout the country. Although much valuable experience exists, the results of which are at the disposal of the N.B.C.A., the whole subject is still at the research and experimental stage, and it is necessary to be constantly reviewing and reassessing the methods in current use. This committee would therefore be glad to hear from any doctor, clinic, or manufacturer interested in birth control, in order that it may have the fullest sources of information possible. All communications should be addressed to the secretary, National Birth Control Association, 26, Eccleston Street, S.W.1.

Motor Backache and Neuralgia

Dr. TOM A. WILLIAMS (Bordighera) writes: Pain in the back from motoring is surely due to prolonged stretching of extensor ligaments and muscular attachments, aggravated by the sudden further drag when the body is jolted backwards, forwards, or sideways by bumpings of the car. There are two factors at work. The "close-ribbed" person sags less; hence ligamental and muscular attachments are scarcely stretched. Further, he fits better the usual seat. The long-backed person is farther stretched, and rarely is fitted, especially in a small car. My own remedy is to place a cushion in the small of the back about one foot square and three inches thick, firm enough to support the

shoulders and maintain the lumbo-dorsal extensor curve into which it fits, and soft enough to accommodate itself to the space made by the mis-shape of the back of the seat. In my case this has prevented ache and strain in many a thousand-mile trip over rough roads during the past twenty years. The same device used in bed cures many a back pain reputed to be "neurasthenic" or "imaginary" or "psychological"—so often lightly dismissed by the loosely thinking. Just so, motor backache can be cured only by rest and massage, but can be prevented, even when the seat is ill constructed, by a cushion properly made.

Varicella and Herpes

Dr. D. JUSTIN DAVIES (Leicester) writes: The close relation between the virus of varicella and herpes zoster is now an accepted fact. An address—I believe by Dr. James Collier—was published some years ago in the *British Medical Journal*, concerning the possible connexion between the viruses of acute infections of the central nervous system and those of varicella and herpes. The following cases are therefore, I think, of some interest. A girl, 10 years of age, suffered five years ago from acute anterior poliomyelitis. The result of this illness seems to be confined to the left lower limb, which is now much smaller and shorter than its fellow. She recently developed varicella. A profuse eruption appeared on the trunk and scalp with numerous spots on the face and limbs (with the exception of the affected limb, which was completely free of spots). Some time ago I attended a boy suffering from encephalitis lethargica, whose mother and father both subsequently developed herpes zoster.

Medical Register: Office Edition

The Registrar of the General Medical Council writes: Any orders for the Office Edition of the *Medical Register, 1935*, published by the Council at the special price of 10s. a copy, post free, must be received, with a remittance, at the office of the Council, 44, Hallam Street, Portland Place, W.1, not later than December 31st, 1934. The Office Edition differs from the ordinary edition of the *Register* to the extent that it does not contain reprints of the Medical and Dentists Acts and other preliminary matter, and is printed on more inexpensive paper and bound in boards. It includes, however, the same entries relating to registered medical practitioners as are included in the ordinary edition, and is therefore equally serviceable to public authorities and others who find it necessary to ascertain whether particular persons are registered medical practitioners or not. I take the opportunity of stating that the Council also prepares monthly lists of names added to, and removed from, the *Register*, and that particulars of the terms and conditions upon which copies of these lists may be made available can be obtained on application to the office of the Council.

Corrigenda

Dr. E. HARVEY (Dublin) wishes to make a correction in the report of the meeting of the Royal Academy of Medicine in Ireland on November 2nd, which was supplied to us for publication by the secretary (*Journal*, November 17th, p. 919). Dr. Harvey writes: "Monkeys and pigeons were the experimental animals used by Sir R. McCarrison—not rabbits, as I am made to say. It was in the monkeys, put on a diet of autoclaved rice and fresh butter, that conditions were produced which bear a close correspondence to those found in coeliac disease (or Gee's disease)."

Another apology is due to the shade of Horace. The quotation amended last week (p. 976) should read "... *animus lento-temperet risu*."

An exhibition of microscopes, conducted by Messrs W. Watson and Sons, Ltd., will be held in the Conference Hall of the Central Hall, Westminster, S.W., from December 10th to 15th inclusive, and will be open from 2.30 p.m. each day.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 54, 55, 56, 57, 60, and 61 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 250.

THE OPERATIVE TREATMENT OF FACIAL PALSY*

BY

ARTHUR BALDWIN DUEL, M.D., F.A.C.S.

SURGEON-DIRECTOR, MANHATTAN EYE, EAR, AND THROAT HOSPITAL, NEW YORK, U.S.A.

(With Special Plate)

LECTURE I

I am especially pleased to accept the invitation to address you since it offers me the opportunity, here in his own circle of conferees, to pay tribute to the genius of my dear friend and colleague Sir Charles Ballance in this work. But for him I should never have undertaken it. Whatever of interest I may be able to present to you results from the inspiration of having worked so long with a man of such unequalled skill, such indomitable energy, and such amazing industry.

Historical

Nearly six years ago Sir Charles and I began working together on animal experimentation at my country place in the Berkshire Hills, seventy miles from New York. A laboratory quite adequate for our purpose was built and maintained, at first through the generosity of a few personal friends, and later by subsidies from four foundations.† Our first effort was to verify certain conclusions which Sir Charles had arrived at in a series of experiments on rhesus monkeys in England. After the performance of experimental operations on monkeys, in which the peripheral end of the divided facial nerve was united to the central end of another divided nerve of the neck, no test had been made to determine whether the divided ends of the facial nerve had reunited. If they had done so, the result of the experimental sutures would have been vitiated. Hence we repeated these experiments, and in each of them the central segment of the facial nerve was removed from the aqueduct. Some months later the brain was removed and the nerves in the posterior fossa stimulated with the faradic current. The facial nerve at the internal auditory meatus on the side of operation was stimulated, but no response in the muscles of the face occurred. If the facial nerve had been sutured to another nerve—for example, the glossopharyngeal—stimulation of the glossopharyngeal nerve in the posterior fossa resulted in contraction of the muscles of the face. We then sought some method by which the associated movements, accompanying cure of facial palsy by suture of the facial nerve to various motor nerves in the neck, might be eliminated.

Direct Line Repair

The idea occurred to us to attempt a direct repair of the facial nerve by introducing a piece of freshly excised graft from another nerve into the gap made by the removal of a piece of the facial nerve in the aqueduct.

* Two special lectures delivered at the Royal College of Surgeons of England on October 10th and 11th, 1934.

† The Carnegie Corporation; The Milbank Foundation; The Lillian Babbitt Hyde Foundation; The New York Foundation.

Accordingly, on August 27th, 1930—on a mandrill baboon—the facial nerve was divided in two places in the aqueduct 5 mm. apart, and reversed. On September 19th, in a hamadryad baboon, a segment of the facial nerve 6 mm. in length was removed and replaced by 6 mm. of fresh graft removed from an intercostal nerve. Both subjects recovered the use of their facial muscles. They were the first animals on which a direct line repair had been attempted. Subsequently we did a large series of experiments with grafts.

At the end of a year we had demonstrated that facial movements could be restored by introduction into the gap of a divided facial nerve, from which sections had been removed, of freshly excised autoplasmic grafts of any desired length, either from motor or sensory nerves, either reversed or unreversed. These restored nerves conveyed both voluntary and emotional impulses. The muscles moved synchronously on both sides of the face, and there were no grotesque movements such as occurred after recovery following suture of the facial nerve with other motor nerves in the neck.

No one had inspected the facial nerve at the seat of injury in the various nerve-anastomosis operations in human cases, and consequently there were no statistics to guide us as to the extent of the gap in the divided nerve. We had supposed that it might be 5 mm. but not more than 10 mm. Subsequent work showed us that this was a gross underestimate. We felt that a gap of about this amount could be repaired by a graft taken from the external respiratory nerve of Bell (long thoracic nerve), without placing too much traction on the ends of this nerve when it was reconstituted. However, when gaps of 40 mm., and in one case 200 mm., had been bridged it was obvious that another nerve had to be used in which restoration of continuity was not essential. For this reason a sensory nerve was eventually selected, after experiments with intercostal nerves had been made. The anterior femoral cutaneous nerve provided lengths more than sufficient for any of our cases, and was our final choice.

Clinical Cases

The first human case in which a fresh graft was used, taken from the exterior respiratory nerve of Bell, was in an infant 18 months of age.

There had been an acute infection by the *Streptococcus haemolyticus* of the middle ear and mastoid air cells, with a post-auricular subperiosteal abscess. The young operator had proceeded as if he were dealing with an adult mastoid. As a result we found the facial nerve absent from a level just below the horizontal semicircular canal to the posterior border of the parotid gland. The exploration was made twenty-four days after the injury. It was possible to identify the facial nerve by faradic stimulation of the stump protruding

from the parotid gland, otherwise a much more extensive dissection would have been necessary. (Faradic response in the distal segment of a divided facial nerve remains for from forty-eight to seventy-two hours. I have verified this in over fifty monkeys, and several times in man. Hence the importance of early investigation of cases of traumatic origin.) Twenty-seven millimetres of graft were employed in this case. The proximal end was laid up against the proximal end of the divided facial nerve; the distal end was sutured to the distal stump by one strand of "000000" silk. The patient eventually recovered the use of her face (see Figs. 1 and 2 on Special Plate).

The second case presents a striking contrast of conditions.

The patient, a female aged 34, suffered from a chronic purulent otitis, for which a radical operation had been done. Immediate facial palsy had ensued. She was first seen by me eleven months later, when, after removal of 37 mm. of injured facial nerve from the tympanum to a point several millimetres distal to the foramen of the Fallopian aqueduct, the facial nerve was reconstituted by a freshly excised graft from the nerve of Bell. The wound was infected. She eventually recovered, with a straight face in repose, and good, though not perfect, synchronous movements, both voluntary and emotional (see Figs. 3 and 4 on Special Plate).

We learned much from these cases. First, we proved that suppuration was not a bar to successful transplantation of grafts. In the last four years, in a series of sixty-nine operations on facial palsy, a large majority have been done in the presence of infected wounds. Necrosis of a graft on account of infection has occurred only once. In that case a second effort was successful. Secondly, we discovered that injuries involved a larger extent of the facial nerve than we had supposed. Of the sixty-nine operated cases in my series forty have required grafts in the Fallopian canal. These forty cases have had gaps on an average over 20 mm. in length. The shortest was 7 mm., the longest 40 mm. This does not include a series of five cases in which operations on tumours of the parotid gland resulted in gaps in the facial nerve more than 40 mm. in length. In one case 200 mm. in four strands, from the proximal stump at the stylo-mastoid foramen to the divided distal branches in the face, were required. In the course of a year I operated on thirteen cases of facial palsy: eight of them necessitated grafts varying from 8 mm. to 36 mm. in length. Successful transplantation of fresh grafts was effected in all but one, and that succeeded on a second trial. Varying degrees of recovery took place, and I had an opportunity of studying the results.

Mechanism of Repair Process

The one phenomenon that gave me constant cause for speculation was the fact that in every case there was a period of waiting, followed by a response to faradic stimulation, and then spontaneous movements of muscles. In the case of a slight injury to the sheath of the facial nerve, with infection and inflammatory compression, a successful result had been obtained by decompression and slitting of the sheath of the nerve in the aqueduct. Faradic response (followed by spontaneous movement in the muscle) occurred in a period measured by weeks. In the chronic cases, in which a graft had been necessary, the interval between the time of repair and the first evidence of faradic response in the muscles was very much longer—measured by months instead of weeks.

In either case, once a faradic response appeared the subsequent improvement in the muscles was about the same. Now we all know that when a nerve is injured (to a degree that destroys its power to convey faradic stimuli), from the point of injury down to the last end-plate the nerve cells are rendered ineffective. The restoration of function in the distal segment must follow degeneration and removal from the conveying tubes of

all the now useless neural fibres, followed by a growing-in, from the proximal segment, of new axons to take their place.

Now this degeneration and emptying process occurs rapidly after any serious injury of the facial nerve. The axons distal to the injury are rapidly disintegrated. The products of this disintegration are removed by the circulation, leaving the conveyors—the empty tubes—ready to receive the axons, which are pushed on through the proximal segment, from the central nuclei. This can all happen in the course of a few weeks, and we consequently see—in acute cases, where the conveyance of neurons has been facilitated by decompression of the nerve—recovery taking place in a relatively short period of time. Why, then, the long delay in the case of grafts? The distal segment has long been empty, Wallerian degeneration being complete. Speculating over this it seemed probable that the obstruction was offered in the graft, which as soon as it was transplanted became part of the distal segment. The fresh graft was full of non-degenerated axons; they must be degenerated and removed before it can be utilized as a conveyor. This is a slow process with the meagre circulatory apparatus with which the graft is provided in its transplanted bed. It is enough to ask it to live for a long period in its new environment without it having to deal with the complex problem of getting rid of thousands of degenerating axons.

But if this graft were like the rest of the distal segment—that is, if its tubes had been cleared by Wallerian degeneration—it could live in its new environment in exactly the same way, and yet, being clear of these obstructing, useless neural elements, might be ready immediately to act as a conveyor. Why not, then, cut the nerve, which one proposed to utilize eventually for graft material, and allow it to remain *in situ*, undisturbed as to circulation, until Wallerian degeneration had advanced sufficiently, so that when a portion of it was used as a graft the emptied tubules would no longer offer an obstruction to the advancing neurons from the proximal segment of the facial nerve?

The plan was tried on a series of rhesus monkeys. The anterior femoral cutaneous nerve was severed and allowed to remain in its bed for varying periods from eight to thirty-five days—so that Wallerian degeneration could readily take place. The facial nerve was severed at the same time—so that Wallerian degeneration might take place, *pari passu*, in it as well.

When portions of the nerves treated in this manner were used as grafts facial response was restored in one-quarter to one-half the time formerly required by fresh grafts. I obtained faradic response in from sixteen to twenty-six days through 10 mm. of prepared graft—that is, graft already degenerated after the grafting operation.

Having proved its efficacy on monkeys, I began two years ago to employ the method in man. I have now used it in thirty cases. Faradic response has come through much earlier in all cases. In a number of cases this was as early as thirty days after transplantation. It has not been unusual, when I have employed prepared grafts, to observe a state of progress in six or eight weeks, only reached in six or eight months in the earlier cases where fresh grafts had been used. The degeneration in the nerve to be used as a graft requires two to three weeks. The additional time in hospital is well expended, since it saves so many months in the final recovery.

Details of Operative Technique

May I digress at this point to say how important I consider practice on cadavers and monkeys to be for any surgeon who is to attempt this work, no matter how skilled he may be in the usual operations on the temporal bone. On any particular case it seems to me essential

for the best good of the patient that the operator should have in mind definitely what he proposes to do. This should be acquired by previous practice. Trial and success, or trial and failure, may definitely fix the operator's mind as to what he may or may not do. For example, I had worked up a technique on the cadaver, with a motor-driven burr, which I hoped would materially shorten the time of exposure of the nerve in the aqueduct. On my fourth effort, when I fancied I was becoming quite proficient, a catastrophe occurred which made me abandon the motor-driven burr for all time, in favour of a slower but surer method. No one can tell you how you are to do your own ivory carving. You must do it your own way, with your instruments, according to a plan you have learnt; you should not practise on your case in hand, but carry out your previously determined method. You may on your second, or fourth, or fifth case change your plan of operation for your third, fifth, or sixth. Practise the change of idea on the cadaver before attempting it on the living case. You may change your mind after trying it, as I have done on two or three occasions, for the good of the patient.

Instruments.—A word regarding the details of operation and after-care. As I have said before, each operator must practise with his own instruments, in his own way, the method of removal of the bony wall of the aqueduct. I personally have discarded the use of a motor-driven burr, or a chisel, or a gouge. While these may be faster, I feel that I am by this method sacrificing speed to accuracy. I prefer small rongeur forceps, hand gouges, and straight curettes with non-flexible shanks. All of these should be very sharp. I also devised a number of hand burrs and files, which I have now discarded. Practice on the cadaver with favourite models has helped me more than newly devised instruments.

Exposure.—I always uncover the nerve by removal of the outer wall of the aqueduct, working from the stylo-mastoid foramen upward. In every instance the outer wall of the canal up to the site of injury and for a few millimetres beyond should be removed. I find that the exposure of the nerve is greatly facilitated by removal of several millimetres of the floor and posterior bony wall of the external auditory meatus. This is particularly useful as one approaches the narrow and deep portion of the aqueduct lying between the horizontal semicircular canal and the oval window. This truly represents the Scylla and Charybdis of the operation. Fortunately, in many of the cases it is unnecessary to remove this part of the aqueduct. It is never necessary to do so in decompression for Bell's palsy. Injuries to the nerve above the level of the horizontal semicircular canal occur rarely, except in radical mastoid excavations. When it is necessary to uncover this portion of the nerve the only safe approach is from before backward, through the posterior bony canal wall and hypotympanum. Cracking through the horizontal semicircular canal above and dislocation of the stapes below are the two great dangers. The removal of the bony covering from this point up to the geniculate ganglion is very easy, as it has only the thickness of stiff tissue paper.

Neurectomy and Insertion of Graft.—The nerve having been uncovered from 5 mm. above the site of injury to the stylo-mastoid foramen, the sheath should be slit open with the sharpest of Graefe knives over all this area. The sheath must not be torn apart; it must be gently incised. When the tube is laid open the bundle of nerve fibres appears. Inspection in every instance will show the site of injury where scar tissue may be expected to form during healing, or where scar tissue is already present. The distal segment—that is, the nerve beyond

the injured or scarred zone—should be cut well beyond the lowest point of scarring, and the injured segment of nerve removed. The neuroma of the proximal segment should be cut off cleanly and squarely. This must be done gently to avoid crushing of the axons. Crushing instead of cutting with the keenest of blades either of the proximal or distal ends of the facial nerve or of the graft will immeasurably delay the time of recovery. The length of the gap does not matter. The distance can then be measured, the graft taken from the "prepared" anterior femoral cutaneous nerve, and laid in. The graft should be long enough so that it may be tucked in rather than stretched between the freshly excised ends of the facial nerve.

Haemorrhage.—This formerly gave me much concern, and I have spent hours in stopping it with hot saline solution before inveigling the graft into position. The use of adrenaline, peroxide, and other haemostatics is most inadvisable. What I have now learnt is that if the ooze of blood from the bone and soft tissues is temporarily stopped, so that the ends of the graft can be opposed to the sectioned facial stumps, they almost immediately become glued together sufficiently to prevent the entrance of blood. The subsequent ooze about the graft provides a fibrinous bed which fixes it in position. There is no doubt that a blood clot between the divided ends will delay the advance of the axons very considerably.

Embedding.—The slit sheath is gently laid up against the graft, and the incision covered with a strip of dentist's gold leaf. The wound is left wide open, and packed loosely with short wicks of sterile gauze, wrung out of sterile normal salt solution. The gold simply prevents the gauze from sticking to the graft and disturbing it in subsequent dressings. The dressing superficial to the gold leaf should be changed daily, until the whole graft is embedded in healthy granulations. The gold may or may not be removed in two or three weeks. It has often been left in, and has proved quite innocuous. At the end of a month, if the wound is quite healthy, it may be closed by a plastic operation. I have found it a great advantage to postpone the plastic operation for a month. The anaesthesia for this operation makes it possible at such a time to try a faradic current of sufficient strength to demonstrate a response, which will be comforting to both surgeon and patient. Beginning faradic response is the invariable harbinger of returning voluntary and emotional response in the muscles.

The Graft.—For the nerve graft any motor or sensory nerve will do. I have found the anterior femoral cutaneous nerve most satisfactory. It can always be found even through a deep layer of fat. A long transverse incision is made four or five inches below the fold of the groin, down to the fascia lata over the sartorius muscle. The internal saphenous vein comes into view: from a half-inch to one and a half inches external to this, two branches of the anterior femoral cutaneous nerve pierce the fascia lata over the sartorius and run down the thigh. Either branch will furnish any desired length of graft. I have used as much as 200 mm. from one branch. The selected branch is rendered easy of later identification by a suture of heavy black silk, the ends of which are laid in the subcutaneous tissues perpendicular to the skin wound. The nerve is cut and further identified for subsequent dissection by a narrow strip of dental gold wound around the cut end of the distal segment. It is essential that the nerve should not be disturbed in its bed, otherwise Wallerian degeneration may not be complete. I often reject the first 10 or 15 mm. below the cut end for this reason. At the second operation, when the degenerated

nerve is removed for graft material, it is well to take two or three times the measured distance of the gap. You may make a mistake with the first piece or you may decide to employ two or three strands. The nerve once cut is very difficult to find again. Having all you may want may save you much time in an operation which at best is very long.

The graft should be handled with the utmost gentleness by fine mouse-toothed forceps grasping only the sheath. Squeezing with blunt forceps or other instruments crushes the delicate empty tubes.

Homoplastic Grafts

Owing to an influx of cases there were at the Manhattan Eye, Ear, and Throat Hospital at the same time twelve cases together in my clinic. With the thought of economizing time I determined to see if homoplastic grafts might not be successfully employed. Dr. Eggston, the hospital pathologist, advised that grafts from persons having the same blood group only be attempted, on the principle that homoplastic skin grafts taken from individuals of the same blood group are more successful.

Accordingly, all patients were "grouped." One patient in whom the nerve had undergone preliminary incision and degeneration was found to be of the same group as two others. Grafts from the nerve of this individual were used for all three. The grafts were successful in all of the three cases. Figs. 5 and 6 show recovery following the use of a graft taken from an elderly woman and implanted into a man of the same blood grouping. I have since successfully employed homoplastic grafts in three other cases.

The necessity for the use of homoplastic grafts in repair of the facial nerve may be a rare occurrence. The demonstration of the fact that long grafts caused to degenerate *in situ* rapidly restored function to muscles may be of some importance in peripheral neural surgery, particularly if there comes another cataclysm like the recent Great War.

Conclusion

Tello, in Cajal's work, *Degeneration and Regeneration in the Nervous System*, has shown by physiological experiment the value of degenerated nerve grafts. I hope I have demonstrated their practical application to peripheral nerve surgery. I wish finally to urge upon you the great advantage of immediate investigation of the site of accidental injury in a case of facial palsy. In many instances the removal of a spicule of bone, the lifting of a fractured plate of bone, the decompression and cleansing of ten or more millimetres of nerve with a slitting of the sheath to relieve inflammatory pressure, will ensure an almost perfect recovery, where neglect would be followed by only partial recovery, with grotesque disfigurement for life (see Figs. 7 and 8 on Special Plate).

Moreover, when such an investigation reveals the fact that there is an actual section of the nerve or extensive damage, one can immediately do the preliminary incision of the femoral cutaneous nerve, and, two or three weeks later, transplant a graft from this to replace the gap. In such a case, for forty-eight to seventy-two hours after the initial injury one will have the advantage of being able to pick up the distal segment and verify it by faradic stimulation, and will know something of the problem to be faced in making the transplant later on. No matter what the length of graft necessary in such cases, one may rest assured of recovery if the graft is transplanted successfully, and to do this is a matter of technique (see Figs. 9 and 10 on Special Plate).

The question always arises: "When are we justified in operating on cases of long standing?" I would say: "Operate on any case in which there is galvanic response in the muscles sufficient to show that the muscles have not

undergone too much fibrous atrophy. The nerve can always be repaired. If there is sufficient muscle fibre left the case will be greatly improved. I am sure the quality of the result will always depend on the condition of the muscle: the time element enters largely into this.

LECTURE II—BELL'S PALSY

In my opinion Bell's palsy presents a condition analogous to the palsy of a facial nerve following injury during operation or following local necrosis and infection. In Bell's palsy toxic products are carried by the blood stream to the sheath of a nerve, confined in a narrow bony tube: a swelling ensues locally. Pressure on the axons produces a palsy of the facial muscles. It may produce pain, herpes oticus, or loss of taste, depending on the position of the inflammatory swelling. Now in the purulent cases from local infection, as well as in the injury cases, where the sheath is directly injured or compressed, the resulting palsy of the face is not due to the presence of pus *per se*, but rather to the inflammatory swelling and consequent mechanical pressure on the confined axons.

If the compression is severe enough, and lasts sufficiently long, the axons will be choked out of existence, and Wallerian degeneration will take place in the nerve distal to that point. If the compression is slight the axons may undergo only a paresis (just as one's arm or leg may "go to sleep" from a cramped position). In this case, although there may be a temporary loss of function, recovery will take place without any degeneration of the nerve cells or fibres. The electrical reaction of degeneration will not occur: faradic response will not be lost. Now if the opportunity were presented of carefully following every case of restoration of function in toxic palsy of the face, I am convinced that these varying degrees of compression would invariably be manifest in the electrical reactions. The idea that every case of Bell's palsy passes through the typical electrical reactions of Wallerian degeneration, either rapidly or slowly, is, I believe, erroneous. On the contrary, I feel certain there are many cases in which Wallerian degeneration does not occur. The axons in the nerve fibres become functionally sluggish or inactive, just as they might from a local anaesthetic, and recover without being degenerated, removed, and replaced. Just what percentage of all cases this type represents has never been determined. A more careful observation of all cases, at their inception, is most essential. It seems evident that early complete loss of faradic response is rare.

In a general way, without accurate statistics, one might infer from reports that of all cases perhaps 80 or 85 per cent. fully recover. I venture the conjecture that a majority of these milder cases never undergo Wallerian degeneration.

The remaining 15 or 20 per cent., I fancy, undergo a violent toxic infection with a severe inflammatory reaction (a compression within the Fallopian aqueduct), which renders the axons useless: in a day or two faradic response disappears. In such cases the regeneration is never complete. The facial movements may be entirely lost for all time, or may make some degree of recovery. The amount of recovery always bears a definite relation to the severity of the initial invasion. The relation of cause and effect in Bell's palsy is quite analogous to that in the accidental cases.

Incision of the Nerve Sheath

I attempted in the first lecture to point out that early intervention, no matter how violent the infection, is likely to lead to a nearly perfect recovery. Why not, then, apply this principle to the violent cases of Bell's palsy? Theoretically, leaving them alone is sure to be

followed by an incomplete recovery, with a grotesque appearance for life. Early operation might ensure almost complete return of function even in the cases of most violent invasion. It requires only some accurate means of knowing which cases will recover, and which will not recover, without surgical intervention. I believe that more careful study of the electrical reactions in all cases will eventually enable us to say, at a much earlier stage, that in such-and-such a case, left alone, the recovery will never be complete, whereas if operated on it might probably make a complete recovery. The earlier this determination can be made the better the chance of perfect movements of the face following intervention.

While I was discussing this with Sir Charles Ballance during the earlier years in which we were carrying out the animal experimentations, he repeatedly said: "The cases of Bell's palsy which make a partial recovery and then go on without any further improvement for weeks or months ought to have the nerve in the Fallopian aqueduct uncovered early and be decompressed by incision of the sheath, to relieve the pressure, at that stage. Such cases (unless they are appropriately treated) in all probability will go through life with a grotesque deformity." In principle I thoroughly agreed with this opinion. I realized, however, that there is great difficulty in convincing those who first come in contact with these cases that this is sound judgement. The trouble is that those who first see and treat cases of Bell's palsy are very loath to subject them to such a radical procedure as that of uncovering the nerve and incising the sheath, in the hope that the recovery will be sufficiently good to warrant it. The thought of subjecting a nerve to a trauma similar to that which is actually the cause of so many palsies of the face, at a stage when partial recovery has already taken place, is too appalling. Hoping that I might correct what I thought to be an erroneous belief, I tried a series of experiments on rhesus monkeys, in which I uncovered the nerve and incised the sheath.

Ten monkeys on which I incised the sheath of the nerve over an area of 10 to 15 mm. were examined daily afterwards over a long period. Nine of the ten suffered no facial paralysis, no Wallerian degeneration, no loss of faradic response. One of them gradually lost faradic response so that there was evidence of complete Wallerian degeneration at the end of nine days. Seventeen days later, however, faradic response began again, and in six weeks the face had apparently recovered. This case, undoubtedly, had suffered an injury to the axons, or had undergone a slight infection. However, he recovered quite as rapidly as any complete case of Bell's palsy. The other nine seem to prove that the actual trauma caused by incising the sheath, when carefully done, does not cause facial palsy.

I then induced facial palsy on a series of monkeys by exposing and freezing the nerve with ethyl chloride. One case was left without incising the sheath. On all the other cases the nerve sheath was incised over the frozen area, and a few millimetres distal and proximal to that area. The cases on which the nerve sheath was incised recovered facial movements in one-half the time required for recovery in the other cases.

The same experiment was made on a series of monkeys in whom facial palsy had been induced by the injection of 90 per cent. alcohol into the nerve sheath. The cases in which the nerve sheath was incised over the area of toxic involvement recovered twice as rapidly as those in which the sheath was not incised.

Clinical Results

Fortified by this experience I was sufficiently encouraged to incise the sheath of the nerves of several cases of Bell's palsy in which the recovery was very incomplete, and had remained unchanged for many years. In every instance, despite this long period of inactivity, the relief of the pressure by incising the sheath of the nerve has

resulted in a very marked improvement. May I give some examples from recent experience?

Case 1.—Miss M., a graduate nurse, appeared at my surgery. She had retired the previous night feeling quite well. She awakened with a complete right facial palsy. Under the pretext of electrical treatments she was seen daily. She never lost her faradic response in the facial muscles, although there were no spontaneous movements for more than a fortnight. At the end of a month she was apparently entirely well. Here is a case with no electrical reaction of Wallerian degeneration of the nerve, despite the fact that there was complete loss of facial movements for a time. This is a perfect example of the type where recovery is complete. I fancy that a very large percentage of Bell's palsy cases are of this type.

Case 2.—Miss D., two years ago, suffered an attack of Bell's palsy, recovering completely in four weeks in practically the same manner as the case I have just recorded. While I did not see her, I fancy she was like the first—a mild attack without Wallerian degeneration. She now appears with a complete palsy on the same side, which has lasted six weeks without any apparent improvement. The electrical reactions of Wallerian degeneration are present. On the ninth week from the onset, conditions remaining the same, at her insistence that something be done, I uncovered the nerve, by the removal of the external wall of the Fallopian canal from the stylo-mastoid foramen to the level of the horizontal semicircular canal, and gently incised the sheath over this area with the sharpest of Graefe knives. In one week faradic response had returned in all facial muscles. The second picture, two months later, shows an apparently complete recovery. Had she gone on for months before operation I believe she would have made only a partial recovery with marked disfigurement for life, as happens in most of these severe cases (see Figs. 11 and 12 on Special Plate).

Case 3.—Mrs. C. Bell's palsy two years ago. After several months some motion began in the face. She now has a return of function roughly estimated at 50 per cent., accompanied by a spasmodic tic in the lower part of the face. The aqueduct was opened, from the stylo-mastoid foramen to the level of the horizontal semicircular canal. The sheath was gently incised over this area. It was thickened with scar tissue. A small strand of nerve fibres traversed the area. They were not disturbed. A strand of degenerated anterior femoral cutaneous nerve was laid on this, extending from the proximal segment above to the distal segment peripheral to this area. In one month she declared that she felt much more power in her face, and the mouth was straighter in repose.

Case 4.—Miss S. Right Bell's palsy ten years ago, followed in a few months by partial recovery. Left Bell's palsy six months ago, followed by partial recovery. Recurrent attack on right side, causing complete palsy of the already partially paralysed side. At operation a double decompression by removal of the outer wall of the aqueduct from the stylo-mastoid foramen to the level of the horizontal semicircular canal was carried out. The nerve sheaths were incised over this area. Recovery of equal synchronous movements of both sides of the face, voluntary and emotional control, took place. The result is not perfect by any means, yet the girl has been rescued from social ostracism. This case was figured in my paper in the *Archives of Otolaryngology* (1932, xvi, 773).

I have also two cases of decompression of more than twenty years' standing, both of which, despite the long period, show a distinct improvement of facial movements.

Conclusion

May I say, in conclusion, that the principles of operative treatment of facial palsy, by direct repair of the injured nerve, have been well verified by clinical experience. I believe that, although operative treatment of the severe cases of Bell's palsy is not yet a fixed principle, with continued study of indications for early intervention it will eventually become so. If this should happen, many of the 15 or 20 per cent. of severe cases which are now doomed to go through life with a grotesque disfigurement will be cured by early operation.

THE STOMACH AND DUODENUM AFTER OPERATION*

43

S. COCHRANE SHANKS, M.D.

ASSISTANT RADIOLOGIST, CHARING CROSS HOSPITAL

(With Special Plate)

X-ray examination of the stomach or duodenum which has been the seat of surgical intervention often presents a problem of great difficulty. In the case of the intact stomach the examination is made easy because of the possibility of filling it out to its normal contour. As a rule, however, with the stomach after operation this is not possible, and a wide variety of appearances may present themselves in the absence of any pathological condition. It is the difficulty of disentangling these normal variations from the pathological which constitutes the problem.

Because of the above consideration the radiographic technique must be modified in some respects. Screen examination is even more important than in the intact stomach, and the demonstration of the mucosal relief pattern is of greater value. The technique must be varied according to the precise operation performed, and it is most desirable to have this information before commencing the examination.

A Radiographic Classification

From a radiographic point of view these cases fall into broad classes—those in which sphincteric control of gastric evacuation has been abolished, and those in which it has been retained. Some operations fall between these two groups, as follows:

1. Sphincteric Control Retained.

- Simple excision or cauterization of a gastric ulcer.
- Wedge resection.
- Sleeve resection.
- Gastro-gastrostomy.
- Duodeno-jejunostomy.

2. Sphincteric Control Partly Retained.

Pyloroplasty.
Schoemaker's operation.
Billroth I.

Although in all these the muscular pyloric sphincter is either cut or removed, yet enough control of efflux is exhibited by the stomach to warrant the above term in classification.

3. Sphincteric Control Abolished.

Gastro-jejunostomy. (Only when abnormal contracture of the stoma has taken place does there occur any degree of control.)

Billroth II.
Polya and its modifications.
Finney's pyloroplasty.

In the first group, with retention of sphincteric control, the technique should be the same as for the intact stomach. Special attention should, however, be paid to the relief pattern, both under the screen and in serial radiograms. The erect, supine, and prone positions are all of value, and the most suitable for taking radiograms will be determined by the fluoroscopic appearances.

In the second group, where partial control has been established, again the normal technique may suffice, but means should be at hand to control the gastric efflux should this prove to be too rapid to allow satisfactory and complete filling of the stomach. Such means are indicated in the succeeding paragraphs.

* Read in opening a discussion in the Section of Radiology and Electrotherapeutics at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

It is in the third group, with abolition of sphincteric control, that most difficulty occurs. A wide communication exists between the lower part of the stomach and the small intestine, and the gastric contents are rapidly poured out into the jejunum. It is impossible to distend the stomach, or stump of the stomach in gastrectomy, unless the efferent jejunal loop be occluded by pressure. This can be done by hand temporarily under the screen, but this immobilizes the palpating hand, and cannot be kept up indefinitely. Some form of mechanical compressor or truss is much to be preferred.

Mechanical Compressors

A well-known type is the Chaoul compressor. In this a metal ring, 5 inches in diameter, supports a rubber bag, which can be inflated to a hemisphere. It is strapped to the patient's abdomen by an attached broad webbing band and buckle. Pressure on the required area is induced and maintained by the inward bulge of the bag. The objections to it are the difficulty of precise adjustment and the shadow of the metal ring.

Overend has devised an ingenious pressure cone and serial radiographic apparatus for attachment to the screen-holder of an upright stand. Designed primarily to study the relief mucosal pattern of stomach and duodenum, it will serve to control the stoma of a gastro-jejunostomy. Its disadvantage for the latter is the small aperture it possesses, limiting the fluoroscopic and radiographic field.

I have designed an adjustable truss which answers the latter purpose—control of the efferent loop—satisfactorily. It consists of two portions—a leather-covered spring band, similar to that of an ordinary hernia truss, and an adjustable compression pad. Three or more spring bands are necessary, to fit varying sizes of patients. The adjustable pad comprises a base slotted for the reception of one end of the appropriate spring band, an arm hinged on this base giving,

FIG 1.—Truss compressor.

by means of a small thumbscrew and worm-gear, an anterior and posterior angulation, and a leather-padded aluminium pad. The arm is slotted throughout its length, and the pad can be adjusted along its length by a butterfly-nut. The hinged arm has an upward bend, so that the compression pad is above the level of the spring band when fitted to the patient. This avoids obscuration of the field under examination by the shadow of the spring. Reference to the diagram will indicate the details of the truss. (Fig. 1.)

Examination of Group 3 Cases

The technique for each individual case will vary according to circumstances, but that which I use as a basis is as follows:

The examination is commenced in the erect position, and under fluoroscopic control the patient drinks one mouthful of the opaque cream. This gives a preliminary screen survey of the relief pattern of the stomach, the stomach, and the efficient loop. The truss is then fitted with the spring band just below the iliac crests and the pad over the efficient loop. The patient drinks a few more mouthfuls, and the pressure of the pad is increased by turning the worm-gear. The obstruction of the loop is obtained. Sufficient of the fluid is then drunk to distend the stomach.

Antero-posterior, serial, and left lateral radiograms are now taken and the compressor removed. Removal of the latter is a matter of a few seconds. The rate of emptying of the stomach is then noted fluoroscopically, attention being paid to any tender points over the stomach, duodenum, and stoma. The degree of jejunal overloading, if any, should be noted.

In a minute or two the stomach will, as a rule, have largely emptied itself, and enough of the cream will remain therein to permit a further observance of the mucosal relief pattern in the prone and supine positions. Radiograms may be taken in these positions if necessary.

The patient should again be screened, half or one hour later, to determine the amount of residue in the stomach.

Such is the average technique required in these Group 3 cases, but the study of each case should be individual, and no cast-iron routine should be adopted.

Before considering the normal and pathological appearances after operation it is desirable to outline the nature of each. Some of the operations mentioned above are but rarely performed, and still less frequently seen in an x-ray department. For reasons of space these infrequent operations, which have now little more than a historic interest, will not be considered further. Others, such as posterior gastro-jejunostomy and partial gastrectomy, are *très à la mode*, and such patients are frequently referred for x-ray investigation.

The group with abolished sphincteric control comprises the majority of operation cases referred for x-ray examination, including as it does gastro-jejunostomy and the popular varieties of gastrectomy. Incidentally, it is the most difficult group to examine radiographically.

Gastro-jejunostomy Cases

Posterior No-loop Method.—This is the operation of choice for simple pyloric obstruction and duodenal ulcer, and is probably performed more often than all the other gastric operations together. The essence of it is to form a wide anastomotic opening between the jejunum, as close to the duodeno-jejunal flexure as possible, and the posterior wall of the stomach. The anastomosis must of necessity be made through the posterior layer of the lesser sac. The pylorus is sometimes occluded; this occlusion is often designed to be temporary; by suitable choice of sutures the pylorus will become patent again in six months after the operation. The objects of the operation are to provide free drainage of the stomach, to allow alkaline regurgitation from the jejunum, and to prevent the passage of acid gastric contents over the pyloric or duodenal ulcer.

FIG. 2.—Posterior gastro-jejunostomy.

(Fig. 2.)

Normal Radiographic Appearances

In the erect position the prominent feature is the immediate passage of the opaque medium into the jejunum. This occurs as soon as the patient swallows a mouthful or so. No more should be given in the first instance, as the initial study of the relief pattern of the stomach, stoma, and jejunum is important. If the patient then takes the remainder of a 12 to 14 oz. barium meal some fleeting filling of the stomach may take place, but more commonly an irregular partial filling only is achieved, the barium pouring into the efferent loop of the jejunum in a steady stream. The greater curve above the stoma is markedly indented by the mucosal folds. The latter results from the muscular contractility of the stomach. During this stage the stoma itself is hidden in the antero-posterior view.

The pyloric antrum, distal to the stoma, rarely fills to any extent, even if the pylorus has not been occluded

in a case of duodenal ulcer. As a rule, a few irregular streaks of barium are all that are seen in this portion. Exceptionally, it is better filled, and some of the barium cream passes through the pylorus and duodenum, but even then the pyloric antrum is conical, and lacks its normal rounded contours. If the pylorus has been occluded the filling of the pyloric antrum is very poor indeed. The stoma may be seen in profile in a lateral view, but for technical reasons it is generally difficult to obtain a sharp skiagram of it in this position.

The efferent jejunal loop and the coils of jejunum are usually somewhat distended with barium, and a mild permanent dilatation of the upper jejunum is normal. It may be considerable. The feathery appearance resulting from the valvulae conniventes persists, but to a less extent than in the normal, as a result of this dilatation.

As a rule none of the meal passes into the afferent loop via the stoma with the patient in the erect position. Any barium present in it and in the duodenum will have found its way through the pylorus.

The rate of emptying is remarkably rapid, in my experience. Various authorities have given the time for complete emptying as from one to two hours, and even more. These figures may be true if by "emptying" is meant the complete evacuation of every trace of barium from the stomach, but not if the main mass of barium is referred to. The main bulk of the opaque meal may have passed out into the jejunum in from ten to fifteen minutes, and yet traces of barium remain entangled in the mucosal folds for an hour or two (especially in the folds of the pyloric antrum). Disregarding these entangled residues, the stomach is empty in from seven to thirty minutes if the stoma be of average size. With a large stoma these limits are shortened, and with a small one they are increased.

The rate of emptying of the stomach is modified by posture. In the supine position a pool in the fundus may remain for a time, being there below the level of the stoma. No lengthy stasis occurs, however, as the contractile tonus of the stomach gradually empties it. As the stomach empties its contents, the mucosal pattern of and around the stoma again makes its appearance, and may again be studied fluoroscopically. Tenderness on pressure over the stoma and elsewhere is an important diagnostic feature, and careful search for such tender points should always be made.

If the stomach before the operation was grossly dilated and atonic, and its muscle coats too atrophied to be restored to the normal, the radiographic picture after gastro-jejunostomy will be somewhat modified. Some dilatation will remain, the indentations of the greater curve will be less, and there will be a tendency to pool formation in the pyloric antrum below the stoma. The main mass of the barium cream will, however, pass rapidly into the jejunum.

Pressure Control of the Efferent Loop

It is obvious from the normal appearances without control that the demonstration of recurrent duodenal, pyloric, or lesser curve ulcer may be difficult on account of incomplete filling of the stomach. Efficient obstruction of this loop enables the contrast medium to be dammed back in the stomach and a study of these portions to be made.

Using an apparatus such as is described above, the lesser curve can be examined in its entirety. The prepyloric region is sometimes filled to its normal contours, but more frequently remains to some degree contracted and conical. If the pyloric canal be not obstructed or occluded the meal can be forced through it into the duodenal bulb. It is of importance here to know beforehand whether the pylorus was occluded at the operation

or whether it was already stenosed. The duodenal bulb does not usually fill out to normal contours, partly because it is difficult to force a sufficiently large amount of barium through the pylorus at a time, and partly because some scarring of the bulb may persist after the healing of a duodenal ulcer.

Complications after Posterior Gastro-jejunostomy

Ryle has grouped the complications after gastro-jejunostomy and partial gastrectomy as follows, in ascending order of gravity:

1. Dumping stoma.
2. Vicious cycle.
3. Perianastomotic gastritis and its ulcerative complications.
4. Achylic anaemia.

Groups 2 and 3 tend to be intermingled in actual practice, vicious cycle often being the result of an ulceration and cicatrization falling into Group 3. Again, Ryle's grouping does not include recurrent ulceration of the lesser curve or duodenum, or gastric carcinoma. With the exception of achylic anaemia, these complications can usually be demonstrated radiographically.

Jejunal Dumping (overloading of the jejunal loop).—If the stoma be very large the flooding of the jejunum is exaggerated, and the stomach may empty into it in from two to three minutes. The patient experiences a dragging fullness and discomfort immediately after food, and the jejunum is seen to be distended and overloaded temporarily. Dietetic indiscretions, either of quality or of quantity, increase the patient's discomfort. It is reasonable to explain the symptom-complex on these mechanical grounds. To what extent jejunal overloading contributes to the development of jejunal ulcer is a moot point, and one difficult to put to the test. Possibly if much gastric hyperacidity be present it may have some effect.

Recurrent Ulceration.—This may be gastric, pyloric, duodenal, gastro-jejunal, or jejunal in site.

1. **Recurrent lesser curve ulcer** is, as a rule, easily demonstrated if the stomach be reasonably well filled by controlling the efferent loop. A niche will be visible, and on the greater curve a localized exaggeration of the notching which is usually present.

2. **Recurrent duodenal ulcer** presents a more difficult problem—even more difficult than in the case of a duodenal ulcer which has recurred after medical treatment. In the latter only the deformity due to scarring has to be discounted. After jejunostomy, however, the further disturbing factor of incomplete filling of the cap must be taken into account. In some cases the actual ulcer crater may be seen, but more frequently only some general deformity of the duodenal bulb is present. If the jejunum has been satisfactorily occluded by a truss, and food is passing freely through the pylorus, the second disturbing factor can be excluded, and the problem becomes that already described under the section of duodenal ulcer.

3. **Gastro-jejunal Ulcer.**—As the stoma on the posterior wall is hidden in the antero-posterior view an ulcer will show only in a relief pattern radiogram. If it be large it may be visible in profile in a lateral view. Owing to the normal irregularity in the contours in a healthy stoma care must be used in diagnosing an ulcer crater from a projection above. Further confirmatory signs may help. The most important of these is pain on pressure, localized over the stoma. In the present state of our technique persistent tenderness on pressure is probably the most reliable sign of a stomal or jejunal ulcer. Another sign of value is a persistent residue in the ulcer crater. Such a residue must, however, be differentiated from flecks

entangled in the mucosal folds in this region. An ulcer situated in the region of the stoma may, by spasm plus scarring, cause stenosis of the stoma itself, with gastric stasis; stenosis of the opening of the proximal loop, with the development of duodenal ileus if the pylorus is patent; or stenosis of the distal loop, again causing duodenal ileus, if the proximal be patent.

4. **Jejunal Ulcer.**—If this be close to the stoma the above remarks will apply. If it occurs below the level of the greater curve there is more chance of the ulcer crater being outlined at some stage of the examination. Again care must be taken not to mistake a fleck of barium entangled in the mucosa for a barium-filled crater. The larger, the denser, and the more persistent a residue, the more likely it is to be an ulcer crater. Localized tenderness to pressure of one finger over the residue is an important confirmatory sign. The valvulae conniventes seen in relief pattern converge to, and are interrupted by, the crater, an appearance best seen if the latter is on the anterior or posterior wall, and so viewed *en face*. Some spastic contraction of the circular fibres in the ulcerated segment may occur and be visible.

Jejunitis.—Occasionally the valvulae conniventes of the efferent loop are thickened and their feathery character lost—an indication of a jejunitis.

Narrowing of the Stoma.—The usual surgical practice nowadays is to make a wide stoma to allow for gradual contraction. If this contraction is greater than usual the rate of gastric evacuation is slowed. To what extent this narrowing and consequent slowing is disadvantageous is a matter of doubt. The wide stoma, while it achieves its results so far as drainage is concerned, alters the normal physiological processes profoundly, and frequently causes jejunal overloading. Narrowing of the stoma sufficient to slow the rate of emptying of the stomach to between one and one and a half hours is probably not undesirable, but retention in the stomach up to two, three, or more hours should be regarded as a sequela likely to defeat the objects of the operation. In such cases the stenosis of the stoma cannot be demonstrated directly. Its presence can be deduced only by the slow rate of emptying.

Malposition of the Stoma.—If the stoma be made too high, stasis of gastric secretion may occur in the part pyloric, in the erect position, and be a factor in the recurrence or persistence of a peptic ulcer. The position of the stoma can be accurately demonstrated in a lateral view or a relief antero-posterior one.

Duodenal Ileus.—This, too, may result in a minor degree from a high stoma, especially if a visceroptosis of some degree be present. In such case, if the duodenum and duodeno-jejunal flexure be poised below the level of the stoma, the stomach may empty itself partly into the efferent jejunal loop, and so into the duodenum. This sequence of events is visible fluoroscopically. On the patient swallowing a mouthful of barium some is seen to pass into each loop of the jejunum, that going into the afferent collecting in a pool in the dependent part of the dilated duodenum. This is seen only in the erect position. The supine or prone position removes the static factor which is the essence of the abnormality. Duodeno-jejunostomy is the appropriate treatment.

Anterior Gastro-jejunostomy

In this a long loop of jejunum is brought up in front of the transverse colon and anastomosed to the anterior gastric wall. It is performed, *faute de mieux*, when a gastro-enterostomy is essential and it is technically impossible to adopt the posterior method. The stoma is made as near as possible to the pylorus and greater curve, and its axis should run from above downward and to the

right. Because of the serious risk of stasis in the long afferent loop, about eighteen inches in length as a rule, an additional jejunostomy is frequently made between the two loops. (Fig. 3.)

FIG. 3.—Anterior gastro-jejunostomy.

The x-ray appearances in anterior gastro-jejunostomy are substantially the same as those in the posterior operation, except that in the lateral view the stoma and jejunal loop are visible anterior to the stomach, and two jejunal limbs, afferent and efferent, are often outlined below the stomach. If the operation be successful, only the efferent loop should fill, but frequently food also passes into the afferent. When this occurs to excess a vicious circle is established, and the dilated, overloaded proximal loop is at once apparent radiographically. Jejunostomy completely relieves the condition.

The other untoward sequelae of anterior gastro-jejunostomy are similar to those in the posterior method.

Billroth II Partial Gastrectomy

In the past a popular operation for carcinoma of the stomach, or large chronic ulcers in the region of the lesser curve, this is to some extent being superseded by the Polya types of gastrectomy. It consists of segmental resection of the stomach, including the pyloric canal, closure of both ends, and posterior gastro-jejunostomy. (Fig. 4.)

FIG. 4.—Billroth II.

Radiographically the stomach behaves similarly to the jejunostomized stomach, save that the pyloric antrum is absent. At first the gastric stump is small, but later it enlarges somewhat. This dilatation is not marked unless contracture of the stoma takes place. The right blind extremity of the stomach assumes a rounded, slightly puckered contour. The stump can best be seen if the efferent jejunal loop be obstructed by a truss. Only then can the stump be properly filled and its contours studied.

Normally there is no reflux from the stomach into the afferent loop and duodenum. But efficient obstruction, by a truss, of the efferent loop will cause such reflux, an appearance which must not be mistaken for a vicious circle. It disappears on removal of the truss.

After-results

Recurrent gastric, stomal, or jejunal ulcer is less common than in gastro-jejunostomy, as a considerable proportion of the acid-producing mucosa is removed by the operation. The more complete the gastrectomy the less chance of recurrent peptic ulcer. As, however, this operation does not allow of a very wide resection, recurrent ulceration does occasionally occur, and its radiographic demonstration and appearances are similar to those in gastro-jejunostomy.

In cases of carcinoma ventriculi local recurrence of the growth is not uncommonly met with. Depending on the precise site of the recurrence, there may result:

1. Obstruction of the whole stoma.—This causes dilatation of the fundus and oesophagus, and, clinically, vomiting and rapid starvation. The nature of the condition is clearly visible on fluoroscopy, and the details of the gastric filling defect in serial radiograms. Discounting the distortion, due to the suture line, a recurrence causing the above interference with the stoma usually presents a constant filling defect, which is fairly characteristic.

2. Obstruction of the efferent loop alone.—The stomach will present similar appearances, but in addition the duodenum will be in a state of ileus, and be outlined by the barium cream passing from the afferent limb into it.

3. Obstruction of the afferent loop alone.—Again a duodenal ileus results, but as no barium can pass into it, it will be demonstrable radiographically only if it contains gas.

The Polya Operation

Polya-Moynihan.—This modification of the original Polya operation is probably more frequently adopted in this country than any other form of partial gastrectomy. It consists of a segmental resection of the lesion-bearing portion of the stomach, including the pylorus, as in the Billroth II, with end-to-side anastomosis of the gastric stump to a loop of jejunum. In the original Polya the jejunum was brought up through a fenestra in the transverse mesocolon. This has the disadvantage, in cases of carcinoma, that a recurrence, apt to take place near the fenestra, may cause obstruction of the jejunum. This is avoided by the Moynihan modification, in which a loop of jejunum is carried up in front of the transverse colon. The diagram indicates the direction of the jejunal current (from left

FIG. 5.—Polya-Moynihan.

to right). The loop is chosen as near to the duodeno-jejunal flexure as possible, allowing enough length in the afferent limb to prevent any possibility of tension on it when the patient assumes the erect position. (Fig. 5.)

Polya-Balfour Operation.—In Balfour's modification the long jejunal loop is used, and the jejunal current is in the

FIG. 6.—Polya-Balfour.

reverse direction to that in the Polya-Moynihan operation. In order to prevent stasis in the proximal limb a lateral anastomosis is made between the two limbs of the loop. (Fig. 6.)

Modified Polya, with entero-anastomosis en Y.—In this modification a segmental resection is made as before. A jejunal loop is brought up as in the Polya-Balfour, but is divided across. The cut end of the distal limb is closed

FIG. 7.—Modified Polya: anastomosis en Y.

and that limb anastomosed side-to-end with the gastric stump. The proximal jejunal limb is then anastomosed end-to-side with the distal limb an inch or two below the gastric anastomosis. (Fig. 7.)

Polya: Lake's Modification.—This modification, judging by the radiographic appearance, controls the efflux of the gastric contents better than any other of the Polya type. In addition to preventing "dumping" into the jejunum, it renders reflux into the afferent loop very improbable. In it a short jejunal loop is brought up through the

FIG. 8.—Polya: Lake's modification.

transverse mesocolon, the jejunal current flowing from right to left. Although the jejunal loop is sutured along the whole length of the cut gastric stump, only a small stoma, about $1\frac{1}{2}$ inches in length, is made at the lower end. (Fig. 8.)

X-Ray Appearances in Polya-Moynihan Type of Partial Gastrectomy

With the Polya-Moynihan the gastric stump is, as a rule, smaller than in the Billroth II operation, and the anastomosis is seen to be terminal. To study the full contours of the stump control of the efferent loop will be necessary, but this should be preceded by observation of the normal emptying (that is, without control). Under the screen careful note should be made of the efflux into the jejunum. The barium should be seen to pass chiefly into the efferent limb, at the right of the stump. Some will pass into the left, or afferent limb, but this should not be excessive.

With control of the efferent limb the fundus of the stomach should fill out to a normal contour, and there may be some oesophageal reflux. The afferent jejunal limb will fill more definitely, and active peristalsis will be seen as this loop endeavours to empty itself. The contours in the region of the anastomosis vary considerably, depending on the precise position of the sutures. A certain amount of puckering is to be expected.

The stomach, after this operation, empties very rapidly: by the time the patient has finished drinking a 12-oz. meal most of it will be in the jejunum, and mild jejunal overloading is a common effect of rapid ingestion. Occasionally it may be marked, causing a sensation of fullness and dragging in the abdomen. It is therefore important that a patient should masticate thoroughly, and eat and drink slowly, after having been subjected to this type of operation.

Abnormal After-results

Recurrent Peptic Ulcer.—This, an uncommon sequela, may be gastric, stomal, or jejunal in site. The more complete the gastrectomy the rarer is such a complication. Recurrent gastric ulcer may be on the lesser curve, when it will show as a niche, or on the posterior wall. In the latter case a relief picture is the best means of demonstrating it. Stomal ulcer is more easily demonstrable after the Polya type of operation, as the stoma is terminal relative to the stomach. As with other forms of stoma, residues entangled in puckered mucosa must be differentiated from a barium-filled ulcer crater. The latter are more constant in a series of pictures, and, if the ulcer be deep, denser from sedimentation therein. Tenderness on localized pressure over the suspected shadow is an important confirmatory sign. Jejunal ulcer is more readily visible than in cases of gastro-enterostomy, as the gastric shadow is not superimposed on the juxtastomal portion.

Overloading of the Proximal Limb.—This rarely occurs in the Polya-Moynihan operation if the afferent jejunal limb be short and the axis of the stoma properly planned, but with a vertically disposed stoma and an unduly long limb some stasis and ileus may be seen. It does, however, occur in:

Recurrent carcinoma, if the efferent limb be obstructed by the recurrence. Clinically, such cases present characteristic features—inability to eat or drink any but small amounts, persistent vomiting, epigastric pain, and wasting. Radiographically, a gastric filling defect near the efferent stoma may be present. Oesophageal reflux and dilatation may occur, and the meal is seen to distend the afferent limb. The rate of gastric evacuation is slow, unless by vomiting. Recurrent carcinoma of the gastric stump itself is apt to cause stenosis at or just above the stoma. Clinically the symptoms are as above described, and radiographically a considerable filling defect of the stump will be apparent. Scarring from recurrent simple ulceration may also cause obstruction of either stoma—efferent or afferent—with similar appearances to those in the carcinomatous variety, save there will not be present a gross filling defect of the stump itself.

X-Ray Appearances in Polya-Balfour, Polya-en-Y, and Polya-Lake Operations

The appearances will vary from those above described chiefly in the site of the efferent jejunal limb, which is situated at the left angle of the stump. In the Balfour modification some barium may pass into the afferent loop, but this can cause no trouble, because of the jejuno-jejunostomy below. In the en-Y type, again, no overloading of the afferent limb can occur. With these exceptions the abnormal after-effects are similar to those described in the case of the Polya-Moynihan.

In the Polya-Lake operation the gastric stump fills reasonably well in the erect position, and the stoma is clearly seen at the lower pole. The right border of the stump is formed by the remaining portion of the lesser curve and the sutured end of the stump above the stoma. This largely loses its initial angularity, and becomes more or less straightened out. At the junction of the two there is apt to remain a dimple, which must not be mistaken for a recurrent lesser curve ulcer.

Complete Gastrectomy

Complete gastrectomy (Moynihan) is a difficult operation technically, and attended by an appreciable immediate mortality. It is indicated in some cases of gross scirrhus carcinoma of the leather-bottle type. It consists of resection of the whole stomach, and end-in-side, or side-to-side, anastomosis of the lower end of the oesophagus with a high loop of jejunum. The latter is brought up through a fenestra in the transverse mesocolon. The two limbs of the jejunum may be anastomosed lower down to short-circuit the bile and pancreatic secretions.

X-Ray Appearances after Complete Gastrectomy

If examined a few weeks after operation the meal will be seen to pass rapidly down through the stoma into the coils of jejunum. Even at this stage there may be evident some dilatation of the jejunal loop close to the stoma.

Butler¹ has described the appearances in a case six months after complete gastrectomy. The feature in it was a considerable dilatation of the jejunum close to the oesophageal stoma. The dilated portion was ballooned into the left dome of the diaphragm, contained a gas bubble, and simulated the fundus of a normal stomach. Doubtless the constant upward pressure of gas in this loop contributed to this effect. Barium remained in this dilated pseudo-fundus for more than five minutes. At the end of an hour all the barium had accumulated in the pelvic coils of the ileum. Transit is therefore rapid, as in the partial gastrectomy cases.

THE RELATIVE ADVANTAGES OF BRITISH AND FOREIGN HEALTH RESORTS*

BY

E. P. POULTON, M.D., F.R.C.P.

PHYSICIAN, GUY'S HOSPITAL

The British Health Resorts Association broadly classifies health resorts into: (1) spas, (2) resorts at the seaside, and (3) resorts inland. In all cases climate must be considered important from the point of view of health, using the word climate in a wide sense to include not only the air with its temperature, moisture, and movement, but sunlight and more intangible influences which may arise from running water, vegetation, and animal life, and which affect our spirits as well as our bodies.† While inland health resorts rely entirely on these factors, those at the seaside and spas have the sea and natural waters as additional agents for the promotion of health.

In a comparison of British and foreign health resorts it is wise to consider the people who go to them. By far the largest number of visitors are the holiday makers,

who have no thought of health, but who look for a pleasant place with a "change of air" and plenty to do. With these people we are not concerned at all. A second group consists of those who, in the main, are out for a holiday, but who wish to take some medical treatment as well. For instance, the man who overeats all through the year takes a cure during his holiday in order to go through the round once again. These people have money to spare, and may prefer a foreign spa, since the change in their surroundings will be the greater. Nor can there be any objection, since this country receives numerous visitors from America, and America must receive an equivalent in imports and services from the Continent. It was quite different in 1932 when the British Health Resorts Association was founded; that was a time of temporary danger, and English people were asked to stay in their own country. A third group consists of those who visit a health resort purely for the sake of their health.

Health resorts, so far as they contain up-to-date installations, can provide all those general physical methods of treatment that can be obtained in London or in other large centres—for example, douches, steam and paraffin-wax baths, diathermy, etc. All the larger spas, British and foreign, are alike in this respect. In fact, until quite recently, these general methods of treatment were administered more effectively at a spa than in London, although there is no reason why this should have been the case, since all towns nowadays have water and an electricity supply.

Climate

Climate is generally described as "tonic" or "bracing," and on the other hand as "relaxing," or, if this word has unpleasant associations, as "sedative." From the point of view of clear thinking the use of these words might well be discontinued. A "bracing" climate can only mean a climate of marked cooling power. Leonard Hill's observations with his kata-thermometer show that cooling power depends on three factors: temperature, humidity, and the movement of air. Hence a bracing climate must mean one possessing a cool, dry, breezy atmosphere, while a relaxing atmosphere will be hot, moist, and still. British spas, with the possible exception of Bath, belong to the former category, and this is an advantage, because at the end of the cure the patient can go straight back to his ordinary occupation. The same is not the case with a relaxing climate. For instance, a patient of mine described a previous visit of hers to Salsomaggiore as extremely tiring, and she had to go to the mountains in Switzerland before returning to England; this is the "Nach-kur" of the Germans.

British seaside resorts have a wonderful variety of climate. In the South-West they approximate to the French and Italian Riviera, but as there are usually more clouds in the sky the fall in temperature at night is less marked; the days are not so hot and the nights are not so cold. The resorts in the East and North-West are cool, while those in the South-East may be regarded as intermediate. Full details are given in the handbook of the British Health Resorts Association.

Physiological Effects of Mountain Climate

England possesses no mountain climate, and if such is required patients must go to Switzerland, or further afield to the High Tatra in the Carpathians. It is claimed that clinically the moorland climate in the North is equivalent to a mountain climate. A valuable summary of the physiological effects of a mountain climate (not applicable to any English resort) was communicated by Professor A. Loewy to the International Society of Medical Hydrology at its annual meeting this year in Switzerland. The action of such a climate is due to the reduced

* Read in opening a discussion in the Section of Balneology and Climatology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

† It is advisable not to be too sceptical in these matters. I need only allude to the recent correspondence in *The Times* on water divining and on the important experiments carried out last year by Dr. Lintott in the Physiological Department of Guy's Hospital. He found that water running beneath the subject produced an increase of tone in the muscles with corresponding rise in the twig or other apparatus used; and that this effect was not abolished by electrical insulation of the body, but that it was necessary for the subject to throw the muscles of the arms and legs voluntarily into tension. Thus the results were not obtained when the subject walked on a smooth surface such as glass, since there was no purchase for the legs. May not these obscure influences have some medical bearing in the future? We read that water divining continued through the afternoon produced a headache!

pressure of oxygen, which appears to stimulate the production of adrenaline, causing a rise of blood sugar, an increase in the formed elements of the blood which are at first pressed out of the spleen; there is an increase of glutathione, the ferment first prepared *in vitro* by Sir Gowland Hopkins; and certain substances appear in the serum, known as haemopoietins, which have the property of hastening the regeneration of blood after haemorrhage. A point of some interest is the rise of serum calcium, which means that the sympathetic becomes less excitable and the thyroid less active. This fact was discovered empirically a number of years ago when an exophthalmic goitre patient, sent from Vienna to the High Tatras, did remarkably well; the mountain climate is now recognized to be of value in this disease, and insured patients are sent to the Tatras. No patient with cardiac insufficiency should be sent to the mountains; but it has long been known that patients with phthisis and surgical tuberculosis do well there. The deficiency of oxygen must clearly be a responsible factor, since among other things this stimulates the production of red cells and counteracts the anaemia.

What is meant by "fresh air" in the treatment of phthisis in this country? "Fresh air" does not mean air with an unusually large amount of oxygen in it, because the percentage of oxygen is much the same in the country as in the town. When animals are placed in oxygen the haemoglobin content of the blood diminishes, and oxygen in no way stops the tuberculous process when the animals have been infected with the disease. The Swiss climate is beneficial because the pressure of oxygen is below normal. "Fresh air" treatment of phthisis in this country must mean treatment by cold, since this has been found to increase the metabolism of the resting subject, and patients who live out of doors all the time have better appetites and eat more food to provide fuel for their increased metabolism. The three general factors in treatment that can be supplied by the tuberculosis sanatoria of this country are fresh air with its increased cooling power, rest, and good food. A fourth factor—diminished oxygen supply—is only present in the mountains. Sunlight is a fifth factor suitable for surgical tuberculosis, but this is not given in phthisis, since it causes haemoptysis from congestion of the lungs—at least, that is the Swiss experience.

Sea Bathing

Michelet, writing in 1861, said that the English doctor Richard Russell (1700-71) had "invented the sea." Russell noticed that the fisherfolk were free from scrofulosis; that the women had white teeth and hard gums, and were free from all putrid coughs and fluxions; and that children who came to the sea weak, wan, and too warmly wrapped up, were sent back to their parents after sea bathing "bare-necked, their hair shaved, and tumours of the neck cured and the countenance healthy." He remarked that the sea had great and varied excellencies, but it might be misapplied by unskilful persons. This pioneer work of Russell's was followed by that of Lettsom, the Quaker physician, who was responsible for the building at Margate of the Royal Sea Bathing Infirmary for the relief of the scrofulous poor of London and all England. The *Gentleman's Magazine* states that "the patients have medical assistance, and a bathing machine has been built for their sole use." The foundation stone was laid by Lettsom in 1792, in the presence of many rejoicing spectators. This early work has now spread round the world.

The most complete study of the effect of sea bathing on children has been made by Haeblerlin, and he himself addressed this Section a year or so ago. He, with Krauel,

studied the reaction of the rectal and skin temperatures to sea bathing and air baths. They found that the chest measurements and vital capacity increased much more quickly during the summer while at Wyk than during the rest of the year at home. There was an increase in the haemoglobin content of the blood, which fell during the rest of the year, and in the case of one boy observations were carried out through six successive years. There was a marked increase of weight, which took six weeks before it became constant. This work is an impressive performance, and it has only been possible to quote a few of the most striking results. On the face of it, it would seem that the seaside might vie with the mountains as a blood-regenerating agent. It would be most desirable that some enthusiastic observer should repeat similar measurements at an inland station, so that the merits of these two types of health resorts could be compared. A boy scout or girl guide camp would provide healthy subjects for study, especially if the camp went alternate years to the seaside and inland.

Our seaside health resorts are not charitable institutions, nor are they health stations conducted by the Ministry of Health with the taxpayers' money. They are largely run for the benefit of the ratepayers and the hotel proprietors, and the medical aspects of sea bathing often have to take second place to popular baths, sun bathing, sports, and carnivals, which will attract visitors in their thousands. But medical baths have been instituted recently at Hastings, and are available at other places. It is important that any municipality which intends to introduce such baths should put the plans before a medical advisory committee, and that the baths when instituted should be under some kind of medical supervision, and not left to the sole control of a bath master who has had a little technical training.

Spa Waters

Successful attempts have been made to demonstrate the specific biological action of certain natural waters and baths. Reference may be made to the late Professor Billard's observations on Vichy water, which have been described by Monod and Ferreyrolles, and to Baudisch's work on the ageing of waters carried out at the Saratoga Springs. Harpuder at Wiesbaden has recently shown that mineral-water baths containing 0.6 per cent. sodium chloride taken at an indifferent temperature produce biological effects that were not observed in controls, or when baths of tap-water were taken at the same temperature.

Natural Waters in England

In this country reference may be made to the well-known experiments of David Brown and Woodmansey on the Harrogate sulphur water, and those of Bain on a patient with a biliary fistula. Buxton water has been shown to produce a diuresis. The daily output of urine from a number of subjects was measured first of all on a controlled diet, then with the addition of a pint of tap-water, and finally the tap-water was replaced by Buxton water. I should feel happier in my own mind if these experiments could be repeated in a different order, with the Buxton water period before the tap-water, to make quite certain that the diuresis attributed to the Buxton water was not the result of the previous water-logging of the individuals.

Our lamented colleague Michael Foster published shortly before his death an excellent handbook on British and foreign spas.

It may be taken for granted that the use of natural waters will be promoted in proportion as research work of value is carried out in the locality; in fact, it is only necessary to attend the meetings of the International

Society of Medical Hydrology in order to realize that advance is being made over a wide front, and that in research this country is by no means behind. But this applies chiefly to the larger and more important spas. One of the difficulties is that in the smaller ones it is often not generally realized that the waters have valuable properties. For instance, it has been pointed out that the Pittville Spring in Cheltenham has practically the same composition as some of the Vichy springs. It would be expected that in a country like England, where all but a few geological formations are well represented, a great variety of waters would be encountered. There are, no doubt, more in existence than are used; but it must be admitted that this country is rather poorly supplied with thermal waters, Bath and Buxton being brilliant exceptions, and there is no water containing carbon dioxide.

Turning to the subject of muds, or peloids, as they are called in the new classification, there is plenty of peat and alluvial mud available, but there is no hot volcanic mud such as is found on the Continent. Another difficulty that the British spas have to contend with is that they are mostly residential towns, and the interests of the residents and of the medical men and hotel proprietors tend to be opposed. To have an up-to-date hydrological institution with medical baths it is necessary to spend money and so to increase the rates. This appeals to one section, but is not unnaturally opposed by the other.

Post-Graduate Teaching in Hydrology

Perhaps the main difficulty in the more widespread use of our natural resources at the seaside and inland lies in the lack of knowledge on the part of the average medical man in the locality as to what is possible with these newer methods of treatment and how to apply them. It should be the object of the Section in future years to remedy this deficiency. It would clearly be wrong to try and insert any teaching or examination on the special subject of medical hydrology into the undergraduate's medical curriculum. Already the latter is too full, and with the advance of general medical knowledge it is likely to become still more so. The best way would be to institute post-graduate teaching in this subject with a diploma at the end of the course. Many of the more specialized branches of medicine—for example, radiology—are served in this manner. Now would be a suitable time to introduce such a scheme, since the University of London, with the assistance of the Government and the London County Council, is about to open a new post-graduate college. These authorities should be urged to add a voluntary course of instruction in climatology and medical hydrology to the curriculum.

The Year Book of the Royal Society of Tropical Medicine and Hygiene contains the twenty-seventh annual report of the council, in which it is mentioned that the forthcoming volume of the *Transactions* will be seventy pages larger than its predecessor. An affiliation has been arranged with the Fellowship of Medicine whereby Fellows of the society are enabled to claim a useful reduction of fees for any of the Fellowship's post-graduate lectures and demonstrations. It is expected that this will prove useful to any Fellows of the society who are home from abroad on leave, and to any others who are visitors to London and desirous of bringing up to date their knowledge of some branch of medicine or surgery. The debt on Manson House is being decreased slowly. The Year Book also contains lists of Fellows alphabetically and geographically arranged, the accounts for the year, lists of papers and short communications published in the *Transactions*, and a directory of officers of the society, including local secretaries throughout the world.

MEDIASTINAL AND APICAL EMPYEMA

BY

STANLEY J. HARTFALL, B.Sc., M.D., M.R.C.P.

HONORARY PHYSICIAN, LEEDS PUBLIC DISPENSARY AND HOSPITAL;
LEVERHULME RESEARCH SCHOLAR, ROYAL COLLEGE OF
PHYSICIANS, LONDON

AND

LESLIE N. PYRAH, M.Sc., Ch.M., F.R.C.S.

HONORARY ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY;
HONORARY SURGEON, LEEDS PUBLIC DISPENSARY
AND HOSPITAL

(With Special Plate)

The combination of two encysted purulent effusions within one pleural sac is sufficiently rare to be worthy of record. In the case now to be reported two loculated empyemata occurred in the right chest, one in the right posterior sub-apical region, the other between the right side of the pericardium and the pericardial aspect of the right lung. The condition gave rise to considerable difficulty in diagnosis, even after an x-ray examination of the chest. The course of the case, which was stormy, is detailed below, but the patient eventually made a complete recovery. A series of antero-posterior radiograms illustrates the progress of the condition.

Case Report

H. D., male, aged 45. The patient had been vaguely unwell for some two or three weeks, but able to continue work. His present illness commenced suddenly, and appeared to be a typical right-sided lobar pneumonia with physical signs in the right chest; the temperature fell by lysis on the seventh and eighth days. Further elevations of temperature were then observed by his doctor, and he was first seen by one of us (S. J. H.) on the eighth day. The patient was ill and toxic. He had a temperature of 102° F. and a pulse rate of 120; there was dullness under the right scapula extending upwards towards the apex, while anteriorly dullness extended from the sternum outwards to the right for some 3½ inches. The chest was explored posteriorly, and green pneumococcal pus was removed. A radiogram (Fig. 1 on Plate) showed two shadows in the right chest: the first, a subapical shadow, was considered to be a loculated empyema, but there was some doubt as to the nature of a second semicircular shadow extending outwards from the right mediastinum. The density of the second shadow was slightly greater than that of the apical collection; the three facts, that there was no cardiac displacement, that the shadow was not in contact with the diaphragm, and that there was no corresponding convexity of the left side of the pericardium, suggested that the shadow was that of a mediastinal collection of pus.

The subapical empyema was drained by the open method at the lowest point by resecting two inches of the fifth rib at the inner border of the scapula (L. N. P.). Only about 3 oz. of pus were evacuated, but a further quantity drained in the succeeding twenty-four hours. A tube was inserted. It was decided not to operate upon the mediastinal empyema at this stage, but to await events: the condition of the patient did not at once warrant a further operation, especially as the procedure might not prove to be very simple.

The patient continued with a leucocytosis of 18,000 to 20,000, and a temperature above 100°. On the seventh day after operation his temperature was 101°, and he was very restless. Quite suddenly the cough became more productive and purulent; during the next night the patient expectorated at least 3¼ pint of non-fetid yellow pus, and during the following day a rather smaller quantity, about 1¼ pint being expectorated in a sudden paroxysm. A second radiogram was now taken (Fig. 2). The apical collection was shown to be draining satisfactorily, and the semicircular mediastinal shadow was considerably smaller and less dense. The zone of aerated lung between the two loculi was broader. These appearances confirmed us in our opinion that the mediastinal shadow was pus and not growth.

For the next five days the temperature ranged from 99° to 101°, but on the fifth day it fell to normal. On each of these days an occasional paroxysm of coughing occurred, with the production of profuse yellowish sputum. The general condition of the patient improved, and his mentality became clearer. During these five days he was given breathing exercises and inhalations of oxygen containing 5 per cent. carbon dioxide, while postural assistance was attempted at the onset of each paroxysm. Pus continued to drain in small quantities through the tube. At the end of this period the leucocytosis was reduced to 16,000, the patient was much better, and his nights were less disturbed. He continued to have, approximately every other day, a paroxysm of coughing, which on three occasions resulted in the production of about a third of a pint of pus; after this the sputum became much less, and the leucocytosis on the twenty-second day after operation was 9,800. A third radiogram was taken on the twenty-eighth day (Fig. 3), and it showed that the apical loculus was almost completely drained and that the mediastinal shadow had shrunk to a narrow, almost invisible, strip.

Discussion

In the general textbooks the possibility of multiple loculi of pus in one pleural cavity is rarely mentioned, and even in textbooks devoted to thoracic diseases it receives scant notice. Simultaneous empyema on both sides of the chest is, of course, within the experience of most practising surgeons and physicians. We have not attempted a thorough search of the literature, but we may mention two recorded cases. Mackey (1925) reported an instance of a patient who had a large empyema in the left chest and two smaller empyemata in the right chest, one being on the anterior surface and one at the base; recovery followed drainage of the left and the right basal empyema and aspiration of the anterior right empyema. Van Allen (1929) published a case in which there were three loculi in the right chest—namely, at the apex, in the axillary region, and at the base, together with an *empyema necessitatis* pointing between the vertebral column and the vertebral border of the right scapula; the three separate cavities and the subcutaneous collection were all drained through separate incisions and the patient recovered.

In the case now reported the bacteriological examination of the pus removed by aspiration showed a pneumococcal infection, and according to the clinical course and physical signs it was of lobar type. The left lung never appeared to be affected by any pneumonic process. It may therefore be assumed that the two empyema foci originated independently from separate extensions of the pneumonia to the convex subapical pleural surface and to the inner mediastinal pleural surface, the walling off of the two loculi being accomplished by the fibrinous pneumonic reaction. The alternative pathology—that the empyema developed in relation to two peripheral lung abscesses—appears unlikely. The rarity of mediastinal empyema is largely due to the fixed state of the mediastinal surfaces of the lungs resulting from the entry of the various structures composing their roots. The absence of cardiac displacement is interesting in view of the different theories held as to the cause of cardiac displacement in pulmonary diseases. Although no lateral x-ray of the chest was taken it is probable that in this case the collection lay in the anterior mediastinum between the cardiac impression and the right surface of the pericardium, and therefore related only to the upper and middle lobes of the right lung.

The shadow of the mediastinal empyema had a sharp crescentic outline, and although its density was greater than that of the apical collection, yet it was possible to see the outline of the ribs through it, especially at its most peripheral part. The possibility that the shadow

represented a pericardial collection of fluid was definitely eliminated by the absence of general pericardial enlargement and by the existence of a zone of clear lung tissue between the inferior margin of the crescentic shadow and the right dome of the diaphragm. The question of mediastinal growth and of latent massive growth of the lung was considered. The regular sharp outline of the mediastinal shadow and its semi-translucent outer half were the points against growth, but until the second radiogram showed a diminution of the shadow we felt we could not definitely eliminate growth on purely radiological grounds. For clinical reasons we felt more certain, as the presence of typical lobar pneumonia led us to believe that the shadow must be that of pus and not of growth. Other possible diagnoses which were considered for the mediastinal shadow were dermoid cyst and the uncommon aneurysm of the descending thoracic aorta.

The treatment of the mediastinal collection gave rise to much anxiety. The patient was too ill for drainage of both collections of pus to be attempted at the same time. The decision to wait several days before contemplating a second operation was based upon two considerations.

First, the mediastinal abscess might increase in extent towards the anterior or posterior ends of the ribs, and in this position an operation for drainage would be easier. Secondly, the abscess might rupture into a bronchus and be followed by spontaneous recovery. The latter alternative was quite possible in view of the fairly close relation of the larger bronchi to the mediastinal surface of the lung. There was a definite risk of rupture of the abscess into the pericardium, with a sudden fatal catastrophe, but it was hoped that the successful open drainage of the subapical collection would relieve acute tension within the thorax and prevent such a rupture.

Summary

A case of double pneumococcal empyema, right subapical and mediastinal, is reported, with serial antero-posterior radiograms showing the progress of the case to recovery.

We desire to acknowledge our indebtedness to Dr. L. A. Rowden for the radiograms in this case.

The following international post-graduate courses have been arranged for 1935 by the Berlin Academy for Medical Post-Graduate Training: internal medicine, with special regard to gastro-intestinal ailments, March 4th to 9th—fee, RM. 40; disturbances of metabolism and of the glands of internal secretion, March 11th to 16th—fee, RM. 40, or, if taken with the earlier course, RM. 60; practical progress of x-ray diagnosis and therapy, particularly for internal ailments, March 18th to 24th—fee, RM. 70; special course in urology, March 25th to 30th—fee, RM. 70; occupation and sickness, with special consideration of expert opinion, April 1st to 8th—fee, RM. 40; special course for surgeons, April 29th to May 4th—fee, RM. 70; special courses in all branches of medicine, with bedside and laboratory practice, are held every month—fee, RM. 50 to 80 for eight lessons of two hours each. Programmes and further particulars are obtainable from the Academy, Berlin, N.W.7, Robert-Koch-Platz 7 (Kaiserin Friedrich-Haus). Foreign doctors receive a 25 per cent. reduction of fare on the German railways (Reichsbahn). By using "registered marks" they can reduce the cost of sojourn, but for this purpose their home bank should be consulted before departing for the trip.

UVEO-PAROTID TUBERCULOSIS

A REPORT OF THREE CASES

BY

S. E. TANNER, M.D. LOND., M.R.C.P.

HONORARY ASSISTANT PHYSICIAN, LEICESTER ROYAL INFIRMARY
AND

A. L. McCURRY, M.D. BELF., D.O.M.S.

HONORARY ASSISTANT OPHTHALMIC SURGEON, LEICESTER ROYAL
INFIRMARY

(With Special Plate)

Uveo-parotid tuberculosis is the name which has been suggested recently by Garland and Thomson¹ for that clinical syndrome—originally described by Heerfordt² in 1909—which is characterized by inflammation of the uveal tract, enlargement of the parotid glands, and, in some cases, paralysis of cranial nerves, usually the facial. They published a review of forty-seven cases from the literature, including the clinical and post-mortem appearances of one of their own. The conclusions they came to were that: (1) the condition was caused by "tuberculosis of a particularly fibrosing and non-caseating type"; (2) it ran a chronic course with a well-marked tendency to spontaneous recovery; and (3) when death occurred, which was rare, it was due to miliary tuberculosis.

The same aetiological factor had been suspected previously by Continental writers, and by Souter³ and Dorrell⁴ in this country. In the past, the condition had been referred to as "febris uveo-parotidea subchronica" (Heerfordt) or "uveo-parotitic paralysis" (MacBride),⁵ the latter because some cases presented symptoms of a polyneuritis. Most of the reports have appeared in Continental journals; only a few in those of this country. As they have appeared mainly in ophthalmological journals Garland and Thomson suggested that the condition has not received widespread recognition. This is probably true. Since reading their paper we have ourselves recognized and had under observation three examples of it.

Case 1

The patient, a married woman aged 35, was seen for the first time on March 25th, 1933, in the ophthalmological outpatient department, complaining that both eyes ached and that the vision of the right eye was blurred. These symptoms had come on gradually during the previous three weeks. The right eye showed a mild attack of iridocyclitis, some fine keratitis punctata being present. The fundus was normal. Three days later she developed a similar attack of iridocyclitis in the left eye, and, in addition, swelling of the left parotid gland and a paresis of the left facial nerve. Her condition remained unchanged until May 2nd, when optic neuritis was found in both eyes, more marked in the left. About this time also the patient complained of difficulty in swallowing, dryness of the mouth and throat, and that when she swallowed liquids some returned through her nose. She was admitted to hospital on May 15th for further investigation.

Apart from one child who had suffered from tuberculous peritonitis, there was no history of tuberculosis in her family. She had never had any previous trouble with her eyes, or any affection of the ear, nose, or throat, and she had not lately been in contact with mumps. On going more closely into her history it appeared that she had been losing weight and sweating profusely at night for about twelve months. The patient was an intelligent woman, of good colour, weighing 7 st. 8 lb. At the time of admission the iridocyclitis in both eyes showed signs of improving, but there was considerable swelling of both optic disks. No haemorrhage, exudates, or tuberculous nodules were seen. There was weakness of the muscles of the left side of the face, with some slight impairment in the movements of the soft palate. There was no affection of any other cranial nerves, neither was there

any tremor or ataxia, nor any change in sensations or in the reflexes. There were no signs of disease in the lungs or cardiovascular system. The left parotid gland was uniformly enlarged, but painless. Her teeth were in good condition, with no evidence of disease on x-ray examination, and there were no abnormalities in the nose, throat, or ear. There were no palpable lymphatic glands, and the spleen was not felt. The temperature during three weeks under observation remained normal; the urine was also normal.

Special Investigation.—Blood count: red cells, 5,116,000 per c.mm., haemoglobin, '92 per cent.; colour index, 0.9; average diameter, 7.4 μ ; leucocytes, 4,375 per c.mm.; polymorphs, 51 per cent.; lymphocytes, 31 per cent.; mononuclears, 15 per cent.; eosinophils, 2 per cent.; basophils, 1 per cent. Wassermann reaction of blood, negative. Cerebro-spinal fluid: pressure 140 mm. of water, clear; no coagulum on standing; cells, 1 per c.mm.; protein, 0.04 per cent.; chlorides, 0.7 per cent. Lange test, negative; Wassermann reaction, negative; cultures, sterile. X-ray examination of skull revealed no abnormalities; sinuses clear. The skiagram of the chest showed opacities in mediastinum, which were suggestive of enlarged lymphatic glands; the lung fields were clear. Electrocardiogram revealed no abnormalities. There was no evidence of salivary calculus on x-ray examination. Mantoux test, negative.

Progress.—The facial paresis improved and disappeared in about four weeks. The parotitis also subsided in about the same period. The optic neuritis, however, persisted for five months. The patient was seen in April, 1934—that is, one year after the onset of her illness. Her general condition had improved, her weight had increased by two stone, and she had no night sweats. A little nodular thickening behind the angle of the jaw was the only evidence that there had been any affection of the parotid gland. There was no facial weakness present. The condition of the eyes was satisfactory, there being no sign of any active iridocyclitis and no evidence of optic neuritis or atrophy. Her vision, fields, etc., were normal. The x-ray examination of the chest revealed the remarkable fact that the mediastinal opacities previously noted had almost completely disappeared.

Case 2

A married woman, aged 54, was admitted to a surgical ward on July 7th, 1931, under the care of Mr. R. S. Lawson, with a history of swelling of both sides of the face, of eight weeks' duration on the right, and seven weeks' on the left; of weakness of the left side of the face for five weeks; and inflammation of the left eye for three days. The facial paresis, which had come on suddenly and had tended to improve, involved the whole of the left side, including the eyelids. Both parotid glands were found to be uniformly enlarged and painless, and both eyes showed signs of iritis, the fundi being normal. There was nothing of note in her family history, and apart from a chronic cough, of which she had complained for some years, she had not suffered from any illness. She had not been in contact with mumps or any other infectious disease. There were no abnormal signs in the cardiovascular system. The skiagram of the chest revealed markedly exaggerated root shadows on both sides, with much undue mottling in the upper and middle zones, especially on the right side. Portions of each parotid gland were removed for microscopical section, and in both were demonstrated areas of chronic inflammation with numerous endothelial cells and giant cells—the whole picture typical of a tuberculous lesion. Tubercle bacilli were demonstrated. The patient remained in hospital for three weeks. During that time there was a gradual improvement in the condition of the face, and the parotitis subsided to a considerable degree. There was no pyrexia.

Following her discharge from hospital, she was not seen again until September, 1933, when she was readmitted for further examination. There were no visible swellings of the parotid glands, and all that could be felt was a nodular thickening behind the angle of each jaw. Her general condition, however, had deteriorated, her cough had become more troublesome, and she had lost weight. There were signs of old iritis, with posterior synechiae, and deposits on the anterior surface of the lenses in both eyes. In addition, there were

numerous opacities in the vitreous of each eye, but the fundi appeared normal. A little weakness of the left side of the face was still present; this was the only abnormality in the central nervous system. There was a slight impairment of the percussion note over the right apex with harsh breath sounds; a few rhonchi were scattered throughout both lungs. The skiagram of the chest showed very little change from the previous one. The cardiovascular system was normal, and there were no changes in the electrocardiogram. The urine was normal. The blood count gave the following figures: red cells, 5,249,000 per c.mm.; haemoglobin, 95 per cent.; large mononuclears, 4 per cent.; eosinophils, 3 per cent. The blood Wassermann reaction was negative, and the Mantoux test positive. There were no abnormalities in the ear, nose, or throat, and the teeth were in good condition.

The patient has been seen at regular intervals until the present time. Slight ciliary injection of both eyes has occasionally been noted, but there has been no return of the acute iritis. Her general condition has not been satisfactory, her cough still remaining troublesome and the radiological appearances in the chest having become more marked, particularly in the right lung. There is no doubt that she is suffering from chronic pulmonary tuberculosis of the fibroid type.

Case 3

A married woman, aged 41, was seen originally on August 27th, 1927, when she complained of a "mist over both eyes" for three weeks. Iridocyclitis, with posterior synechiae and keratitis punctata, was present in both eyes, the right being the more affected. Four weeks later a swelling of the left parotid gland appeared, and was followed in a few days by facial paralysis on the same side. There were no other signs of disease of the nervous system. The parotitis subsided in a few weeks, but the facial paralysis persisted. The iridocyclitis progressed, particularly in the left eye, where the pupillary area gradually filled up with exudate, and in the course of the following year became opaque. The right eye at this time showed extensive posterior synechiae. The blood Wassermann reaction was negative. There were no physical signs in the chest, but the radiological examination revealed evidence of chronic pleurisy on the right side. Her cardiovascular system was normal. There were no abnormalities in the ear, nose, or throat, and her teeth were in good condition. The only noteworthy fact in her family history was that her mother had died from pulmonary tuberculosis. The patient has remained under observation until the present time. Her general health has been good, and there has been no alteration in the condition of her eyes.

Discussion

Manifestations of uveitis, preceded or followed by signs of parotitis in a short space of time, occurred in these three, as in all the reported cases of uveo-parotid tuberculosis. Each group of symptoms developed rapidly at the onset, but whereas the eye changes tended to persist, the parotitis subsided quickly and did not recur. The facial paresis, of a lower motor neurone type, was probably a consequence of the inflammation in the parotid gland. This was strongly suggested by the fact that it appeared soon after the parotitis in each case, and in the two cases in which the latter was unilateral the paresis was on the same side.

The optic neuritis, dysphagia, and regurgitation of fluids through the nose which were seen in Case 1 were symptoms of a different causation. They have been noted in previous reports; optic neuritis and dysphagia were present in Heerfordt's original cases. We regard them as evidence of a toxic neuritis. Dysphagia has been said to be the result of dryness of the mouth and throat from lack of salivary secretion. That the latter might be a factor in its causation cannot be denied, but when it coexists with regurgitation of fluids through the nose, paresis of the pharyngeal muscles is probably a more potent cause. Widespread affection of the nervous system

in association with the syndrome has been reported by MacBride,⁶ in a woman of 43, with double parotitis, iridocyclitis, paresis of the face, legs, and arms, dysphagia, and some deafness. Feiling and Viner⁷ also reported a case in which there was an absence of knee- and ankle-jerks, and paraesthesia. Pyrexia, which is said to occur in about half the cases in the early stages of the syndrome, was absent during the period ours were under observation.

Garland and Thomson put forward strong evidence to show that tuberculosis was the main aetiological factor in this syndrome of uveitis and parotitis. As far as our cases are concerned, Case 2 was the only one in which a tuberculous infection was definitely proved.

In Case 1 the aetiology was not so clear. After a period of twelve months of indifferent health, with night sweats and loss of weight, the syndrome appeared, and at the same time radiological evidence of mediastinal adenitis was found. It is important to determine whether the adenitis was present before, and was, in fact, the focus of infection giving rise to the syndrome, or whether it developed with, and as part of, the condition. Its disappearance was coincident with the general improvement in the patient. The prodromal symptoms, for which no other cause was discovered, can be explained by its presence. Further, we have not found in the literature a single report in which adenitis developed concurrently with uveitis and parotitis. We are therefore of the opinion that it was the responsible agent in the case. The question then arises as to its pathology. Was it tuberculous? Here again it is impossible to give a categorical answer. There were no signs of disease in the lungs, and the tuberculin test was negative. Too much reliance, however, cannot be placed on the latter test, because, as d'Arcy Hart⁸ has pointed out, a negative finding cannot be relied upon to exclude a tuberculous infection. The character of the early symptoms and the subsequent course of the illness are very suggestive of a tuberculous adenitis.

In Case 3 the evidence was admittedly meagre, but the family history and the x-ray examination of the chest point to a tuberculous origin.

As we have already stated, when death occurs it is due to miliary tuberculosis. This statement is based on the only three necropsies recorded. An interesting feature of two of these, Souter's and Garland and Thomson's, was the presence of tuberculosis of the cardiac musculature. We were unable to demonstrate by clinical or electrocardiographic investigation any such involvement in our patients.

Summary

Three cases of uveo-parotid tuberculosis are recorded. In the first, uveitis and unilateral parotitis were accompanied by facial paresis, optic neuritis, dysphagia, and palatal paresis. Mediastinal adenitis, probably tuberculous in nature, was demonstrated. In Case 2 uveitis and bilateral parotitis, and left-sided facial paresis occurred. A biopsy of the parotid gland gave definite evidence of tuberculosis, and there was also evidence of the same infection in the lungs. The third case showed extensive uveitis in both eyes, leading to blindness in one, unilateral parotitis, and facial paresis; there was a family history of tuberculosis and radiographical evidence of chronic pleurisy.
